HARMSWORTH SELF-EDUCATOR

1906

Vol. II. Pages 913—1776

A KEY TO THE HARMSWORTH SELF-EDUCATOR

At the heading of each article in the Self-Educator is the number of the group to which the article belongs, and a reference to this key indicates precisely the place of the article in the scheme of the book. This key, therefore, enables the student at any time to understand what has preceded and what is to follow any part of the work to which he may happen to turn.

Group 1.

Agriculture. Beekeeping. Gardening.

Farming. In all its Branches. Dairying. Poultry.
Beekeeping. A Practical and Commercial Course.
Gardening. How to Get the Most out of a Minimum of Land. Gardening for Pleasure and Profit. Market Gardening.

Group 2.

Art. Architecture. Glass. Earthenware. Carving.

Art (Theory and Training). Painting. Sculpture. Architecture (Theory, styles. Practical Training). History of Art.
Glass and Earthenware. Including Pottery.
Carving. Wood. Bone. Ivory. Horn. Tortoiseshell.

Group 3.

Biology. Psychology. Sociology. Philosophy. Religion.

Biology. Including Evolution. Paleontology. Heredity. Anthropology. Ethnology.
Psychology. Including Psychical Research.
Sociology. Including Political Economy.
Philosophy and Religion. History and Systems. Christianity.

Group 4.

Building. Cabinet Making. Upholstering. Fire.

Building. Excavating. Drainage. Manufacture of Bricks, Limes, and Cements. Bricklaying. Clay Wares. Reinforced Concrete. Masonry. Carpentry. Slates and Tiles. Plumbing. Joinery. Foundry and Smiths' Work. Painting. Paper Hanging and Glazing. Heating, Lighting, and Ventilation. Building Regulations. Building Abroad. In Business as a Builder.
Cabinet Making and Upholstering.
Fire. Fireproof Materials. Fire Prevention. Fire Extinction.

Group 5.

Chemistry and Applied Chemistry.

Chemistry. Inorganic and Organic. Chemistry of the Stars.
Applied Chemistry. Acids and Alkalies. Oils (Fixed Oils and Fats; Waxes; Essential Oils and Perfumes; Paints and Polishes) Candles. Soaps. Glycerine. Glues and Adhesives. Starches. Inks. Tar and Wood Distillation. Matches. Celluloid. Manure. Waste Products. Petroleum. Paper Making (including Paper Staining and Uses of Paper). Photography.

Group 6.

Civil Service. Army and Navy.

Civil Service. Municipal. National. Imperial.
Army and Navy. How to Enter Them.

Group 7.

Clerkship and the Professions.

Clerkship and Accountancy. Complete Training. Bookkeeping.
Banking. The Whole Practice of Banking.
Insurance. Life, Fire, Accident, Marine.
Auctioneering and Valuing. Practical Training.
Estate Agency. Departments and Officials of a Great Estate. Training a Land Agent.
Medicine. Training of a Doctor. Specialists. Veterinary Surgeons. Chemists and Druggists. Dentistry: The Dental Mechanic. Home and Professional Nursing.
Church. How to Enter the Ministry of all Denominations.
Scholastic. Teachers. Professorships. Governesses. Coaches. Tutors.
Secretaries, etc. Institution Officials. Political Organisations. Lecturers.
Law. Solicitors and Barristers. Personal and Commercial Law.

Group 8.

Drawing and Design.

Drawing. Freehand. Object. Geometrical. Brush. Memory. Light and Shade.
Technical Drawing. For Engineers; Coppersmiths, Tinmen, Boilermakers; Architects; Stonemasons; Carpenters and Joiners; Plumbers.
Design. Book Decoration. Textiles. Wall Papers. Metal Work.

Group 9.

Dress.

Dress. Dressmaking. Underclothing. Children's Clothing. Tailoring. Millinery. Men's Hats. Furs and Furriers. Feathers. Shirts and Collars.

Group 10.

Electricity.

Electricity. Electrical Engineering. Telegraphs and Telephones (including operation of). Cables and Insulated Wire. In Business as an Electrical Engineer.

Group 11.

Civil Engineering.

Civil Engineering. Surveying. Varieties of Construction. Machines Employed. Roads. Bridges. Tramways. Railways. Water Supply. Sewerage. Refuse. Hydraulics. Pumps. Harbours. Docks. Lighthouses. Foreign Work. In Business as a Civil Engineer.

Group 12.

Mechanical Engineering. Military Engineering. Arms & Ammunition.

Mechanical Engineering. Applied Mechanics. Workshop Practice. Tools (Hand and Miscellaneous. Machine Tools. Portable Machine Tools). Machines and Appliances (A General Guide to Construction. Clocks and Watches. Scientific Instruments).
Military Engineering. Pontoons. Bridges. Fortifications. Rafts. Trenches. Passing Rivers. Conditions in Peace and War.
Arms and Ammunition. Manufacture of Arms and Explosives.

Group 13.

Geography. Astronomy.

Geography. Physical. Political. Human. Commercial.
Astronomy. A Survey of the Solar System.

Group 14.

Geology. Mining. Metals and Minerals. Gas.

Geology. A Course in Geology.
Mining. The Practice of Mining: Coal, Gold, Diamonds, Tin, etc.
Metals. Metallurgy. Iron and Steel. Iron and Steel Manufactures. Metal Work. Cutlery.
Minerals. Mineralogy. Properties of Minerals.
Gas. Manufacture of Gas.

Group 15.

History.

History. A Short History of the World.

Group 16.

Housekeeping and Food Supply.

Servants. Qualifications and Duties of Every Kind of Servant.
Cookery. A Practical Course.
Laundry Work. Washing. The Laundry as a Business.
Foods and Beverages. Milling. Bread-making. Biscuits and Confectionery. Sugar. Condiments. Fruit. Fisheries. Food Preservation. Catering. Brewing. Wines and Ciders. Mineral Waters. Tea. Coffee. Chocolate. Cocoa.

Group 17.

Ideas. Patents. Applied Education.

Ideas. The Power of Ideas in Life. Brains in Business.
Patents and Inventions. How to Protect an Idea.
Applied Education. Application of Education in Every Walk of Life.

Group 18.

Languages.

Latin. English. French. German. Spanish. Italian. Esperanto.

Group 19.

Literature. Journalism. Printing. Publishing. Libraries.

Literature. A Survey of the World's Great Books and their Writers. Poetry. Classics. Fiction. Miscellaneous. How to Read and Write.
Journalism. A Guide to Newspaper Work, with Practical Training.
Printing. Composing by Hand and Machine. Type Cutting and Founding. Engraving and Blocks. Bookbinding and Publishing.
Libraries. Officials and Management of Libraries.

Group 20

Materials and Structures. Leather. Wood Working.

Materials. The Characteristics and Strength of Materials.
Structures. The Stability of Structures.
Leather. Leather Industry. Leather Belts. Boots and Shoes. Saddlery and Harness. Gloves. Sundry Leather Goods.
Wood Working. Design and Operation of Wood Working Machinery. Wood Turning. Miscellaneous Woodwork.

Group 21.

Mathematics.

Mathematics. Arithmetic. Algebra. Plane Trigonometry. Conic Sections.

Group 22.

Music. Singing. Amusement.

Music. Musical Theory. Tonic Solfa. Tuition in all Instruments. Orchestration. Conducting. Bell Ringing. Manufacture of Musical Instruments.
Singing. The Voice and Its Treatment.
Amusement. Drama and Stage. Business side of Amusement. Sports Officials.

Group 23.

Natural History. Applied Botany. Bacteriology. Natural Products.

Natural History. Kingdom of Nature. Its Marvels, Mechanism, and Romance. Animal Life. Flowers. Plants. Seeds, Trees, Ferns, Mosses, etc.
Applied Botany. Tobacco & Tobacco Pipes. Forestry. Rubber and Gutta Percha. Basket and Brush Making. Cane Work. Barks (Cork, Wattle).
Bacteriology. Pathological and Economic.
Natural Products. Sources. Values. Cultivation.

Group 24.

Physics. Power. Prime Movers.

Physics. A Complete Course in the Science of Matter and Motion.
Power. A General Survey of Power. Natural Sources. Liquid and Compressed Air.
Prime Movers. Engines. Steam. Gas. Heat. Turbines. Windmills.

Group 25.

Physiology. Health. Ill-health.

Physiology. Plan of the Body. Digestive, Circulatory. Respiratory, Locomotor and Nervous Systems. The Senses.
Health. The Five Laws of Health. Personal Hygiene. Environment. State Medicine and the Public Health.
Ill-health. General Ill-health. Its Special Forms. Common Ailments and Domestic Remedies.

Group 26.

Shopkeeping. Business Management. Publicity.

Shopkeeping. A Practical Guide to the Keeping of all Kinds of Shops
Business Management. The Application of System in Business.
Publicity. Advertising from all Points of View As a Business.

Group 27.

Shorthand and Typewriting.

Shorthand. Taught by Pitmans. Typewriting. Working and Management of all Machines.

Group 28.

Textiles and Dyeing.

Textiles. The Textile Trades from Beginning to End.
Dyeing. Dyes and Their Application.

Group 29.

Travel and Transit.

Travel. How to See the World. The Business Side of Travel.
Transit. A General Survey of Means of Communication.
Vehicles. The Construction of Air, Land and Sea Vehicles.
Railways. The Management and Control of Railways.
Ships. Shipbuilding. Shipping. Management of Ships.

THE LIFE HISTORY OF WHEAT

Cereals are Cultivated Grasses. Structures of the Wheat Plant. The Flowers. The Grain. Germination. Varieties

Continued from page 912

By Professor J. R. AINSWORTH DAVIS

THE beginnings of agriculture in Western Europe have been traced back to the remote pre-historic times when weapons and implements were made of polished stone, and the valuable properties of metals were unknown. We can only conjecture as to the manner in which the cultivation of wild plants began; but it has been suggested that the practice arose in the superstitious custom of burying berries and grains with the bodies of deceased friends, to serve as food for their ghosts. The plants springing up from these offerings would no doubt be more vigorous than their wild congeners, and the discovery that the turning up of the soil had to do with such a result might ultimately be made. In some such way as this the importance of tillage no doubt gradually came to be independently perceived by wild tribes living in different localities.

Our Debt to the Grasses. By taking advantage of the stores of nutritive matter that grasses lay up for the benefit of their offspring, to say nothing of the value of the plants themselves as food for domesticated animals, the evolution of civilisation has been immensely furthered. Wheat, barley, oats, and all other cereals are simply cultivated grasses, the value of which has been enormously enhanced by the increase in size and number of their grains as the result of thousands of years of tillage. Till now it is estimated that wheat, the type we are considering, is capable of yielding some 2,000 pounds of food per acre. How best to increase this yield and to extend the wheat-growing area are among the most pressing economic problems of the present time, and their solution will obviously be more and more urgent as time goes on.

Structure of the Wheat-plant [158]. Without repeating what has elsewhere been said about the characters of grasses in general, it may be remarked here that the hollow stems are eminently adapted for supporting the heavy ears, and that the main root of the seedling remains undeveloped, the root system consisting of a multitude of branching fibres which ramify through the soil. As, from the nature of the case, the plant becomes more and more top-heavy as its value increases, it is clear that the selection of varieties with a vigorous and extensive root system is a matter of great importance. Besides which, the soil must be sufficiently firm to afford a good hold. Failing these conditions, the two great enemies of the crop—wind and rain—especially when acting in conjunction, may play sad havoc. And these conditions have much to do with determining the extent of the area available in the future as wheat-land.

Flowers of the Wheat. An ear of wheat (*Triticum vulgare*) consists of numerous crowded spikelets, each of which contains several flowers invested in scaly glumes or bracts [159]. In "bearded wheat" some of these are drawn out into long threads or awns. On examining a single flower [160], we find that it possesses a pair of small scales, the *lodicules*, which possibly represent the covering leaves or perianth—*i.e.*, the conspicuous part of an ordinary sort of flower. There are three stamens with long slender filaments, to which the anthers are so attached that they swing about very easily. They produce an abundance of dust-like pollen. The pistil consists of a single carpel, crowned by two feathery styles, of which the branches serve as stigmas or pollen-catchers. The swollen base of the pistil—*i.e.*, the ovary—is destined to become the wheat-grain, and contains a single ovule or incipient seed.

Pollination and Fertilisation. The flowers do not open thoroughly unless the temperature is a little over 60° F., and here the lodicules play an important part, for they swell up and force the investing scales apart. This usually takes place in the morning. The anthers of the projecting stamens are easily moved by the wind, which carries some of their pollen to other flowers, thus effecting crossing, the feathery styles catching any grains that may chance to be blown against them. A certain part of the pollen remains in the same flower, and may effect self-pollination, which is effective. In unfavourable weather the flowers do not open at all, and crossing cannot then take place. Flowering begins and ends the same day. The grains which result from crossing are larger and healthier than those produced by self-fertilisation.

Structure of the Wheat-grain. A grain of wheat is of elongated shape, with a groove running along one side [161]. It is a fruit, and not a seed, and is covered by a rather thick membrane representing the wall of the ovary and the seed-coat, which are closely adherent. The great mass of the grain is a food store for the embryo, which may be seen at the base of the ungrooved side [162], and consists of a primary shoot (*plumule*) and a primary root (*radicle*), around which is folded the single seed-leaf or *cotyledon*. The central part of this is termed the *scutellum*, and is closely applied to the food store or endosperm [163].

Examination of a microscopic section of part of the grain [164] shows externally the membranous investment alluded to above. This is the "bran," which is retained in brown bread, and removed in white. Under this is a layer of "gluten-cells," containing granules of albuminous nature. Since this is largely milled away in grains destined to make white bread, this bread is less nutritious than brown bread. Within this again, larger cells crowded with starch make up the greater part of the endosperm.

Germination of Wheat. Given moisture, air, and a fairly high temperature, the wheat-grain begins to germinate [165]. The plumule elongates and pushes its way above ground, to give rise to the stem and leaves, while the radicle breaks out and grows down into the ground. Its development, however, is soon arrested, and most of the wheat-roots are derived from the lower part of the stem.

Until the seedling is able to get its own living, it feeds upon the endosperm. The nutritive matters in this have to be converted into a soluble form before they can be absorbed by the embryo. This is the work of the scutellum, which produces substances known as *ferments*, that digest the endosperm in much the same way that food is digested in the animal body. That is to say, the practically insoluble starch and gluten are converted into soluble materials (sugar in the case of starch), which are absorbed by the scutellum, and diffuse into the growing shoots and roots. By the time the endosperm is used up, the seedling is able to draw upon the air and soil for its food supply.

Crossing Varieties of Wheat. As in the case of other domesticated plants, a number of different varieties or races of wheat have come into existence in the course of time [166–7]. It has been found possible to cross these artificially by transferring the pollen of one variety to the stigmas of another, with remarkable results, for the ears of some of the mongrel plants so produced are of extraordinary size [168–71]. Experiments of this kind, conducted on wheat and many other plants, have yielded valuable data on which to found theories of heredity, careful observations being made and tabulated of the characters inherited from the parents. Such experiments are not particularly difficult to conduct in many cases, and are of great importance both scientifically and economically. [For details see BIOLOGY.] The essence of the matter in the latter aspect is that it appears to be possible to produce mongrel types which combine the desirable character of the parent forms, or it may be to eliminate those which are undesirable. This is but one of many examples which illustrate the value of science in relation to industry, and lead to the conclusion that unless the Government of this country is prepared to endow scientific research to a much larger extent than has so far been the case, we shall in the end be left far behind—commercially—by Germany, the United States, and other countries which are fully alive to the vast importance of the matter.

Sources of our Wheat Supply. In round numbers we may estimate the annual consumption of wheat in the United Kingdom at 30,000,000 quarters, of which only 6,000,000 quarters are home-grown. Unfortunately, owing to external competition, the amount of British wheat produced has been rapidly declining since 1870, and is continuing to do so, which has not only a disastrous effect in furthering the depopulation of our rural districts, but makes us increasingly dependent on foreign countries, especially the United States and Russia, for the most important item in our food-supply. Unfortunately, too, average British wheat compares unfavourably with foreign, for it contains a larger amount of moisture, and a smaller percentage of nitrogenous matter (gluten).

Less than one-third (about 27 per cent.) of imported wheat and flour is derived from British possessions, but, luckily, the proportion is on the increase, and we may hope to see the time when the Empire is able to feed itself. Large quantities are grown in the more temperate parts of India, and in Australia, but it is mainly to Canada that we must look as an increasing source of supply.

Canadian Wheat. The vast plain of Central Canada presents very large areas which are eminently suitable for wheat-growing. The soil is a stiff clay, which not only affords firm support to the roots, but is also very retentive of moisture. And it is covered by an ancient and very rich deposit of loam, which serves as a sort of natural manure. So much is this the case that, in some instances, the crop has been continuously grown for from 20 to 30 years without the application of any artificial fertilisers. Of course, the time will ultimately come when these will have to be applied in all cases, but that time is not yet.

The long summer days of Canada are extremely favourable to the ripening of grain, and their influence is enhanced by the south-west anti-trade winds, which, after blowing over the Rockies, are warm and dry. Despite the dryness of these winds, an abundant supply of moisture is available, for the great cold of winter furrows the ground with deep cracks, in which snow collects, being stored up, as it were, in underground reservoirs. When this snow melts, it yields the requisite water.

It may be added that the facilities for water-carriage to the Atlantic sea-board are unrivalled, nor are there great difficulties in the way of railway construction. The Canadian farmer has, it is true, to contend with summer frosts and floods, but the former are successfully combated by lighting fires of damp straw ("smudge-fires") to the north side of the crop on nights when frost is threatened. And it seems probable that an increase in the area of tillage will gradually more or less obviate the danger of floods, by averaging the distribution of rainfall, and tree-planting may also do something in the same direction.

SHORING AND UNDERPINNING

The Use and Construction of Raking and Flying Shores, and of Needles for Underpinning. Methods of Dealing with Dangerous Structures

By Professor R. ELSEY SMITH

SHORING consists in providing temporary support to a building by means of a system of wooden struts resting on solid ground or against another building. It is employed in cases where buildings show signs of failure due to sinking of the foundations, vibration of machinery, or other causes, and demands much judgment and very great care in execution.

It is also used where a building which is attached to one or more other buildings is to be taken down for rebuilding. In a row of houses —*e.g.*, each one gives lateral support to its neighbours, and were a single house in a row removed there would be great liability of damage to the houses which are on each side, and are entitled to the support previously afforded them, and shoring is erected to give this support temporarily until the reconstruction is complete.

A Typical Shoring Scheme. The key plan [60] represents three houses in a line, of which the central one is in course of reconstruction, while that on the left is to have the ground-floor taken out to insert a girder and shop front. It illustrates the position in which the various shores described hereafter are used.

Shores, as applied to walls constructed mainly of brick, are of two principal types. *Raking shores* [58] are those one end of which rests on the ground, while the other is inclined against the face of the wall to be supported. *Flying shores* [56] are those placed horizontally between two buildings. In the case of raking shores, if the building to be supported be a low one, a single strut may suffice, but in most cases, where the buildings consist of several storeys, a *system* of shores must be used—two or more struts in the same plane, abutting against and steadying the wall at different levels. Wherever possible, the head of each strut should be arranged at or just below the level of a floor, where the wall is stiffened internally and is best able to resist external pressure. The object of shoring in the case of dangerous walls is not, as a rule, to force back into position a wall that is out of the perpendicular, for any such attempt might result in disaster, but to prevent any further movement of the wall till it can be dealt with in a permanent manner.

Constructing a Shore. A shore is constructed as follows [61]. A wall-piece is placed vertically against the wall to be supported. This is usually of considerable length, 9 by 3 in. thick, and is held to the wall by holdfasts carefully driven. If the wall be bulged or uneven, packing must be placed between it and the wall-piece to secure an even bearing against the wall. Where the head of the shore abuts [55], a 3 or 4 in. square hole is perforated through the piece, and a bat or half brick is removed from the face of the wall. A short timber, or *needle* is placed through the hole entering the wall where the bat is removed, and above it a block of wood, termed a *cleat*, is spiked to the wall-piece, and thus a firm abutment for the head of the shore is formed.

For the foot of the shore [57] a stout timber is provided, termed the *sole-piece*. If the ground be good, it may be carefully bedded upon it; but if the ground be soft, a small platform of stout planks, or in some cases even of concrete, will be necessary. Should a vault exist where the foot of the shore comes, it must be supported with dead shores—hereafter described—or, better, the shore must be taken through the vault to the solid ground. The sole-piece is not placed horizontally, nor is it perpendicular to the shore, but at an intermediate angle.

The sole-piece and wall-piece being in position, the shore itself is cut to the required length. The head is notched to fit round the needle and prevent any possibility of lateral movement, and the underside is cut so as to rest against the wall-piece. The foot is also cut to a bevel to correspond with the inclination of the sole-piece, and at the back of the shore a small notch is cut to allow of a crowbar being inserted. The shore is placed in position, and if the wall be dangerous great care must be exercised to prevent any damage to the wall during this process. The foot rests on the sole-piece with the head against the needle, at first loosely, but with the help of a crowbar the foot is gradually moved forward along the sole-piece until the notch is tight up against the needle. If it be moved beyond this, there will be a tendency for the head to lift the needle and damage the wall. When in position the foot is secured by *dog-irons* [54]. These are bars of iron with ends bent at right angles and pointed. They may be driven into the foot and the sole-piece, or a cleat may be fixed behind the foot. In the case of dangerous walls this method of fixing is better than tightening by wedges as less likely to disturb the brickwork. The shore is stiffened to resist transverse strain or buckling, by braces formed of boards placed on either side and securely nailed to it at one end, and to the lower part of the wall-piece at the other.

A System of Shores. Where a system of two, three, or four struts—one above another—is employed, the method is similar [58]. The length of the wall-piece is increased to correspond with the height of the building, and the head of each shore is prepared as described, and has a needle provided for its abutment. The feet are brought close together on the sole-piece, and each shore in the system is of a different length and at a different angle. In such a system, when the shores are in position, a strip of hoop-iron is wound tightly round near the foot and nailed to the various timbers, binding them together, and the braces extend from the wall-piece to the outermost shore, and are nailed to the intermediate ones. This occurs at two or three points in the height in each case, starting from the wall-piece just below the head of a shore. Great rigidity is thus secured.

Shoring High Buildings. With lofty buildings it may prove difficult to obtain timbers of sufficient length for the outermost shore. In such a case, when the last raking shore is fixed, another piece of timber is placed against the back of it, resting on the sole-piece. The top is cut to a bevel, and the foot of the shore rests on the top of this post, the head being formed as usual. This is termed a *riding shore*, and cannot be levered into position, but must be wedged with folding wedges of oak inserted between the upper and lower parts of the shore, driven in from each side, care being taken not to lift the rider more than is required just to tighten it.

The number of such systems required to steady any given wall will vary with the circumstances, and in particular with the condition of the wall itself, depending on whether the brickwork is sound and well constructed, or tending to disintegrate. They should not be more than 12 or 15 ft. apart, and may be much closer. If the wall is pierced with window openings, the shore systems must correspond with the piers between them.

Shoring is sometimes required in connection with the timbering of excavations. The horizontal struts used in wide excavations form practically flying shores, which will be described later; but an excavation may be too wide to allow of strutting each side from the opposite one. In such cases raking struts, or shores, must be provided to sustain the walling pieces, and they can often be used with greater efficiency than in the case of a building, as it is frequently possible to place them at a comparatively low angle with the horizon.

Work of the Shore. The work required of a shore, or shore system, is to resist the tendency of a wall to fall outwards, by pressure behind it, which is greatest when just sufficient to overturn the wall. This pressure, or force, acts perpendicularly to the wall through the head of the shore. It would be best resisted by a strut also perpendicular to the wall; but, except in the case of flying shores, this cannot be provided. With a raking shore part of the force exerted is expended in holding up the wall vertically, and part only in resisting overturning, the amount depending on the inclination of the shore to the horizon, the lateral resistance being greatest when the inclination is low. An angle of 40° is useful, but so low an angle is rarely practicable, and angles from 60° to 75° with the horizon are very usual.

Formula of Forces in a Shore. The following formulæ may be used for calculating the forces acting upon a shore [61]. *

$$Q = \frac{W \times t}{2\,H},\ P = Q \tan\theta - \frac{w}{2},\ F = P \sin\theta + Q \cos\theta$$

Q = the overturning force, P = the force due to weight of wall above shore, F = the resistance to compression in the shore, W = the weight of wall, all in cwts., t = the thickness of wall at ground in feet, H = the height of the head of the shore from the ground in feet, θ = the angle of inclination between the shore and the horizon, and w = the weight of the shore itself in cwts. The dimensions of the shore, when F has been calculated, may be found by Rankine's or other formulæ for timber struts.

In a system of shores it is sufficient to calculate the outermost shore, and to use timber of the same size for all, and a builder will usually employ timber in stock for this purpose even if of somewhat larger scantlings than required.

The number and sizes of shores usually required in each system are: *

Height of wall.	Number of shores in system.	Scantlings of each shore in system
15 ft. to 20 ft.	2	5 in × 5 in.
20 ,, ,, 30 ,,	2	6 ,, × 6 ,,
30 ,, ,, 35 ,,	3	7 ,, × 7 ,,
35 ,, ,, 40 ,,	3	8 ,, × 8 ,,
40 ,, ,, 50 ,,	4	9 ,, × 9 ,,
50 upwards	4	12 ,, × 9 ,,

The material used for shoring is usually fir, Dantzic being particularly suitable on account of its straight grain. For very long shores, however, it may be difficult to obtain this timber of sufficient length, and pine is sometimes used. But this is more expensive, and is therefore avoided, when possible, for what is merely temporary work. The wedges should be of oak, as offering greater resistance to compression than fir, and the sole-piece may usefully be of the same material. Care must be taken to see that all bearing surfaces are truly cut, so that when in position they will be in contact all over.

Flying Shores. *Flying*, or *horizontal* shores [56] are employed wherever a suitable abutment can be secured above the ground level. Their most common use is when a house between two others is temporarily taken down and the buildings on each side require mutual support, but they may be employed across a court or street in the case of a dangerous building, with the consent of the owner of the opposite building, who is, however, at liberty to withhold it.

The great advantage of a flying shore is that the principal timber is placed perpendicularly to the face of the wall, and therefore directly counteracts the overturning force.

---

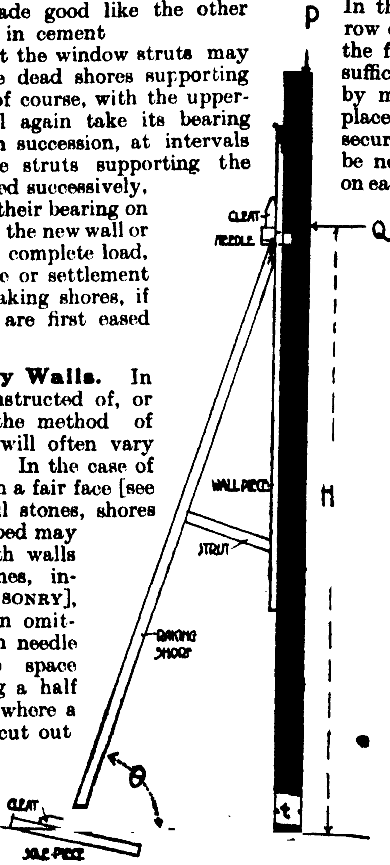
* C. Haden Stock. "Shoring and Underpinning."

of the wall, and upon this brickwork is built in cement under the lengths of wall between the needles, and the new brickwork is pinned up tight under the old. If possible, the levels should be adjusted so as to allow of an exact number of brick courses being used, but if this is not possible the necessary thickness may be made up with hard slates or tiles set in cement.

Striking Underpinning and Shoring. Seven days are usually allowed for setting, then the needles are gradually eased by loosening the wedges or lowering the jacks, so that the wall takes its bearing on the girder. They are afterwards removed, and the holes occupied by them made good like the other parts with brickwork in cement

When this also is set the window struts may be taken out, and the dead shores supporting the floors, beginning, of course, with the uppermost floor, which will again take its bearing on the wall. Then in succession, at intervals of a day or two, the struts supporting the lower floors are removed successively, and they in turn take their bearing on the wall; lastly, when the new wall or girder has received its complete load, and no signs of failure or settlement are observable, the raking shores, if they have been used, are first eased and then struck.

Shoring Masonry Walls. In the case of walls constructed of, or faced with stone, the method of applying the struts will often vary from that described. In the case of rubble walls built with a fair face [see MASONRY] and of small stones, shores similar to those described may be employed; but with walls built of larger stones, including ashlar [see MASONRY], the wall-piece is often omitted. The small wooden needle which fits into the space occupied by removing a half brick is not suitable where a large stone has to be cut out In this case a header of hard stone is inserted and allowed to project beyond the face of the wall, and beneath it a piece of oak is placed, to form a seating to receive the head of the shore.



61. DIAGRAM OF FORCES ACTING ON A SINGLE SHORE

Occasionally when great strength is required at some point in a wall, two systems of shores may usefully be employed close together; in such a case the systems are advantageously arranged not parallel to each other in vertical planes, but converging so that where the struts impinge upon the wall they are close together, while the feet and the sole pieces they rest in are wider apart, and if two such systems are well braced laterally, great strength and stiffness is secured.

Shoring Ruinous and Dangerous Structures. The method of dealing with ruinous and dangerous buildings will vary greatly with the nature of the structure and the extent and nature of the failure or damage. This is liable to so much variation that nothing but very general particulars can be given. The first essential is to steady and uphold the building to prevent its collapse. For this purpose raking or flying shores are usually employed. When the building has been temporarily secured, needling may take place to enable defective foundations or lengths of walling to be removed and reconstructed.

In the case of buildings supported on a row of detached piers or arches, in case of the failure and cracking of a pier, it may suffice to uphold the capital of the column by means of a strong frame of timber placed round it and strutted up from a secure base; but in other cases it may be necessary to shore up the two openings on each side of it upon a strongly-framed centre, such as is used for constructing an arch, and which will be described later.

Old Buildings. In all cases in which old buildings require to be dealt with, it is very necessary that they should be carefully examined, and the condition of the materials and structure ascertained, not merely on the surface of the wall, but in its heart. In many mediæval buildings walls are found constructed with a comparatively thin external skin of good masonry, while the heart of the wall is formed of rubble or concrete; if the lime used in forming the concrete was not originally of good quality this may have disintegrated. In such cases it is impossible to employ needling unless the core can be first rendered solid by the introduction of grouting [see BRICKLAYER]. It will usually be necessary to compute carefully the weight of the old building or the part of it which is to be dealt with; this is particularly necessary where any building of considerable height such as a tower has to be upheld, as the loads to be supported may be considerable. In such a position, too, there is often very considerable difficulty in finding adequate room for the necessary supports without seriously encroaching on the working space and rendering the work of reconstructing those parts of the structure that have to be reinstated extremely awkward and difficult. With structures of great height and weight the work may sometimes be quite as economically done by taking down and reinstating the work as by shoring and underpinning it; other considerations than cost may however render the latter course the better one.

TONIC SOL-FA

TONIC SOL-FA continued from page 807

Division of Pulses. Rests. How "Holds" are Indicated. The Theory of Transition. Major and Minor Modes

By J. CUTHBERT HADDEN

THUS are the individual full pulses of the various measures marked out. We have next to consider how the pulses themselves are divided and extended. Here, again, the same simple means are adopted ; for all time divisions and extensions whatsoever are indicated by just three symbols—the dot, the comma, and the dash. A pulse is divided into halves by placing a dot in the middle of it ; into quarters by a comma in the middle of each half (for you must show the half division first) ; and into thirds (" triplets " is the Staff term) by two inverted commas. When a note is to be continued from one pulse into the next, the continuation is indicated by a horizontal line (or dash). A little illustration may be made to include all these time forms :

|d :m .s |d :r .m |f :s,f.m,f |s :l‘s‘f |

|m :— |s :— |d :— |— :— ‖

The first measure introduces halves, the second measure quarters and thirds, and the last two measures show continued notes. Of course the continuation mark does not necessarily go always through a full pulse. Thus we may write :

|d :– .d |m :– .r |s :– .f,m |r :d ‖

where the continuation is for only a half-pulse. Similarly, a continuation may be carried into a third of a pulse, as here :

|d :— |–‘s‘f :m‘r‘m |s :— |–‘f‘r :d ‖

There are, again, other forms of quarter division of the pulse besides the four notes of equal length. A pulse may, for example, contain a half-pulse note and two quarter notes, as here, where at *a* the half-pulse comes first, while at *b* the two quarters come first :

(*a*) (*b*)
|d .s :m .r,m |s .f :m,r.d ‖

Another very common time division is shown in the following illustration, where we have a succession of pulses, each containing a three-quarter and a one-quarter note :

|d .,r :m .,f |s .,f:m .,r |m .,s:f .,r |d :— ‖

This time-form is frequently met with in marches and other music of a bold and swinging character.

In advanced classical music many curious and minute subdivisions will be met with, the time notation of which—from what he has already learnt—the student will, as a rule, readily understand from the context. Special note should, however, be made of the way in which sixths, eighths, and ninths are written. The following illustration is taken from the authorised " Tonic Sol-fa Time Chart," which the earnest student of the notation should always keep beside him for reference :

Eighths	*Sixths* (*Three Accents*)
l l ,l l .l l ,l l	:l l ‘l l ‘l l
Ninths	*Sixths* (*Two Accents*)
$\overset{3}{\text{l}}$ l ‘l $\overset{3}{\text{l}}$ l ‘l $\overset{3}{\text{l}}$ l	:l $\overset{3}{\text{l}}$ l .l $\overset{3}{\text{l}}$ l

Rests in Tonic Sol-fa are not indicated by characters, as in the Staff. The pulse, or part of a pulse, is simply left empty ; there is nothing in it to sing. Thus, at *a* there is a full pulse rest at the end of the measure ; at *b* a similar rest at the beginning of the measure :

(*a*) (*b*)
|d .t_1 :d |r : | :d .t_1 |d .r :m ‖

Rests may be of any length, long or short. A half-pulse rest is indicated by a blank space on one or other side of the dividing dot. Thus, in the first half it will appear as

: .l |l .l : .l |l

in the second half as

|l .l :l . |l .l :l . ‖

Quarter rests are just as readily indicated to the eye. For example, we see at once that here

: ,l .l ,l | ,l .l ,l

the first quarter is silent, while here

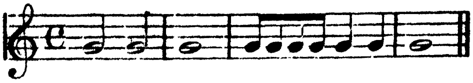
:l ,l .l , |l ,l .l ,

the silence is in the last quarter. Silent thirds may appear at first to be less clear. The following are the forms more generally met with :

First Third Silent .. .. .. : ‘l ‘l
Second Third Silent .. .. :l ‘ ‘l
Third Third Silent .. .. .. :l ‘l ‘
Second and Third Thirds Silent :l ‘ ‘

The whole matter of time-notation may seem, on first acquaintance, a little puzzling to the student. It is certainly much more original and novel than the notation of tune. But it is founded on a skilfully conceived and well thought out system, and the singer will soon discover that there is less difficulty in theoretically understanding the various subdivisions of the pulse than in giving practical effect to them by his voice.

One very important point has to be noted about the writing of Sol-fa time-notation. It was a point upon which Mr. Curwen laid great stress, and it is this, that each pulse in the same line of music must occupy exactly the same lateral space. Mr. Curwen would illustrate his meaning by showing how in the Staff notation this rule is disregarded, as, for example:



Here the measures and pulses fill very different spaces, according to the number of notes they contain. In Tonic Sol-fa they must be made equal, as thus:

|s :— |s :— |s :— |— :— |

|s .s :s .s |s :s |s :— |— :— ||

The pulses, to quote Mr. Curwen once more, are "measured out, like the inches on a yard measure, and the eye rapidly values the length. An experienced Sol-faist keeps time by judging the distance between the notes, only stopping occasionally to look at the accent marks; and when through bad printing the pulses are unequal, he is completely put out." In writing Tonic Sol-fa, then, see that the accent marks are equidistant, and that, moreover, the medium accent and the weak accent are of a size with the notes. The strong accent should be at least double the length of the medium. Here is a bad but common specimen of Sol-fa manuscript:

|d :m / r :d .m| s : l |t. l : s |

Should be written:

|d :m |r :d .m |s :l |t .l :s |

Practically, the Tonic Sol-fa notation is a notation which gives visual expression to tune and time. It sets down the notes of the scale in its own peculiar way, and it indicates the lengths of the notes, also in its peculiar way. Beyond that, it may be said to correspond with the Staff. Its signs for *staccato* and *legato*, for example, are the same. Thus, when a note has to be struck in a short, disconnected manner, it is marked above with a dot. If the *staccato* is to be crisp—very pronounced—a dash is used: in both cases just as in the Staff. "Holds," again, are common to both notations. The sign 𝄐 is familiar. It means that the note is to be "held" or prolonged at the will of the performer. Thus, a three-pulse *Doh* with a hold over it might be made to occupy the time of five pulses. The hold is of the nature of a rhythmical licence. Repetitions, again, are indicated, as in the Staff, by the use of "Da Capo," or "D.C.," meaning "return to the beginning," etc. In everything that relates to the expression of the music, to its manner of rendering as regards force and intensity, soft and loud, fast and slow, etc., the two notations make use of common terms. It would thus be superfluous to repeat the information given under this head in the Staff notation papers, which the Tonic Sol-fa student may consult with profit to himself. He will find in the glossary in part 1, page 42, a list of all the musical terms generally used for the direction of singer or player.

There is just one variation to be noted in this connection. In the Sol-fa notation the sign for the slur takes rather a different form from that used in the Staff. In the Staff, when two or more notes are to be sung to one syllable, a curved line is drawn over them. In Sol-fa, the plan is to draw a *straight* line *under*. So long as the line continues, only one word, or one syllable, as the case may be, is to be sung. Thus:

.s₁ |d :d |d,r.m,f :s .d |r :r .m,f |m

When Bri - tain first at heav'n's com - mand.

In the Tonic Sol-fa notation there are no signs of phrasing, as in the Staff.

When a change of key occurs there is never any doubt about it in the Sol-fa notation. Let it be premised that Sol-faists distinguish very sharply between transition and modulation. "Modulation," says the Staff theorist, "is the passing from one key to another." The term transition, he admits, "is also used, though principally to designate very brief modulations to keys not dwelt in." The Sol-faist, on the contrary, makes transition refer to all changes of key whatsoever, transient or of lengthened duration; while the term modulation he confines strictly to a change of *mode*—from major to minor, or *vice versa*. We will take transition first, the passing for the time being into a new key, where the old governing *Doh* gives up its place to a new *Doh* founded on a certain note of the old key. Before explaining how the notation expresses this, we had better clearly understand the nature of transition itself.

In a very short composition—a four-line hymn tune, for example—the composer may feel quite satisfied to remain in the one key throughout, though even in the shortest compositions transitions are often found. In a longer work the ear of the listener gladly welcomes, if it does not actually demand, a shifting of the *Doh* on to some other sound than that with which the piece began. In every instrument, as Mr. Curwen puts it, there is only a certain limited range of sounds at the composer's command, and he seeks to approach these from every point of view, to clothe them in every colour, and to make his changes as pleasantly striking as possible. Mr. Curwen insists that the pupil must be made, first of all, to *feel the need* of transition. This is easily possible by directing his attention to certain melodic factors of transition in which *Te* and *Fah*, the distinguishing notes of the scale, play the chief part. Look at this little bit of tune:

:d |m :– .m |r :d |f :f |m :r |

|m :s |s :f |s :— |— ||

Does not the ear instinctively feel that something is wrong about the next last note? The ear wants the *Fah* to be a "leading note" to *Soh*—feels, in short, that the *Fah* ought to be raised a semitone, so that these two notes shall sound like a new *Te Doh*. If we take it thus, then we have a simple transition where the *Soh* of the old key is turned into the *Doh* of the new key.

This is the commonest of all transitions. Next in frequency is the transition which makes the old *Fah* into the new *Doh*. The one is called the ***first sharp remove***; the other, the ***first flat remove***. The evolution of the process may be shown by taking our old Modulator for a centre, and writing a couple of little modulators by its side, the one having its *Doh* opposite the *Soh* of the centre modulator, the other having its *Doh* opposite the *Fah*.

d'	f'	
t	m'	l
l	r'	s
s	DOH'	f
	TE	m
f		
m	LAH	r
r	SOH	d
		t_1
d	FAH	
t_1	ME	l_1
l_1	RAY	s_1
s_1	DOH	f_1
	t_1	m_1
f_1		
m_1	l_1	r_1
r_1	s_1	d_1

Here we see at once an explanation of the terms "first sharp" and "first flat" remove. When the old *Soh* becomes the new *Doh*, the old *Fah* has to be sharpened (raised a "little step") in order to create a new *Te*. Similarly, when a *Doh* is set against the old *Fah*, the old *Te* has to be flattened (lowered a "little step"), that the new *Fah* may come rightly into place.

So much for what may be called the theory of transition. We are now prepared for an explanation of how transition is written. It is an exceedingly simple matter. When the transition is very short indeed, the new tone is written as a Chromatic note—*fe*, *ta*, etc., as the case may be. Thus, the last six notes of the above illustration might be written:

:r |m :s |s :fe |s :— |— ||

But even here, and at any rate in the case of all lengthened transitions, the "better method" is adopted of writing in the new key. The passing over into this new key is indicated by means of what is called, very appropriately, a "bridge-tone." A small note indicates the old key and the usual size of note the new. Thus, if the old *Soh* or the old *Fah* is to become the new *Doh*, the notation will show it in this way: ^{s}d ^{f}d

Our previous illustration would therefore be written as follows:

Key F. Key C.t.
:d |m :-.m |r :d |f :f |m :^{r}s |
|l :d' |d' :t |d' :— |— ||

The indication "Key C" shows the new key which is entered, and the "t" following it points out the name of the new sound not in the old key which it is necessary to introduce. Similarly, if we pass from the key of F to that of B flat, as here:

Key F. f.Key B♭.
:d |r :m |f :l |s :— |— :$^{d'}$s |
|f :m |r :d |t_1 :— |— ||

the "f" at the left side of the new key-name shows that *Fah* is the sound that was not in the old key. This pointing out of the new tone is entirely for the guidance of the singer's ear. And, indeed, in the letter notation, it is the singer's convenience that is consulted first. Thus, at the return to the former key, the bridge-tone is always placed at the point where it can most readily assist the singer, whether that corresponds with the actual theoretical change or not.

It is hardly necessary to say that transition is not always made to a key of one "remove" from the prevailing key. This fact the student can bring home to himself by constructing a modulator, not with one other modulator on each side, but with six or seven modulators on each side, each modulator in its turn taking the previous modulator's *Soh* or *Fah* and placing a *Doh* opposite it. Thus, having set down one modulator on the right side of the centre modulator by placing its *Doh* opposite the old *Soh*, he can deal similarly with the second modulator by placing a *Fah* opposite its *Doh*, and so creating a third modulator. A like process can be adopted for the left side. Each new modulator will represent a new key with a new tone not found in the modulator that preceded it. Well, we often come upon transitions in which the intermediate keys (modulators, let us say) are skipped over, so that the new key may require, not one, but three or four new scale-notes. A single example of this will suffice:

Key C. s.d.f. Key E♭.
|d' :— |t :-.d' |d' :— |— :$^{d'}$l |l :— |t :— |d' etc.

Here is a transition which passes over two keys. The original key, observe, is C. Thus, to reach E flat, we have to skip altogether the intermediate keys of F and B flat. More distant "removes" are much used in modern music, where the tonality has often a tendency to continual shifting.

Now we are in a position to take up the subject of modulation. Most people who know anything at all about music know that there is some distinction between the so-called major and minor modes. Briefly, a "mode" arises from the prominent use of one particular note in a composition. Thus, if a piece begins and ends with *Doh*, and all through has *Doh* as a sort of central pivot, it is said to be in the Major Mode. If, on the other hand, it takes *Lah* for its dominating note, it is said to be in the Minor Mode. The distinctive terms Major and Minor are derived in each case from the third above the dominating factor. The third above *Doh* (*me*) is Major, hence the mode which recognises *Doh* as its "governor" is a Major Mode. In the same way, the *Lah* mode is a Minor Mode, because the third above *Lah* (*doh*) is a minor third.

Formerly, they used to have modes founded on every note of the scale: national folk-songs still survive in the *Ray* and *Soh* modes. But in modern music only two modes—the Major Mode of *Doh* and the Minor Mode of *Lah*—are recognised. The old minor mode of *Lah* was simply the unaltered scale founded on that note:

l_1 t_1 d r m f s l

Thus, we have the Scottish air "John Anderson, my Jo" ending in this way:

:l_1 |m_1 :l_1 |l_1 :s_1 |l_1 :— ||

But the modern *Lah* mode is different. It is partly a concession to the exigencies of harmony, partly a concession to the modern ear, which had got so accustomed to the prevailing major mode, with its-half-tone (*te*) below the key-note, that it did not take kindly to a mode with a whole tone (*soh*) below its key-note. Hence, the *soh* was sharpened so as to make it a semitonic leading-note to *Lah*. The result was:

l_1 t_1 d r m f se l

the *se* taking the place of the old *soh*. But here a new difficulty presented itself. The leap from *Fah* to *Se*—a tone and a half—is by no means an agreeable progression; and so the *Fah* is often raised to make a smoother melodic interval. What shall we call this sharpened *Fah?* It will not do to call it *fe*, for *fe* suggests the first sharp key. So, in Sol-fa it is called *ba* (pronounced *bay*), and to save space is occasionally contracted to *b*. It is a note artificially introduced, remember, having no existence except in connection with *Se* in the minor mode. The final result, then, is this:

l_1 t_1 d r m ba se l

There are thus three forms of the minor scale; two of them diatonic (moving by tones and half-tones), but differing as to the place of the semitones; the third chromatic—that is, introducing chromatic intervals and containing three semitones.

The Sol-faist takes a very different view of the minor mode from the Staff notationist. The latter regards the minor mode as an independent, though "relative," scale; the Sol-faist, on the contrary, regards it as merely another form of the major scale—a "mode" of using the scale of *Doh*. Thus, while the Staff notationist speaks of the separate keys of C major and A minor, the Sol-faist looks upon them as practically one key; A minor, in his view, being merely a "mode" of C major. Hence, in giving the pitch-note of the key, the Sol-faist always places *Doh* first; so that when the Staff notationist says "A minor," the Sol-faist says "Key C, *Lah* is A." In short, the Sol-faist gives the pitch of both *Doh* and *Lah*. To a beginner, the whole subject of the minor scale or mode presents very considerable difficulties; in Sol-fa the difficulties are perhaps rather less than in the Staff. In either case they are theoretical rather than practical.

Mention has been made of "chromatics." These are practically the equivalents of the accidental sharps and flats of the Staff. Composers, says Mr. Curwen, often use an effect which is derived from the pleasure that the ear takes in transition. They introduce a *fe* or *ta*, or some other note which leads us to expect a transition, and instead of changing the key, they contradict their intention and remain in the original key. If *fe* is the new tone in a "sharp" transition, it is manifest that if *fah* follows it immediately the old key is reaffirmed, and *fe* blotted out. So when *ta* is the distinguishing note, if we pass on to *te* we reassert the old key. This treatment is called "chromatic," to distinguish it from "transitional," though it must be observed that there are chromatics which do not necessarily even suggest a change of key.

In the Sol-fa notation the names for the sharpened and flattened notes of the scale are shown here, first in ascending, and then in descending:

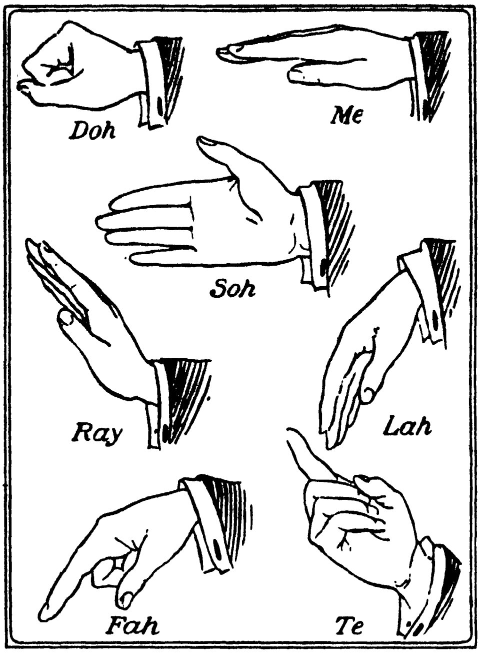
d de r re m f fe s se l le t d'

d' t ta l la s fe f m ma r ra d

It is necessary, of course, to write these chromatic notes in full, so as to distinguish them from the corresponding diatonic note.

Thus far we have dealt with Tonic Sol-fa chiefly as a notation. But it is much more than that. Sol-fa has a *method of teaching* which is, in several respects, peculiar to itself. For instance, great stress is laid on the mental or emotional effects of the individual notes of the scale. *Doh* is recognised as firm and bold; *Soh* as bright and trumpet-like; *Me* as calm and restful; *Lah* as sorrowful and wailing; *Fah* as desolate and awe-inspiring; *Ray* as rousing; and *Te* as shrill and piercing. Great pains are taken by Sol-fa instructors to impress these emotional effects on the minds of pupils, and practical experiment is every day proving that their recognition is a very great help to the correct singing of the notes. Of course, the effects described apply strictly only when the notes of the scale are sung or played slowly. A quickly moving rhythm and certain forms of accompanying harmony may each greatly modify the individual effects. Thus, the minor mode, which sounds sad and solemn in a measured movement, may be made to sound quaint and jovial when sung rapidly.

Out of these mental effects may be said to arise another special feature of Sol-fa teaching—namely, the use of manual signs for the various notes of the scale. Thus, every manual sign endeavours to suggest the emotional characteristic of the tone for which it stands. The clenched fist typifies the firmness of *Doh;* the restfulness of *Me* is indicated by the flat palm; the rousing character of *Ray* by the raised



MANUAL SIGNS

palm; and so on. These signs, which we here reproduce by permission of Messrs. Curwen & Sons, are much used in popular classes, either when the teacher desires to remind his pupils of the mental effects just described, or in voice exercises, when it is desirable that the singer's attention should not be distracted by having to look at book or modulator. A system of manual time-signs is much less used.

A third-feature of Sol-fa teaching is the separate study of tune and time. Tune is taught first from the modulator, and then time is taught by itself, largely by means of a set of "time-names," the improved invention of a Frenchman, M. Aimé Paris. It would occupy a great deal of space to give a complete list of these time-names, with the corresponding notation. The following illustration introduces the rhythmical forms most frequently met with:

d :m	s :—	s .m :l .d'	s :—
Taa Taa	Taa - aa	Taa Tai Taa Tai	Taa - aa
m :– .f	r :d,t,.d,r	m :	
Taa - aa tai	Taa ta fa te fe	Taa Saa	
s :m	d',s.m :d ,m.s	d :— ‖	
Taa Taa	Ta fa Tai ta fa Tai	Taa - aa	

In applying these names to his early exercises, the Sol-fa pupil sings them *on one tone* till he has mastered the time, and only then does he try to combine the time with the tune. The value of the method for beginners is obvious. It gives them a confidence which they could not possibly acquire so soon in any other way.

Much more might be said about the Sol-fa method of teaching if one had "ample room and verge enough." Mr. Curwen has admirably summed it up in a few words: "To let the easy come before the difficult; to introduce the real and concrete before the ideal or abstract; to teach the elemental before the compound, and do one thing at a time; to introduce, both for explanation and practice, the common before the uncommon; to teach the thing before the sign, and when the thing is apprehended attach to it a distinct sign; to let each step, as far as possible, rise out of that which goes before, and lead up to that which comes after; and lastly, to call in the understanding to assist the skill at every step." These principles find their most exhaustive explanation in "The Teacher's Manual of the Tonic Sol-fa Method."

In studying *harmony* [see THEORY OF MUSIC] the Sol-faist uses a chord-naming notation of his own. In the Staff the chords are indicated by a system of figured basses. In Sol-fa the nomenclature corresponds in simplicity with the notation of tune. Each chord of the scale is named by its Sol-fa initial letter, printed as a capital, as here:

m	r	d	r	m	
s	t	l	l	l	
d	s	f	f	d	
d	s	f	r	l	
D	S	F	R	L	etc.

In the minor mode the chord capitals are printed in italics. Chords in their direct form—that is, with the root in the bass, are said to be in the *a* position, but in the nomenclature the *a* is always omitted. The further positions (inversions) are indicated by the letters *b, c, d,* etc., as the case may be. Thus:

d	m	s	r	
s	s	r	t	
d	d	s	s	
m	s	t	r	
Db	*Dc*	*Sb*	*Sc*	etc.

The minor dominant chord—m, se, m, t—is known as ^{se}M. When a seventh, a ninth, or a fourth is added to a chord (remember that a common chord consists of root, third and fifth), the fact is indicated by a little figure at the upper left-hand side of the chord-name:

^7S ^4S ^9S etc.

Passing notes, again, are indicated by an italic *p* printed under the chord-name—*p* only when the passing note is dissonant, *cp* when consonant.

Such are the general principles of the Sol-fa notation and method of teaching. For minute details it is necessary to consult the published manuals and treatises of the Tonic Sol-fa Press, in particular "The Standard Course of Lessons and Exercises in the Tonic Sol-fa Method of Teaching Music." The Staff notation musician who desires to study the notation in comparison with and from the special point of view of his own notation should see "Tonic Sol-fa," by John Curwen, in Novello's "Music Primers" series.

CYCLOPÆDIA OF SHOPKEEPING

BABY-CARRIAGE DEALERS. The Buying, Stocking, Selling, Hiring, and Repairing of Baby Carriages. Profits of the Trade.

BABY-LINEN OUTFITTERS. The Capital necessary, and the Method of Spending it. The Shop and its Accessories.

BAG AND TRUNK DEALERS. The Shop-Fittings and Stock. Details of Purchasing. Profits.

BAKERS AND CONFECTIONERS. Technical Instruction. Bakehouse Plant and Fittings. The Shop and its Requirements.

BABY-CARRIAGE DEALERS

The vendor of baby-carriages seldom confines himself to their sale. Occasionally they may constitute the backbone of a business, but more often they are merely a branch of a more important trade, such as that of the ironmonger, the house furnisher, the cycle or sewing machine agent, or the draper. As the trade, under British climatic conditions, is strictly a season one, the vendor of baby-carriages pure and simple finds nothing to occupy him during the winter months, so that his profits and turnover during the selling season must be fairly large to permit successful trading upon such a basis. There are some classes of shops with which the sale of baby-carriages goes well—as, for instance, that of a domestic laundry machine depôt, which has its busiest period during the winter months. The summer trade in baby-carriages equalises business somewhat. On the other hand, it is an awkward adjunct to the business of a cycle agent, as both departments are under pressure and both dead during the same months of the year.

Stock and Stocking. The stock takes up a good deal of room, hence the trade can be conducted properly only by the shopkeeper who possesses the necessary accommodation. The small ironmonger or draper whose shop and warehouse are closely packed with goods more necessary to his proper business should leave the selling of baby-carriages alone. The articles deteriorate easily from the scratching inevitable when they are mingled with miscellaneous merchandise, and this takes all the gilt off the gingerbread.

The sum of £50 will put in a very good stock of baby-carriages, and less than half of this sum will suffice if it be merely a department of another business. The dealers usually order season's stock in February, receiving delivery some time in March, and selling begins shortly before Easter. A good and well-assorted display should be made at the opening of the selling season, but great care should be exercised in repeating stock when it is sold, as very little is done after August. A few carriages may be sold in September, but from October to March the articles may be packed away out of sight. A shop with an open window is the best for the dealer. It permits street passengers to see the assortment, and the parents—especially if baby be the firstborn—are most particular in their choice.

Fashion. Fashion must be studied, especially by the man new to the business. It is rather easy to put in unsaleable or slow stock. Above all, expensive carriages should be ordered sparingly. The cheap article is that in which the bulk of the trade is done. The last few years have witnessed a wave of popularity for the light, collapsible baby-vehicle, termed the go-cart, or push-cart. This is not good for the infant occupant, and bad for the trade. It will not accommodate the infant in a lying posture, and it is not desirable that a very young child should sit erect for hours. Also, this type of baby-carriage is not more than half the price of the larger article, and therefore carries only half the profit. The dealer should always point out the disadvantages of the go-cart in comparison with the larger bassinette, or perambulator. If he makes a practice of doing so, he will probably succeed in selling the more expensive vechicle in every other instance. Go-carts may be retailed as cheaply as 10s., but the usual selling price is from 15s. to 25s., showing a profit upon selling price of 33⅓ per cent., or a little more. This type of vehicle is in diminished favour, but it will always have a certain acceptance by the flat dweller, who finds every square inch of house-room a matter of consideration, and by the parent who migrates to the seaside. The latter may transport it thither, and thereby save the expense of hiring a baby-carriage during the holiday.

Bassinettes. The bassinette, properly so-called, is a child's vehicle with a basket body, although the word is usually made more comprehensive. Bassinettes proper came into fashion a few years ago, and are gaining in popularity. The bodies were originally all imported from America and Canada, but English cane-workers have taken up the trade, and now very few bodies are of foreign manufacture. Bassinettes are usually more expensive than those with wooden bodies. We have seen them retailed at 35s. by cutting drapers, but the articles had the poorest bodies possible to mount on wheels. The mail-cart form of baby-carriage is also made extensively with a basket body, but the trade is not so great as it is in the larger vehicle.

Prices. Makers' lists are usually subject to 50 per cent. discount, although a few firms, chiefly high-class manufacturers, frame list prices upon a more moderate scale, allowing correspondingly smaller discounts. Also, 5 per cent. extra may be secured for cash payments, which should always be taken, even if difficulty be found in paying promptly. The large discount does not mean that the dealer secures

50 per cent. profit. He has usually to allow fair discounts to the purchaser, up to 20 per cent. Still, the profits possible are good. When drapers take up and push the department they usually play havoc with profits of more legitimate traders in their neighbourhood, but very frequently the draper sells only very cheap stuff, leaving the better trade to others.

A fair proportion of the trade in baby carriages is a cash trade, yet payment by instalments is becoming every year more common. But the trade wisely refuses to admit purchasers of low-priced goods to the advantages of gradual payments, for the simple reason that such goods might be worn out before full payment had been made. Full list prices, bearing the profit of 50 per cent., should be secured on all instalment business, and even so it does not pay exceedingly well. It demands the careful watching of each individual account.

Other Departments. A natural branch of a baby-carriage department is the selling of baby-chairs. There is always a steady demand for those of the three position type, of which Plant's patent was the pioneer. They yield profits similar to baby-carriages. Rocking-horses and children's toys are also frequently added, and should always be so if baby-carriages be the main department, as toys form a good winter trade, especially at Christmas-time. Bath-chairs also usually fall to the baby-carriage dealer, but their sale is exceedingly limited, except in watering-places, and it may be well to avoid stock.

Selling. The dealer who makes baby-carriages a prominent department should strain every effort to be looked upon in his neighbourhood as the leading man for such goods. The trade is particularly susceptible to influence by advertisement in the local newspapers. We have known excellent results attained by the practice of posting a neat price list and circular to the addresses given in the birth columns of the local press.

Repairing. The repairing of baby-carriages is not an extensive trade, but it is exceedingly remunerative. The stock necessary for its prosecution is not large—an assortment of indiarubber tyres, a few brass axle-caps, and some handles, being almost all that is necessary. Tyre-fitting pays well. The rubber tyres may cost not more than 10d. per pound, and a charge of 5s. or 6s. for fitting four wheels with new tyres will show a profit of half the price, even allowing for the labour of fixing. A new form of tyre with a wire centre has the double advantage that it is bought in coil, so that an assortment of sizes need not be kept, also that it may be fixed without heat, thus avoiding injury to the painted rims. When baby-carriage repairs include painting or upholstering, they have usually to be sent to other tradesmen to be done, as the dealer is seldom sufficiently expert in either work. In such cases smaller profits must serve—say, 25 per cent. upon the total charge.

Hiring. The hiring of children's vehicles is common, especially in summer resorts. It is remunerative, but charges vary, so that no general estimate can be given. Perhaps 2s. 6d. to 5s. per week may be accepted as an average price for an article costing 40s. to 50s. Hiring charges should be framed so that the cost price of the article is recovered by a season's hiring of, say, four months.

BABY-LINEN OUTFITTERS

A Woman's Sphere. The vending of baby-clothes is essentially a woman's occupation. It has many attractions for womankind, and especially for those who have known the joys of motherhood. It is an ideal occupation for a widow with only a small capital, and if she has any business ability, it can be made not only the means of a livelihood, but even of securing a competency. Many married women with business aspirations start a baby-linen shop in order to augment the income of a delicate or otherwise unfortunate husband, and the woman with tact, taste, and ability "to use her hands," invariably succeeds.

Capital and Shop. With a sum of £100 to £150 in hand, a fairly advantageous start may be made, the neighbourhood selected being, for preference, a popular residential one. A main street is not essential, unless the adventuress has ambitions beyond a merely family business. The trade is primarily a personal one, and a suitable shop should be chosen in a neighbourhood where mothers and children abound. The shop need not be large; in fact, it should be small, with living-rooms attached, nicely painted, and kept scrupulously clean and neat. The fittings should include a counter with a glass top (many of which may be picked up secondhand for about £5), several dummies of children at various ages, a few brass uprights of different lengths for displaying bonnets, hoods, cloaks, etc., and a brass stand with glass shelves. One side of the shop might be fitted with wood shelving for the various articles that come in, and to carry cardboard, millboard, and cloth-covered boxes of useful sizes, that are necessary for stocking small goods. A large mirror should also be provided. The window should have upright fittings, with brass movable arms projecting on either side. A sum of £15 ought to cover the cost of the entire fittings.

The Stock. The requirements for a baby-linen business are, broadly, all the articles of apparel necessary for a child from the moment of its birth until it is three or four years old. First of all, there is the layette. This includes infants' shirts, long day flannels, night flannels, longcloth petticoats, daygowns, nightgowns, woven cotton swathes, flannel swathes, diapers, Turkish squares, flannel squares, woollen boots, robes, cloaks, and hoods. The next—technically known as the "shortening"—stage is provided for by a supply of short frocks (made of nainsook, India twill, silk, or cashmere), bibs, cambric or longcloth slips, pelisses (in serge, piqué, or marcella—plain, trimmed, and embroidered), pinafores (nainsook and lawn), white and coloured wool socks and bootakins, and infantees (or fingerless gloves) in Lisle thread, silk or wool. For older children provision must be made by an assortment of walking-costumes, sleeping-suits, knickers, spencers, overalls, and gaiters of cloth and wool, not forgetting petticoats, chemises, and nightdresses.

An Opening Selection. One advantage this business has over general drapery is in the fact that there is no variety in sizes. The garments are mostly all of one size, and a beginner who is wise will not have a great variety of any one article. To the inexperienced every help is given by the wholesale baby-linen houses, any one of which will supply a complete assortment to suit all classes. It is not advisable, however, to leave matters entirely in the hands of the wholesale house. The endeavour should be to work as much as possible on sample lines at first, gradually increasing the stock as the business grows. The clever woman will make her stock as much as possible at home. At any rate, she should cut out and plan herself, and in these days of universal sewing machines the work can be run together by an assistant. She should buy pieces of flannel, nainsook, or longcloth, and cut them up to the best advantage. Therefore, with the majority of articles, the opening order should be for one sample of each, unless, of course, in the case of cheap things, such as swathes, woollen boots, diapers, and so forth, several of which are required at once by each customer. About £5 would be spent on a variety of robes and monthly gowns, and a similar sum on nightdresses and flannels. With such things the best way is to buy six quarter dozens at three different prices, varied according to the class of business. A stock of daygowns would cost £2, of hoods £2 10s., and with another £10 a fine assortment of miscellaneous articles, like slips, swathes, etc., could be obtained. In shortening goods, £5 would be expended on dresses, white and coloured; £2 on pinafores; another £2 on gaiters, stay-bands, petticoats, &c.; £5 on hats and bonnets, and £2 on bibs, spencers, and sleeping suits.

Accessories. There are many little things incidental to the business upon which we have not yet touched. These all tend to swell the profits; they cost little and look imposing. First may be mentioned macintosh goods, such as aprons for the nurse, accouchment sheets, diapers for the mother, sponge-bags, and pilches. An outlay of another £2 on these, and two bassinettes—one trimmed and one not—would cost another £2. A toilet-basket trimmed, and another untrimmed, would not come to more than £1, while a selection of trays, dotted here and there in the shop, with puff-boxes (including a loose selection of powder-puffs and violet powder), babies' hairbrushes and small combs, costs little money, looks well, and generally draws the purchasing parent. The hairbrushes, puff-boxes, etc., are made of pearl, ivory, celluloid or bone. Then, baby-linen and ladies' underwear invariably go together in the big drapery houses, but the beginner would not be able to launch out strongly in that direction at first. However, it might be found expedient to spend £15 on nightdresses, chemises, camisoles, and combinations for young girls and ladies, and by-and-by these might be augumented by a select assortment of dainty underskirts, knickers, nightgowns, corsets, dressing-gowns, and tea-gowns. Taste and neatness in window and in internal shop display is necessary. The window should be lightly dressed, with not too many articles displayed, and it should be dressed daily. A few of the dummy children arrayed in all their glory are usually placed at the back. Hoods, dresses, and coats could be dotted here and there about the shop on the stands aforementioned.

The Question of Profits. Drapers generally concede that baby-linen is one of their best paying departments. Experience in drapery is a help but not an actual necessity to make a success as a baby-linen vendor pure and simple. Provided the woman who essays to make a living at the trade has a fairly level business head, an average profit of from 33⅓ to 40 per cent. is possible. A bonnet selling at 3s. 11d. would probably cost 2s. 6d.; pelisses costing 3s. 3d. sell at 4s. 11d. Towelling at 3s. per dozen, on the other hand, would perhaps have to be sold at 3s. 11d.; but, taken all in all, the profits are as stated. It must not be forgotten, either, that a woman "handy with her fingers" can make many things, such as babies' bonnets and dresses out of next to nothing, and thus swell the total profit. A smart woman will turn over her stock six times a year. Her expenses in a small shop such as we have sketched (rent, £40; rates, £10; gas, £10; and errand boy or girl, £20) would be about £80, so that if she started with £80 stock, turned it over six times a year and made an average profit of 33⅓ per cent., she would be £80 in hand at the end of the year. This is calculating on good, straightforward trading, but the beginner whose net profit at the end of the first few years does not come up to that sum, or even the half of it, need not necessarily be discouraged. The same buying terms and credits apply to this as to the drapery trade.

BAG AND TRUNK DEALERS

In large cities the selling of bags, portmanteaux, and trunks may be a special business, but in smaller towns the trade is usually allied to the ironmongery, drapery, or house furnishing trades. We may consider first the capital and equipment necessary for a distinct bag and trunk dealer in a prominent city thoroughfare.

Premises and Fittings. The shop must be fairly large, as the stock is bulky, and a first-class trade in London demands premises with a rental of £350 to £500 a year. The fittings are expensive items. They must be good and up-to-date. The front window ought to be enclosed and dustproof, with plenty of movable glass shelves and brackets. Its cost would be about £25. The side farther from the door may be fitted with a large plate-glass mirror. A large wall-case about 6 ft. high is a desirable part of the equipment, and should also have a silvered glass back. The cost of this would be about £30, but if this sum be considered too heavy a charge, black paper may be used for backing. It is the material next best for showing up the goods displayed. Then £25 might well be spent upon a counter-case with glass sides and ends, with plate-glass top, and with movable glass shelves. All woodwork should be black, for the reason already given. The shelves may be of deal, painted black. For trunks, suitable racks may be made of ordinary gas tubes—say, three rows of two pipes, supported by wooden uprights, provided with holes to allow the horizontal tubes to be changed as required. The ceiling whitened and the walls washed in a blue-grey colour, plain linoleum over the entire floor, a few good rugs, and six black bent-wood chairs will complete the decoration and the fittings, at a total cost of about £100. Electric light is the best illuminant, as it allows the goods and the shop to remain fresh longer than gas, but the latter should be laid on for emergency use.

Capital and Staff. The trader beginning in the manner we suggest must have not less than £500 capital. Our scheme of fittings and decoration has left him rather less than £400 for stock, not a penny too much. Wholesale merchants or manufacturers will, if they know their man, accommodate him by giving three months' credit and allowing full cash discount. Even so, it may be necessary to grant bills for part of the stock account, especially if business moves somewhat slowly at first, but it is better to mortgage the future thus than to deplete entirely the bank balance, because rent, taxes, and current expenses are steady periodical charges which may not wait for settlement.

The only shop assistance required by the beginner would be a boy fresh from school, at 5s. or 6s. a week, and a porter at 20s. a week to do packing and unpacking, cleaning and sweeping, and to carry home purchases.

Profit. The profits in the trade are good, seldom less than 33⅓ per cent. upon turnover, which means 50 per cent. upon invoice prices. More may often be had. Gladstone bags costing 7d. or 7½d. an inch may be sold for 11d. or 1s. an inch, and as stock can usually be replaced quickly, it may be turned over three or four times a year.

In the larger articles of sale fashion does not change much, and the stock is not apt to become soiled, hence there is little loss by depreciation. In fact, a trunk or a leather bag that has lost its pristine freshness without having become damaged is often preferred by the purchaser.

Bags. Besides kit-bags, square bags, gladstone bags, and brief-bags, stock must be kept of many varieties that come under the general heading " bags." Small fancy bags for ladies' shopping are in good demand. Bags to hang from the waist, from the plain 1s. article to artistic patterns in coloured leathers, are also much sold, especially when shown, as they make acceptable presents. They must be stocked in many colours, to match the dresses of the wearers, and retail as high as 50s. each. Courier, brief and square bags, gladstone and kit bags, should be in a nice nut shade of brown cowhide, and it is well to show them in sets ranging from the smallest to the largest. All may be kept in three qualities, the best lined with leather, tan-coloured for preference. Black leather bags have a very limited sale, and the stock of them should be small.

Fitted Bags. Fitted bags for ladies should be stocked from 21s. upwards. The cheaper qualities are usually in black roan leather, and the better varieties, from 63s. upwards, in tan hide, lined with red leather, and fitted with ebony brushes and silver-topped bottles. A special line is often made of ladies' fitted bags, at 5 guineas, in varieties leather lined with watered silk to match, or to contrast with the outside. At higher prices—say, 7, 8, and 10 guineas each—one of each kind will suffice for stock. Large, cumbersome bags are not now wanted. The usual sizes are 12, 14, and 16 in., with the 14 in. in greater demand. Fitted bags, combined for man and wife, may also be kept, although they sell in smaller quantities than those mentioned. Suit cases, fitted bags for gentlemen, and " Saturday to Monday " bags are also necessary in several varieties and qualities similar to the stock of ladies' fitted bags. By purchasing the fittings direct from the makers and not from the manufacturer of the bags quite 10 per cent. may be saved, and the fittings may be arranged to the individual taste of the seller, who may thus always have something different from the articles being sold by his competitors.

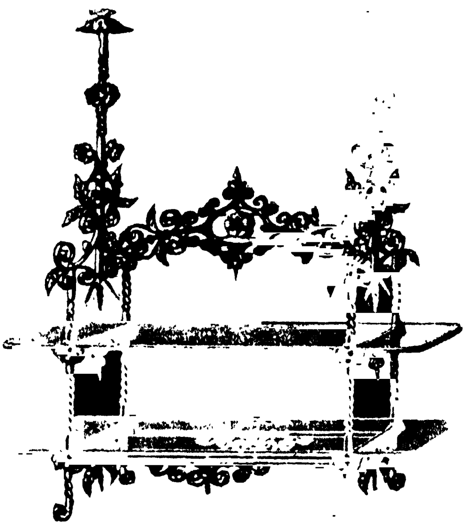
Small holdalls for ladies' use, 24 in. wide, to sell at 5s , 27 in. at 5s 9d., 30 in., 7s. 6d., should be a cut line, and be made of smart tweeds, with brown leather bindings, straps and handles. Better patterns, to sell at 10s. 6d., and larger sizes at about 21s., for gentlemen's and family use, should also be in stock.

Other wares necessary for stock include dressing-cases for both ladies and gentlemen—the cheaper qualities bought direct from Germany, and the better made up, similar to the fitted bags already described; dress-baskets, in sizes from 24 to 36 in., selling at 1s. to 1s. 6d. per inch; shallow dress-baskets, in two sizes, 39 and 42 in.; gentlemen's hat-boxes, from the light basil article, retailing at 12s. 6d., to the light-weight solid leather variety, with places for straw, bowler, and silk hats; bonnet boxes in good variety, from the cheap design covered with American cloth, and selling at 3s. 6d. to 7s. 6d., to the leather-bound style, with four and six wire cones, retailing at 12s. 6d. and 21s. respectively; holdalls and rug-straps; and, finally, gun-cases, cartridge-cases, and game-bags.

Small Wares. In the smaller articles, all of which are remunerative, purses are the most important. They have a steady sale. The humble shilling article must not be neglected, as it is a favourite. Prices range up to 30s., at which figure they should be mounted with 9-ct. gold. Most purses are of foreign manufacture—the cheap, useful kind, German; the best, Austrian, from Vienna; only the pigskin and some others, in which strength and not elegance is the prominent feature, are made in England.

Letter and card cases, cigar and cigarette cases are always in request for presents, and just before Christmas-time stock should be heavy, as delay in having orders for new stock fulfilled is common. The favourite price for a letter-case is 2s. 6d.; for a card-case, 1s.; for a cigar-case, 2s. 6d.; and for a cigarette-case, 1s. 6d. The better qualities should be kept in such leathers as long-grain Morocco, shark, lizard, and sealskin, elephant, and crocodile. The favourite leather is golden crocodile, either dull or polished. The additions of monograms to these goods is remunerative. Other articles in this department include dog-leads, collars, and whips, whistles, watch bracelets, collar, tie, stud, and jewel boxes; leather luggage labels; tourist, writing, and music cases and portfolios.

Trunks. Most dealers in leather goods whose stocks we have been reviewing leave to the ironmonger the sale of steel trunks, holding them to be out of place among the leather goods. This can be done without much regret, as they are less remunerative than the goods which the bag and trunk dealer handles. Steamer trunks are an important item. The length may be from 30 to 42 in., but the height should not exceed 14 in., as this is the limit allowed by some steamship companies. The best varieties are made of compressed cane, but this material is finding a serious rival at little more than one-third the price since the introduction of trunks of three-ply wood. Steamer trunks are not usually sold fitted with a tray, but customers appreciate the convenience of this accessory, and the trader who carries stock so fitted is well advised. Many other styles of steamer trunks are made, the cheaper being of wood covered with canvas and strapped. Overland and imperial trunks are made, and must be stocked, in similar variety to steamer trunks, including the P. & O., Orient, and troopship regulation size trunk. If in London, samples of bullock and transport trunks may also be held.



1. ARTISTIC WINDOW FITTING

Added Departments. We have indicated briefly the nature of the stock of a general bag and trunk merchant who would hold a representative assortment of the goods he professes to handle. As business grows, and as funds permit, he may add other wares—such as small silver and ivory articles, nicknacks, clocks, thermometers, games, and playing-cards, sundries usually associated with the stationery trade, such as fountain and stylographic pens, gold and silver pencil-cases, letter balances, and photo frames, especially those for the pocket; also fans, flasks, picnic and tea baskets, walking-sticks, and other objects suitable for presentation. Articles which naturally fall in with the trade are fittings for bags, such as combs and brushes, razors, pocket-knives, and scissors.

Repairs. The repairing department may be made exceedingly profitable, and, if possible, a man should be retained on the premises to execute the work, promptness being usually the essence of any repair job. Initials should be stamped on all leather goods bought, and painted on trunks, without charge. If stock of silver letters be kept for finer articles, they may be fixed while the purchaser waits. They may be bought at 3s. a dozen, and sold at 6d. each. Larger ones cost 6s. a dozen, and sell at 1s. each. Silver monograms may be bought for 1s. 6d., and sold at 2s. 6d.

Terms of Selling. From its nature this trade is principally of a cash description, as the chief customers are travellers, many of them *en voyage*. Credit must, however, be given sometimes to residents in the neighbourhood. Some months bring much business, and some are very quiet. The best time of the year for London dealers is from August to October. The starter should open shop in June, as he may thus take early advantage of the busy time.

As a Side Line. We have depicted the bag and trunk merchant who begins business in a good street in a large city. In a smaller city articles of a cheaper class than many we have described are more suitable. There are always specific factors which no general article can take into calculation. The ironmonger, draper, saddler, or other tradesman, who would embark in the selling of bags and trunks as a side line, would do well to invest capital only in such goods as steamer, overland, and imperial trunks, gladstone, square kit, and brief bags, holdalls and rug-straps, and enlarge his scope as he gains experience. He should always have on hand priced catalogues, showing particulars of the other articles we have mentioned, in order not to lose the opportunity of selling from the list should occasion offer.

BAKERS AND CONFECTIONERS

The business of a baker is essentially one where manufacturing skill and commercial ability must go hand in hand to the attainment of success. An average degree of both qualities will yield better results than an excess of the one and a conspicuous lack of the other. The man whose knowledge of the art of baking enables him to excel on the practical side will fall far short of high success unless he unites with this practical ability the commercial ability to adjust expense to output, to market his products efficiently, and to see that the profit-sucking leeches of waste in manufacture, distribution, and the collection of accounts finds as small a hold as possible upon the organism of his enterprise. Many of the cautions necessary for observance by the successful baker are those essential in any department of commercial activity, and it is not our intention to put stress upon them here; but for the discussion of the requirements peculiarly pertaining to the baker and confectioner this is the fitting place.

Scientific Baking. The establishment of baking upon the scientific basis which is becoming more and more the foundation on which the fabric of the industry rests in this country may be said to date from the Healtheries Exhibition, held in London in the year 1884. At that function attention was first prominently drawn to the possibilities of machinery in bakehouse economy, and, like yeast in the dough, a ferment of unrest began to operate in the trade corpus, requiring for its satisfaction the introduction of the best baking plant which engineering skill and an appreciation of the ends to be attained made possible. Then one could see on all sides bakers' shops with the legend "Model Bakery" or "Steam Bakery," indicating that precedent had been neglected and modern scientific methods introduced. These signs are to be seen less frequently now. Establishments where they might be exhibited have become almost the rule, not the exception.

2. INTERIOR OF BAKER'S AND CONFECTIONER'S SHOP

Technical Education. The first essential to a successful baker is a knowledge of baking. Such a statement may seem to be entirely gratuitous and superfluous, but it is not so. By a knowledge of baking is meant not merely the experience gained by years of practice between the dough trough and the oven, and an acquaintance with only the mechanical side of the business, but the much higher skill in which science is wedded to practice and the reasons for processes are understood as well as their manifestations. The scientific side of baking is receiving attention as never before. The National Association of Master Bakers and Confectioners has co-operated with the Borough Polytechnic Institute in the Borough, London, S.E., and they have spent thousands of pounds sterling in facilities where the rank and file of the trade may acquire a thorough technical knowledge of bread-making. In the institution mentioned there is the only permanent college of baking in the United Kingdom, and every aspirant to success in the business of baking should take advantage of the opportunities offered. There are two large bakeries, equipped with modern machinery and appliances, and practical instruction in both bread-making and confectionery is conveyed. Other subjects which may be studied under competent professors include chemistry, physics, biology, and drawing and modelling, all in their relation to the manufacture of bread and confectionery. The school session lasts from September to May. The most rapid progress is to be secured by attending the day classes, held between the hours of 9 a.m. and 4 p.m. It is found that day students are recruited almost exclusively from the sons of master bakers. For those whose vocation compels them to be employed during the daytime, evening classes are available on two days a week for each subject. Both classes of students must sit for the official examinations held by the City and Guilds of London Institute in conjunction with the National Association. The class fees for day students are £6 6s. per session and for evening scholars 7s. 6d. for an elementary course and 10s. 6d. for an advanced course in either class.

Provincial Instruction. The undoubted success of the National School of Baking and Confectionery in London has inspired provincial centres with the ambition to offer similar facilities for the study of the art of bread-making. The sum of about £5,000 has been raised to found a school of baking and confectionery in connection with the Glasgow and West of Scotland Technical College. The institution of the school has not yet been accomplished, but it cannot be long delayed. Evening classes, confined to those engaged in the baking trade, are held in many provincial towns, including Manchester, Belfast, Hull, Liverpool, Bristol, Ayr, Hamilton, Kilmarnock, and Glasgow. In addition to these the professors at the National School visit selected towns during the summer months, secure a bakehouse and open classes for bakers in the district. The session at these summer classes lasts usually from 5 to 8 weeks, with two days' instruction in each week. Thus, while some towns are more favoured than others in the opportunities for bakers to receive instruction in the science of their craft, the agencies are fairly well distributed, and scarcely a baker in the country would be unable to take advantage of one or other of them if the desire were keen.

The Bakehouse. This is not the place for any technical digest of the principles of bread-making, which will be treated in another part of the SELF-EDUCATOR. The commercial side of the business only lies within our province, and in reviewing the baker's equipment we shall begin with the bakehouse. The technically-instructed tradesman naturally wishes to instal the appliances which will give scope to his scientific knowledge, and assuming that he must study economy in his disbursements he may be recommended to invest in an outfit of the following details.

1 Peel oven.
1 Flour-sifting machine.
1 Dough-mixing and kneading machine.
1 Gauging and tempering cistern.

3. CONFECTIONERY DISPLAY STAND

These items will cost him about £150, in addition to which he must bear the cost of preparing the brick foundation and chimney for the oven, unless, indeed, he is fortunate enough to secure as a bakehouse a building in which these are already fitted. Some bakers' outfitters are willing to quote for, and undertake, the whole installation, including any necessary bricklaying, and it is often the wiser course to allow them to do so. A permanent oven built in the usual manner becomes, of course, a landlord's fixture, and the tenant can neither remove it nor demand any consideration for it upon the expiry of his lease. Should the tenant, however, take the precaution to have one layer of timber placed below the oven, but over the foundations, he will thereby reserve to himself the liberty to remove the oven whenever he may wish, as this provision prevents the structure from being considered a permanent fixture.

4. SHOP-RACK FOR SMALLS

The wisdom of acting in this way does not lie in the value that would attach to the oven, should he decide to remove it, but in making the landlord less liable to seek to increase the rent upon any renewal of the letting term.

The baker may save £50 of the outlay suggested above, if he will content himself with a portable oven, but unless there are stringent reasons for so doing he will be wise to give the larger sum for the more permanent article. His sundries, including two dough-tables, a dough-trough, a bread-rack and a complete equipment of utensils will increase the bill by £25.

Some expenditure will be occasioned by the confectionery department, into which, it may be assumed, our baker will also venture. A sponge-whisk will cost about 21s., and a full assortment of tins, moulds, pipes, and all the necessary utensils may be put in at a cost of from £10 to £12.

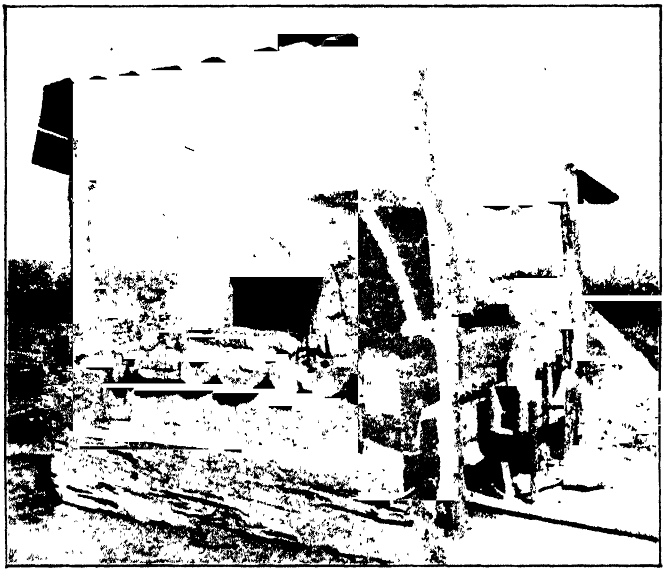
A small power whisk would cost £3 3s., and a cake machine £20, but these would be an unnecessary expense until the confectionery trade had developed very much indeed.

Output. A plant such as we have sketched will permit an output of 15 to 20 sacks of flour per week, including £6 worth of smalls and confectionery. Even 25 sacks might be put through, but this would be difficult, and could scarcely be maintained. The limit is reached, not by the machinery, but by the oven. The machines we have mentioned could be worked up to the baking capacity of two ovens, hence, doubling the capacity does not double the cost of the equipment. This is a detail which illustrates how the larger producer can often compete against the smaller man upon more favourable conditions.

Assistance. We have assumed that our baker commencing business is to be his own chief workman. There is small chance of success otherwise. An enterprise on such a scale would be unable to support a proprietor who did not earn a workman's wage by labour in his own bakehouse or by delivering his bread. He would want a man, whose wages would depend upon locality. London bakers earn 25s. to 30s. per week; bakers in the English provinces 24s. to 28s. per week; but in Scotland higher rates are common, and the average may be taken at 32s. a week. A foreman baker in a small bakehouse earns about 5s. more than an ordinary hand. A youth as improver may be had at

15s. a week in London, or at 10s. a week in the provinces. He will be useful outside the bakehouse as well as in it, and may do the customers' rounds with board, barrow or cart. But the small baker should never trust entirely to his improver, but should take care to come into personal contact with his customers periodically. Thus he may receive complaints, learn the wishes of the customers, and check the accounts owing, if there be such, for a youth entrusted with the handling of money is often tempted to appropriate it, a practice which usually begins in borrowing.

Buying Flour. There is great competition among the millers for the custom of the baker, hence there is no uniformity in the terms upon which he is required to pay for his flour. Payment at one month under discount of 1¼ per cent., or 6d. per sack, is not uncommon. Larger credit is usually net, or with added interest proportionate to the credit. But millers frequently run over each other in attempts to secure orders, and, as a matter of fact, a baker can nearly always get flour, even if he have not a penny to pay for it. This accounts for a good many of the bankruptcies in the trade, for if credit were not so cheap, fewer men with ambition, but without means, would be tempted to establish themselves. In a fluctuating commodity like flour, forward buying under contract is common, also speculative buying, even beyond the consumptive capacity of the individual. The ability to estimate a firmer market is a desirable quality, and its exercise is very profitable, but, of course, the risks are proportionate.



5. BAKING OVEN IN CANADIAN BACKWOODS

Selling Prices. The sack of flour weighing 280 lb. produces from 92 to 96 quartern loaves. The rise or fall of 4s. in the price of a sack of flour is supposed to raise or lower the price of the loaf one farthing. But it often does not do so. There are fools in every trade, and the bakery trade has its proportion. Competition causes many bakers to cut prices below remunerative level, and this not only prevents the cutter from making his proper profit, but also makes his competitors and his neighbourhood work for less than a fair price. It is recognised that the price of the product of each sack of flour should be 14s. in excess of the flour cost. From this 14s. the baker has to pay for his yeast and other ingredients, labour, fuel, and working expenses. Some bakers are content with a gross profit of 10s. per sack, and they may make a living by hard work, but after they have worked themselves to death they will scarcely be able to leave behind them sufficient money to pay for a respectable tombstone.

Upon small goods and confectionery retail prices should be not less than double that of the materials used. The loss upon these is greater; they are saleable only when fresh, and the baker must choose between having on hand a good stock right up till the hour of closing each night, with a consequent certainty of having a good percentage of stale stock, or of displeasing customers by running on short stocks, and, therefore, of being unable to do a good evening trade.

Special Breads. There has been created a good demand for special breads of the Hovis and Bermaline types. In the one, the usual loaf weighs 1 lb. 10 oz., and retails at 3d. In the other, it is usually 1 lb. for 1½d. Such breads pay well—quite double the profits yielded by the common loaf. Their manufacture is very simple. It is necessary only to follow explicitly the directions issued by the firms who own the processes. Very small quantities may be made quite as easily as large quantities, and care should be taken not to make too much, because to have to sell it as stale is to lose all the advantage of the higher profits possible. These special breads stand a much heavier proportion of water than ordinary flour.

Bakehouse Laws. The law imposes certain distinct obligations upon the proprietors of a bakehouse. If machinery be used—and the modern bakehouse fills this condition—the place is subject to the general provisions of the Factory Acts. If the establishment be a retail one, these provisions are enforced by the Medical Officer of Health of the local district authority, and not by inspectors under the Factory Acts. The interior of the bakehouse must be limewashed, painted, and washed at certain specified times, and must not be used as a sleeping-place. No building underground may be used as a bakehouse, unless it was so used prior to January 1st, 1896. Care is also necessary that children and young persons be not employed in a factory, except within such hours as the law permits. The Bread Acts and the Sale of Food and Drug Acts are framed to prevent adulteration. The introduction of alum into bread, for instance, is not permitted, although technical opinion is not unanimous in condemning its use. Many other ingredients may not by law be incorporated in bread, but alum seems to be the only adulterant regarding which action has been taken for some years. The quartern loaf is supposed to weigh 4 lb., but most of the bread now sold is in half-quartern, or 2 lb. loaves. In the present state of the law, the baker may sell his bread "of any weight or size he thinks fit," provided that he sells it by weight, which means that the weight must be declared at the time of sale.

The Shop. We shall now step from the bakehouse into the shop. The best attendant for the baker's shop is a member of the baker's family in the modest venture we have been discussing. Indeed, the whole business of a baker is, more than almost any other, a family affair, and success depends upon each individual doing his or her allotted part well. The baker's wife is the best person behind the baker's counter. There is scope for womanly taste and skill in rendering the shop inviting, and in setting out its contents in an appetising manner.

The Window. The baker has wide choice in window arrangement. There is being exhibited a tendency to refrain from overloading the windows with stock, and it must be remembered that a few articles tastefully arranged are infinitely better than a mass of stuff which remind one of the painful necessity of eating rather than of the pleasures of the table. Our illustration [1] shows a good design in a suspending arrangement, which we select from the specialities of Messrs. F. E. and G. Maund, of London. It is in lacquered brass, relieved with burnished copper, and has two ground and polished plate-glass shelves. The price of an article of this sort is about £6. It may be objected that too much show of metal-work attracts attention to the fittings instead of to the displayed merchandise. Excellent brass and plate-glass suspending arrangements may be had at half this price. Black iron window fittings, though excellent in many places, are not desirable in a confectionery window. Nothing looks better than brass and glass.

Interior Decoration. Money may be judiciously spent upon internal fittings and decorations. White enamel paint is the most appropriate for a baker and confectioner's shop. Our illustration [2] shows an attractive interior. Assuming the shop to be 16 ft. by 20 ft., the cost of fitting up would be about £150 in deal and £175 in American white wood. This includes complete fittings on both walls, two counters, a cash-desk, four air-tight glass cases, marble tops to the counters, and back fittings and full-plate mirrors at back of the shelving. Expense could be modified with details

Show-stands. There is no excuse for the baker and confectioner who neglects to have attractive show-stands about his counters. Makers of such things offer a selection that is embarrassing. Less than a five-pound note will purchase the strong, five-tray stock rack shown in 4. The trays as they come full from the bakehouse may be slipped upon the angle brackets of the rack. To fill up a corner either in the window or on the counter or shelf, the type illustrated in 3 is a favourite. It may be purchased for 30s.

Purchased Merchandise. The baker —especially if he be also a confectioner—does not manufacture all that he sells. He may handle factory biscuits and sweets. The chief value of factory biscuits is that they fill up space, making an appearance in a shop which might, when the trade of the day is over, be very bare indeed without them. They seldom yield a larger profit than 1½d. to 2d. per pound, and there are a good many quarter-pound customers. Sweets and sugar confectionery pay much better—seldom less than 100 per cent. on cost price, and often a good deal more. They are, therefore, worth encouraging.

Horse and Van. The upkeep of a horse and van in a city like London cannot be reckoned at less than 20s. per week. In country places it may be somewhat less, down to 12s. a week in a village. A good van fresh from the works costs £35, but a second-hand one suitable for a new start may be had for half this figure. If cheaper than the latter sum, there is usually something wrong with it, and it often happens that investment in a new vehicle would have proved more economical than the purchase of a second-hand article. Paint, like charity, can be made to cover a multitude of sins. The chief point in buying a second-hand van is to see that the wheels are good. The price of a suitable horse varies considerably; £15 must be paid for one, and more, if possible. The sum mentioned may include a spavin and a few sand-cracks, but one cannot have everything for three five-pound notes. If the baker does not aspire to employ animal traction, £10 to £15 will purchase a good covered baker's barrow or a cycle delivery carrier.

Handbooks. There are many handbooks on baking and confectionery published. We suggest the names of a few that are really meritorious.

"The Bread Acts," by J. F. Rowe, 6d.; "Lectures on Bread-making," by John Kirkland, 2s. 6d.; "Practical Hints on Flour," by W. T. Bates, 1s.; "Hot-plate Goods," by R. Gommez, 9d.; "Slab Cakes," by F. Houghton, 3s. 6d.; "The Art of Confectionery," by George Cox, 10s. 6d.; "Figure Piping and its Uses," by F. Russell, 2s. 6d.; Book of Designs, by Herr Willy, 5s.; "Jago's Science and Art of Breadmaking," 16s.; and "Jago's Principles of Breadmaking," 2s. 6d.

The Bakers' and Confectioners' Exhibition, held each September in the Agricultural Hall, Islington, London, is highly instructive for the practical baker who attends it with his eyes open.

WHAT WE KNOW OF THE ETHER

Its Mass and Properties. Ether and Matter. Theories Regarding the Cause of Gravitation. Radiation Pressure and its Bearing on Gravitation

Continued from page 900

By Dr. C. W. SALEEBY

WE cannot go far with the study of gravitation before we find it necessary to imagine the existence of an invisible something which is now called the *Ether*. The history of the idea that apparently empty space is filled with an infinitely delicate substance of great importance is very interesting.

What is Light? The first term that was employed was the *luminiferous ether*—that is to say, the light-bearing ether. The older theory of the nature of light—a theory supported even by the great Newton—was that it consists of the propulsion of countless hosts of minute bodies, some of which enter the eye and cause the sensation of light. But that theory had to be abandoned, and there was substituted for it the now universally accepted wave theory of light, which asserts that light is a kind of wave motion—in what? Between us and the sun, for instance, there is apparently nothing at all except a few miles of air. If light be a wave motion, then the space between us and the sun must be filled by an invisible something, in which the motion occurs, and this invisible something was called the luminiferous ether. Its existence, at first merely suspected, is now beyond dispute. We know that it transmits not only the waves of light, but also the waves of radiant heat, the Hertzian waves of wireless telegraphy, the ultra-violet waves which now cure lupus, the Röntgen rays, and many more. So certain is the existence of the ether that modern chemistry is inclined to believe that what we call ordinary matter is none other than a special product of the ether—in other words, that the ether is the mother of matter. Now, what has all this to do with gravitation?

The Mystery of Influence. When we come seriously to think about the fact of gravitation, we find it impossible to understand how one body in space can exercise an influence on another, unless there be some medium between them by which that influence can be transmitted. Now, what can this medium be? Dr. Thomas Young—a distinguished physician to St. George's Hospital, London, founder of the wave theory of light and discoverer of the key to the Egyptian Hieroglyphics—declared that "a luminiferous ether pervades the universe, rare and elastic in a high degree." Surely, if there be such a luminiferous ether, it must be the medium by which the force of gravitation is transmitted. So far this is all very well, but we soon encounter the most serious difficulties.

In the first place, if the ether is to vibrate so as to give rise to light, it must have the property of rigidity, as found in solid bodies, such as a stretched string. But it is very difficult to square our idea of such a rigid body with the motion of matter through it. In fact, we seem compelled to endow the ether with a number of properties which appear to be incompatible with one another. Indeed, two great philosophical students of science, Auguste Comte and John Stuart Mill, entirely disbelieved in the existence of the ether at all, and we can sympathise with them. Nevertheless, it is impossible to agree with them, for the fact of gravitation, if no other, compels us to assert the existence of such a substance. If there be no ether, we must believe in the possibility of action at a distance—that is to say, the possibility of one thing affecting another without the existence of any means of communication between them. So we must do our best, despite difficulties, to ascertain the nature of the ether, being well assured that, once we have solved this problem, and the allied problem of the relation of the ether to the ultimate constituents of matter, we shall have in our hands the key to the problem of gravitation.

The Ether and Matter. Now, we have already seen that weight is a consequence of gravitation, and we are compelled to assert that the ether, by which one portion of ponderable matter exerts gravitation and attraction upon another, is itself without weight. Thus, in contra-distinction to the imponderable ether, we often speak of "ponderable matter." But to assert that it has no weight is by no means to assert that it has no mass; our previous inquiries have already shown us this. In order to do the work which we assert of it the ether must have mass, and here we encounter a source of confusion which is extraordinarily widespread. It actually vitiates a large part of the argument of no less a person than Mr. A. J. Balfour, in his Presidential Address to the British Association, at Cambridge, in 1904. Referring to the modern doctrine that ordinary matter—ponderable or weight-possessing matter—is only a specialised form of ether, Mr. Balfour declared that "matter has been not only explained, but explained away." Like so many others, he has completely failed to realise that all our notions of the ether, without exception, *are derived from our notions of matter*. The differences between the two are no doubt profound, since, for instance, one has weight, whilst the other, without weight, is yet the cause of weight; but, nevertheless, in discussing the ether we are discussing a *material* entity—rarer perhaps a thousand millionfold than the rarest gas, but nevertheless material.

Properties of the Ether. Having cleared our minds of this confusion, we must proceed to ask ourselves what are the properties which we can assert with any decision of this mysterious substance. According to a great student of the subject, Lord Kelvin himself, the ether must be continuous ; there must be no holes, gaps, or cracks in it ; it cannot be atomic in the sense that matter is atomic ; it must consist not of a collection of particles, but of an absolutely continuous substance. A word frequently used to express this property is *homogeneous*. The ether must be homogeneous—continuous and uniform throughout.

A Stone in a Pond. Even in accepting this apparently simple and necessary assertion, we find ourselves met with a difficulty, as Herbert Spencer pointed out. For how are we to conceive of a wave movement in a continuous medium ? Of course, we are familiar with wave movements in mediums which are apparently, but not really, continuous. When you throw a stone into a pond you excite a wave movement in a medium which looks continuous, but, of course, it is not so in reality. You know quite well that certain particles of the water must be moving past certain others, and if this be so, the medium is not really continuous. But indeed how can there be any wave motion in a continuous medium ? The waves of light in the ether must mean—if they mean anything—a state of more or less local motion, and there can be no local motion in a medium which is really continuous. Needless to say, we are not yet in a position to explain this difficulty. If we are honest, however, we have to state it, and the people who always rejoice at the difficulties of science may have their laugh if they will. "The laughter of fools," said Solomon, "is as the crackling of thorns under a pot."

The Light through the Window. Now, the ether is certainly continuous in the sense that ordinary matter offers no interruption to its continuity. It has sometimes been asked what happens to the ether as the earth passes through it in her endless journey round the sun. It has been thought that the earth must push the ether aside, just as she would if she were passing through an ocean of water. This would imply, of course, that the ether is not continuous, since it suggests that from the exact portion of space occupied at any moment by the earth the ether must have previously been expelled. Certainly more in accordance with our modern views as to the ether is the doctrine that the matter of which the earth is composed flies right through the ether without in any way pushing it to one side. It must certainly be the case that the ether can exist in space which is apparently fully occupied by ordinary matter. Take, for instance, the passage of light through your window. A series of ether waves strikes one side of the pane of glass and emerges unchanged at the other side ; the waves brighten up the point of glass through which they pass ; there is certainly absolute continuity of the ether wave—that is, of the ray of light. This can only mean that there is ether present in the glass. It cannot possibly be explained as meaning that the ether wave on reaching the pane of glass is transformed into a glass wave, and that this glass wave, on reaching the inner surface of the pane, is retransformed into an ether wave, which has the same properties as the orginal one.

Lord Kelvin's Theory of the Ether. We speak advisedly when we say that the ether, somehow or other, is continuous. It is continuous not only within itself, but with ponderable matter. Only on the assumption that there is no break of continuity between ether and ordinary matter can we explain the transmission of light through portions of matter, or the fact that one portion of matter acts upon another gravitationally by means of the ether. Indeed, the only possible conception is that the ether is absolutely omnipresent, and that ponderable matter is a specialised manifestation of it. As to the essential relation between ether and ordinary matter various brilliant guesses have been made. Perhaps we must consider matter as consisting merely of points of extra density of the ether. That seems simple, but it is not very satisfactory. Perhaps we must consider that portions of the ether have somehow become cast in the form of vortex rings, like the rings issuing from a smoker's mouth ; this is the famous *vortex theory* of Lord Kelvin.

There are many problems still unsolved, but some things are, at any rate, quite certain. That there is an actual entity corresponding to what we call the ether, there can be absolutely no doubt whatever. Sometimes, when the biologists and the physicists are having a little quarrel, the former assert that the ether is a "convenient fiction," or a "baseless hypothesis," or something of the sort, but the reader may be assured that competent observers have no doubt at all that the ether does actually exist. He must not pay too much attention to what people say when they are angry. The difficulties of describing the properties of the ether in any intelligible manner we must freely and humbly admit. But we are getting nearer to a solution ; we have travelled very far even in the last five years. There is hope for physicists in the great mind of Lord Kelvin, though it is now in its eighty-second year. Even so long ago as 1888 he showed that certain of our difficulties in describing the properties of ether can be met, "provided we either suppose the medium to extend all through boundless space, or give it a fixed containing vessel as a boundary." The celebrated Baltimore lectures delivered by Lord Kelvin in 1884 give us a splendid exposition of the conception that the ether is really a continuous, homogeneous, non-atomic, elastic solid.

Let us now, having studied so far as may be the nature of the ether, return to the question of gravitation, and see whether we are able to express any opinion as to its cause.

The Cause of Gravitation. The study of the cause of gravitation is as difficult as it is important. Only in very recent years do we appear to be reaching the point at which we shall be able to make up our minds on this matter. For instance, the article on gravitation published by Sir Robert Ball in the "Encyclopædia Britannica," in 1880, and included in the last edition of that work, contains no allusion whatever to the cause of gravitation—not even a hint that the question may be raised at all. But there was little chance of understanding the cause of gravitation until we had at least arrived at somewhat truer notions of the nature of matter than those of the year 1880; and we may suppose that it really did not seem worth while to discuss a subject about which nothing whatever was known or seemed likely to be known. Indeed, we may quote the words of a writer, who says: "Since the time of Newton the doctrine of gravitation has been admitted and expounded till it has gradually acquired the character rather of an ultimate fact than of a fact to be explained." (Clerk-Maxwell.)

Flying Bodies in Space? The most celebrated theory of the cause of gravitation is that of Le Sage, of Geneva, published in the year 1818. He considers that the whole of space is filled with minute bodies flying about in all directions. These he supposes to be so small that they very rarely strike one another; they are almost immeasurably smaller, he fancies, than the particles of ponderable matter against which they must very frequently strike.

Now, if there were only one single body in space it would receive on the average about as many blows on one side as on another, and thus would not be urged to move in any particular direction; but if we imagine two bodies in space it is plain that each of them will shield the other from a proportion, however minute, of these tiny projectiles conceived by Le Sage. Thus, the side of each body which is next to the other body will receive fewer blows, and the two bodies will be moved towards one another in virtue of the excess of blows they receive on the sides furthest from one another. Now, supposing that were the actual state of affairs, it would yield a law of gravitation which bears an extraordinary resemblance to the law we know. For instance, the force of attraction would vary inversely as the square of the distance between the two bodies. Further, it would vary directly in proportion to the areas of sections of the two bodies taken through them at right angles to the line between them. Thus, if we can imagine bodies so constituted that these areas—the areas that shield the other bodies from blows—are proportional to the mass of the bodies, we find that the law which would hold if Le Sage's theory were true is absolutely identical with the observed law of gravitation. Thus, the theory of Le Sage is not only a signal instance of the brilliant use of the scientific imagination, but—and this is very much more important—looks as if it might be, in some measure, at any rate, an approximation towards the truth.

Criticisms of the Theory. An obvious objection will present itself. As far as we can possibly detect, gravitation acts between any two bodies with precisely the same force, whether or not there be a third body intervening between them. The attraction exercised by the sun upon the moon is apparently just the same when the moon is eclipsed—that is to say, when the earth intervenes between her and the sun, as at other times. Hence, as Le Sage himself pointed out, it is necessary to suppose that only a very few of the particles which he imagines to be flying about space are stopped by any solid body, most of them passing on through the relatively wide intervals which we must conceive as existing between the ultimate particles of ordinary matter.

Clerk-Maxwell spent considerable thought upon criticism of Le Sage's theory—"the only theory of the cause of gravitation which has been so far developed as to be capable of being attacked and defended." Those words were written more than 30 years ago. This is not the place in which to consider the various more or less recondite criticisms made by the great physicist, but we may just briefly note that one of the chief difficulties suggested—namely, that the energy contained in these rapidly moving particles of Le Sage would necessarily raise to a white heat every material body they encountered, is disposed of if we are able to accept the theory of Lord Kelvin—that the particles are not mere points, but are of the nature of vortex atoms.

Now, the reader may well ask, what has all this about rapidly moving particles flying in all directions through infinite space to do with what we have already asserted, concerning a continuous, non-atomic—*i.e.*, non-particulate—elastic ether? And certainly we admit that there does seem to be very little compatibility between the two conceptions; but it must now be shown that a very recent and very important discovery has led us up to a point at which it seems possible that this promising theory of Le Sage may be re-stated in a form that is entirely compatible with our modern conceptions of the nature of the ether.

The Pressure of Light. The subject of gravitation is so colossal and so fundamental that we are compelled to treat it as a whole, and therefore we offer no apology for taking out of what perhaps may be regarded as its proper place the subject of radiation-pressure—and more especially the pressure of light. Since this subject has lately been shown to have no small bearing, as it appears, upon the essential nature of gravitation, we cannot possibly afford to wait for its discussion until we reach the part of our course which deals with light.

As we have seen, Newton taught that light—or rather the objective basis of light—consists of the propagation of minute particles or corpuscles which travel at immense speed in straight lines. In thus advocating what is called the corpuscular theory of light Newton retarded the progress of optical science for many decades after his death—a conspicuous instance of the malign power of authority. Now, if light consisted of a corpuscular bombardment, it would exercise, however faintly, a pressure not distinct in principle from the pressure of one hand upon another; and it has long been believed that light does exercise such a pressure, but the experimental evidence of this belief has not been forthcoming. In one respect, this is fortunate; for if it had been possible to quote experimental proof that light exercises a pressure, the fact would certainly have been regarded as strongly in favour of the (false) corpuscular theory of light as against the (true) wave motion theory.

But when Clerk-Maxwell associated light with other forms of radiation in the ether, such as radiant heat and electricity, and established what is now called the electromagnetic theory of light—now universally accepted—he showed that even on this theory, just as much as on the discarded one, light must exercise a pressure. For convenience of reading we use the word light, but it must be remembered that this pressure is common to light and all other forms of ethereal wave motion of the same kind. It makes no difference to its pressure whether or not a particular rate of motion happens to have a special action upon the human eye. Clerk-Maxwell actually proceeded, by use of various abstract mathematical considerations, to frame a formula which would express, he declared, the measure of the pressure of light—a pressure which had not then been demonstrated.

The Radiometer. It is now many years ago since Sir William Crookes followed those who had attempted to demonstrate what we shall henceforth know as radiation-pressure. His *radiometer* is familiar to all—a series of delicately balanced vanes, bright on one side, blackened on the other, which lie in a partial vacuum in a glass bulb. Exposure to sunlight or even the end of a lighted cigar causes these vanes to revolve. But it was shown that this effect is not due to light-pressure, but to the unequal heating, and consequently unequal atomic movement, of the remaining air in the bulb, due to the varying absorptions of the bright and blackened surfaces of the vanes.

Some four years ago, however, radiation-pressure was positively demonstrated, independently, by the great Russian physicist Lebedew, and by two American observers, one of whom—Professor E. F. Nichols—excited much interest amongst the physicists in this country by lecturing and showing his original apparatus at the Royal Institution, in May, 1905. Lebedew's method was based on the advice of Maxwell, which was simply to obtain as high a vacuum as possible, so as to exclude the action of heated gases, as in the radiometer, and thus to detect any action due to the pressure of light alone.

Radiation-Pressure. Professor Nichols and his co-worker proceeded on different lines. They employed no vacuum, but were nevertheless able to exclude the gaseous action, which takes some time to manifest itself, whereas the effects of light-pressure are naturally instantaneous. It is impossible to describe on paper the details of the method which the discoverer found complicated apparatus necessary to explain. Let us merely observe that the fact of radiation-pressure has now been established, that its amount has been measured, and that the measurements coincide within extraordinarily narrow limits with the results reached by Clerk-Maxwell, working from purely mathematical assumptions. Given that radiation-pressure is a fact (and a universal fact, be it remembered), the question now is as to the general significance of this most important discovery.

Of course it explains that for which an explanation has long been hoped, the development of tails by comets when approaching the sun. It explains not only the formation of these tails, but their increasing width as they pass away from the nucleus of the comet, the cases in which there are several tails—as in the celebrated comet of Donati—and the manner in which they push their trains in front of them as they leave the royal presence; but this does not represent anything but a tiny fraction of the cosmic significance of radiation-pressure.

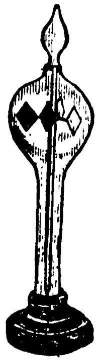
A Universal Force Opposed to Gravitation. It is as we have already hinted, a mere accident, so to speak, of our constitution, that we can see certain forms of radiation, can feel others, and can perceive yet others not at all. We have seen that the Hertzian waves, the infra-red waves (that is to say, the waves that lie just below the red rays in ordinary sunlight), the rays of light, the ultra-violet rays, and many more, are related to one another, just as one musical note is to its neighbours.

Wherever, then, there is a luminous body, wherever there is a body which is possessed of any heat whatever, wherever there is a body which is a source of electric energy, there is a source of radiation-pressure. It amounts to this then, that we now have positive evidence of a universal force which is comparable to gravitation, but acts precisely in the opposite direction. As gravitation attracts, radiation-pressure repels.

In the case of large bodies, as the sun and the earth, radiation-pressure does not amount to one billionth part of gravitation, but in the case of the particles in a comet's tail we see that, despite the enormous mass of the sun, radiation-pressure far outdoes gravitation. In other conditions the two forces will balance one another. Now, every body that is above the absolute zero of temperature exerts this force—and at all distances—its power decreasing with distance in the same ratio as does the power of gravitation. The unqualified assertion of Newton, then, that all bodies whatever attract one another with a force which is proportionate to their mass and varies inversely as the square of the distance, is found to be only ideally true; for most, if not all, bodies also repel one another in accordance with an equally precise law. It is possible to combine the two into an algebraic expression, without reference to which the law of gravitation should now no longer be stated.

"One Universal Heap of Matter." Let us now briefly consider some of the consequences of radiation-pressure—of the fact that there is a mutual repulsion as well as a mutual attraction between bodies. In the first place, we must reconsider the view which has often been maintained that all matter in the universe will ultimately be agglomerated into one dense heap in virtue of gravitation. Again, we find that we now have another factor besides the action of the tides, pointed out by Sir George Darwin, to consider as interfering with the stability of the Solar System. But furthermore, we observe, as has been already shown, that the first law of motion can no longer be held as unqualifiedly true, even if the motion be through an untenanted and perfectly frictionless ether. It is said that, in such conditions, a body in motion must so move, in a straight line, and at the same velocity eternally, if no force be impressed upon it. That, doubtless, is really true, but when are the conditions realised? For any body that emits radiant-energy—*e.g.*, any body such as the sun or the earth—contains within itself a cause of retardation. On its onward path it leaves waves of radiation behind it and sends them in front of it. But in so doing it tends, as Professor Poynting has shown, to "crowd upon" the waves in front, whilst those behind it are "thinned out." In other words, the radiation-pressure will be greater in front than behind, and therefore the speed of the body—and this applies alike to a Sirius or a bullet—will constantly be diminished.

Its Bearing on Gravitation. In considering the future of the Solar System, then, we have to recognise, in planetary radiation, and in the effects of the solar radiation, causes which tend to retard that motion in virtue of which alone the planets are prevented from falling into the sun. But it appears evident that such a catastrophe, even were it to occur in such a fashion as not to induce the evolution of much heat, would by no means introduce a final state of "death" of the Solar System, as used to be thought.



RADIOMETER

And now for the bearing of all this on gravitation. Here is a universal force which acts in a direction precisely opposite to that of gravitation, and which is in certain conditions more powerful than, in other conditions as powerful as, and in yet others less powerful than, the more familiar force.

It is plain, then, that, as we have already said, it will not do for any future writer to discuss gravitation without reference to the fact of radiation-pressure. But does this new discovery help to give us any clue to the cause of gravitation? That would be a surprising contribution from a source which interferes with the action of gravitation. But it appears to be conceivable. We recall the theory of Le Sage, which we have just discussed at what might have seemed, a year or two ago, disproportionate length. Suppose, for instance, that for the pressure due to the minute particles pictured by Le Sage—particles of which we have seen that subsequent science knows nothing at all—we substitute the pressure of radiation, might we not then be able to find a germ of truth in Le Sage's theory—indeed much more than a germ—even though that theory requires considerable modification in its statement?

The subject is yet too new for dogmatism, but we note that no less an authority than Sir George Darwin lately read before the Royal Society a paper dealing with the possibility to which we have referred, the possibility of harmonising Le Sage's theory of the cause of gravitation with the fact unsuspected by him, the fact of radiation-pressure.

What we Cannot Understand. It would certainly be too much to say that we shall ever have to look upon gravitation as merely the negative aspect of radiation-pressure, just as Le Sage imagined gravitation to be merely the negative aspect of the repulsive pressure of his imaginary particles; but it will be strange indeed if there does not turn out to be a most intimate relation between these two universal facts. This, then, is all that we can as yet possibly say concerning the cause of gravitation. It is vague and tentative enough, the reader may say, but nevertheless it opens out new possibilities of knowledge and comprehension which were quite unsuspected by the nineteenth century.

Finally, let us note how close we are to the inconceivable. You could push one of Professor Nichols' recording vanes with a pin, or by a puff of the breath. In each case some material is moving against the vane. Similarly, you can push or "strike" the vane with a beam of light. But in this case—though light-waves travel at a known speed—nothing material, even if we include the ether as material, moves onwards, as does the pin or the puff of air. Try to conceive how a thing may be struck and moved by that which has no material existence. Failing this, try to form a "clear and distinct idea" of the *that* in question! Only the most foolish kinds of materialists, left high and dry from thirty years ago, think that they or anyone else can really understand the inner nature of Energy

AND ROOT CROPS

Varieties of Clover. Twofold Value of the Plant. Root Crops Described: Mangel, Beet, Turnip, Kohl-rabi, Carrot, Parsnip and Potato

By Professor JAMES LONG

CLOVERS

This useful plant (Nat. ord., *Leguminosæ*) belongs to the genus *Trifolium*. The principal varieties are of great value for feeding sheep on the ground, and thus improving both stock and soil—for hay, and occasionally as green forage. They are handsome, with somewhat round-headed blossoms and compound leaves, each leaf being provided with leaflets, while the seeds are produced in pods, or legumes. The chief varieties grow admirably upon the medium and heavier soils, and are sown both for temporary and permanent pastures, while the majority are found in good meadows. The cost of the seed together with its weight is given in the table below.

COMMON YELLOW CLOVER, OR TREFOIL

Broad Red Clover. This variety (*T. pratense*) bears a round, purplish blossom, with leaflets upon which are imprinted a mark resembling a horseshoe.

The colours of the heads of each variety of clover, together with the tiny flowers themselves, the seed-pods and the seed, should be examined by the student that he may be practically acquainted with each. Red clover is cut or fed twice in the year after it is sown, or it may be cut once and subsequently fed or mown for seed. This variety will stand two years, and sometimes more, but it cannot be depended upon. It is seldom grown more than once in eight years on the same field owing to its liability to what is known as "clover sickness." When sown alone, from 14 to 20 lb. of seed are used per acre. When converted into hay, the crop should yield 3 tons in the two cuts, sometimes more. Clover is a most important crop in the ordinary farm rotation, but it is liable to attacks of a parasitic weed known as dodder (see illustration), the seed of which may find its way into clover seed sample.

Perennial Red Clover or Cow Grass. This variety (*T. pratense perenne*), which carries a slightly darker purplish blossom of somewhat smaller size, is closely akin to broad red clover; it stands longer, but only supplies one crop for cutting. The mark on its leaflet is more angular than that of the broad red, which, as indicated, is more rounded in form.

White Clover. White clover (*T. repens*) is common to most of the heavier classes of soil, and though its presence is not apparent, it soon covers a field with rich herbage in response to a good dressing of dung or phosphate of lime, for which reason phosphatic manure is of great value on pastures as well as on meadows.

Alsike. A perennial with a white blossom tinged with pink. It is a strong, vigorous grower, extremely useful in clover and grass mixtures, whether for temporary or permanent leys, and is especially adapted to the heavier classes of soil. It is occasionally used instead of red clover, where, owing to fear of disease, it is not

English Name.	Botanical Name.	Percentage of germination.	Weight per bushel.	No. of seeds in lb.	No. of germinating seeds in lb.	Cost of 1,000,000 germinating seeds.
			lb.			
Broad red clover	Trifolium pratense	98	66	232,000	227,360	3 7
Cow grass, or perennial red clover	Trifolium pratense perenne	98	66	218,000	213,640	5 4
White Dutch clover	Trifolium repens	98	68	782,000	717,360	1 8
Alsike, or hybrid clover	Trifolium hybridum ..	98	66	718,000	703,640	1 3
Crimson clover	Trifolium incarnatum ..	98	66	118,000	115,640	2 10
Trefoil, or yellow clover	Medicago lupulina	98	68	319,000	312,620	1 2
Hop trefoil	Trifolium procumbens ..	96	66	—	—	—
Birdsfoot trefoil	Lotus corniculatus	98	65	412,000	403,760	2 9
Greater trefoil	Lotus major	90	64	360,000	—	—
Lucerne	Medicago sativa	98	65	224,000	219,520	4 0
Kidney vetch	Anthyllis vulneraria ..	98	64	193,000	189,140	4 2

deemed advisable to sow the latter. 14 lb. of seed are used per acre when it is grown alone. Crimson clover is described in the chapter on forage crops.

Trefoil. This belongs, as the foregoing table shows, to the genus *Medicago*. Known also as yellow, or hop, clover, it grows upon various soils, and is specially adapted to those which are poor or dry. Trefoil, which is sometimes known to farmers as black medick, has a hairy stem and leaves, and produces seed of a brownish yellow, which is frequently used in mixtures, especially on down lands, many of which are chalky in character. The seed sown for a pure trefoil crop is 15 lb. to the acre.

Hop trefoil, which flourishes on limestone pastures, can scarcely be described as a cultivated plant. Birdsfoot trefoil, although a valuable plant, is practically wild, and is commonly found in poor or dry soils of various classes. Its flowers, first almost crimson, change to brilliant yellow, while the peculiar form of the seed-pods has given rise to the common term birdsfoot. The Greater Birdsfoot Trefoil does not adapt itself so well to dry soils or soils which are of an extremely poor character.

Zigzag Trefoil is useful in pastures, but, like hop trefoil, is seldom found in seedsmen's or farmers' mixtures. The Kidney Vetch, again, is seldom sown unless under special conditions. It is common to pastures of various classes, especially those of a sandy character. The student will not fail to recognise it owing to the peculiar form of its yellow flowers, commonly known as "ladies' fingers."

ALSIKE CLOVER

RED OR BROAD CLOVER

PERENNIAL WHITE CLOVER

Twofold Value of Clovers. The student of agriculture can scarcely devote his attention to any family of plants which is of greater importance than the clovers. Their value is twofold; they produce a very large quantity of forage of the highest feeding value for stock of all classes—we include swine and poultry—and they materially add to the fertility of the soil, even though the crops be entirely removed from the surface. The clovers, like peas, beans, vetches, lucerne, and sainfoin—all of the same natural order, *Leguminosæ* —are known as nitrogen gatherers. How they appropriate the nitrogen of the atmosphere is described in the chapter on soils. It is possible to grow much larger crops than the average British yield by greater liberality in the employment of phosphatic manure and of potash, where this mineral is needed. We may further add that if by such a form of manuring the weight of a crop is increased, the richness of the soil will also be increased, and a more than usually successful succeeding crop practically ensured.

When well fed with the mineral fertiliser the clovers are enabled to appropriate more nitrogen, and thus to produce more herbage. At the same time, the soil is enriched owing to the additional nitrogen in the roots and the unexhausted phosphates and potash.

ROOT CROPS

The Mangel. The mangel (Nat. Ord., *Chenopodiaceæ* [*Beta vulgaris*] is a biennial, deep tap-rooted plant, which thrives on the stiffer soils, especially loams, in most parts of England, the north excepted. There are many commercial varieties, which are divided into the Long Reds, and the Globe and Tankard, or intermediate shaped yellows. The mangel is grown to large size, and we have measured bulbs 37 in. in circumference, six of which scaled 131 lb. It needs rich soil or ample manuring, especially responding to dung, nitrate of soda, and salt. Where the dung used is small in quantity, these artificials may be supplemented by super-phosphate on soil, rich in lime, or, where this is deficient, basic slag. The seeds grow in capsules, each of which contains from three to five. They are sown at the rate of 7 lb. to the acre by the drill, or, if dibbled by hand, much less will suffice, but by this method they are more liable to be taken by field mice. A bushel of seed weighs about 21 lb., each lb. containing over 20,000 seeds. Where the crop is grown from seed, it should reach 50 bushels to the acre. The mangel crop may reach any figure, from 10 to 80 tons per acre, with 3 to 5 tons of tops, but 30 tons may be regarded as quite satisfactory. It is rich in sugar, of which it contains approximately 8 per cent., but the proportion varies largely in accordance with the variety.

TANKARD SWEDE

KOHL-RABI

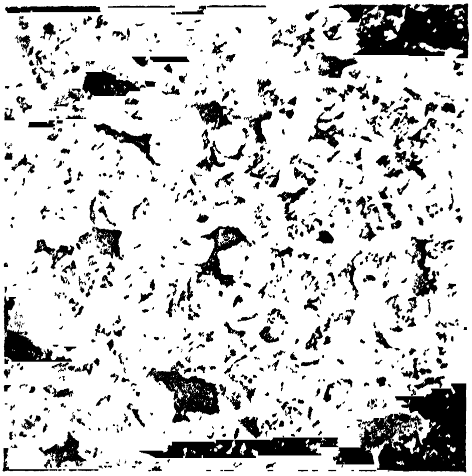
The Beet. The beet is a modification of the mangel, having been improved by selection; may contain over 14 per cent. of sugar, the production of which is influenced by abundant sunshine. The weight of a mangel crop is not an actual indication of its feeding value, for a much smaller crop of one variety may contain a greater weight of feeding matter per acre than a much larger crop of another variety grown on the same soil under the same system of cultivation. The mangel is a suitable food for all classes of farm stock. It is preserved by clamping, or pitting, and is more suitable for consumption after the completion of the year, and is often in use to the following July. It contains more dry matter than either swedes (12½ to 11) or white turnips (12½ to 8).

Turnips. The turnip (Nat. ord., *Cruciferæ*) embraces the swede (*Brassica campestris*), known as Rutabaga on the Continent, and the common turnip (*Brassica campestris Raba*), both the yellow and white fleshed. It is a biennial, and one of the most valued of English plants, especially for sheep feeding on light land, which it enables the farmer to cultivate with success. The swede is hardier and richer than the turnip, from which it differs in two points, with the exception of one or two commercial varieties; it has a neck, which the turnip has not, whereas its leaves are bluer and smoother than those of the turnip. Both swedes and turnips vary in colour; in some the top portion of the bulb is purple, and in others green. Turnips and hybrids are grown in succession as sheep and stock foods, being usually consumed before the swede, owing to the fact that they will not stand severe weather. The swede, however, frequently passes unscathed through the winter, but it is always a wise precaution to lift and clamp or pit it for safety.

TANKARD TURNIP

Turnips of all kinds respond liberally to dung and phosphatic manure. The seed is sown by the drill, which deposits the chemical manure, where this is employed, at the same time, 3 to 4 lb. of seed being drilled per acre, and from 3 to 5 cwt. of phosphates. Sowing varies with the climate and the soil, but May and June are the chief months. The seed weighs 50 lb. to the bushel, there being 23 to the grain, and, therefore, about 160,000 to the lb. The bulbs weigh some 42 lb. to the bushel, but individual swedes may reach 20 lb. each. In measuring

FARMYARD SCENE: BRINGING THE MANGELS HOME



MANGEL SEED

a prize sample we found that some reached 37 in. in circumference, while the lot of six scaled 120 lb. Turnips, however, may reach almost the same weight. When the roots are singled to 18 in. apart, there are 19,360 to the acre; when 27 by 9 in., there are 26,000.

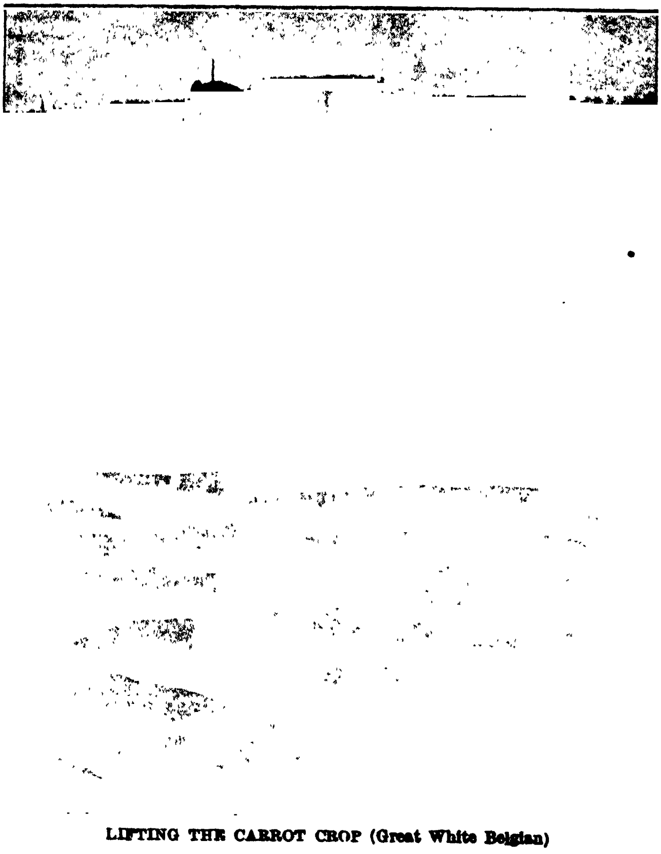
It was shown by Voelcker that turnips grown 10 to 11 in. apart were much richer in sugar than those grown 20 in. apart, hence the practice of growing swedes and turnips, beet and mangel, of medium size, and consequently closer together. When grown for seed, an acre of swedes yields about 28 bushels, and of turnips 20 to 24 bushels. A swede crop grown on good land under good cultivation should average 20 tons, and white and yellow turnips 22 tons to the acre. The British average for swedes and turnips covering ten years is, however, only 12¾ tons, as against 18¼ tons of mangels. The tops, or leaves, of the turnip crops are much heavier than those of the mangel, varying from 15 to 20 per cent. Unfortunately, the tops of swedes, like the tops of mangels, cannot be preserved; but ploughed into the ground they form a useful green manure. According to Voelcker and Warington the following are the manurial constituents removed in root crops.

Crops.	Weight.	Phosphoric Acid.	Potash.	Nitrogen.
	Tons.	lb.	lb.	lb.
Turnips with leaves ..	17	33	148	120
Swedes, do...	14	21	79	102
Mangels, do.	22	49	262	147
Potatoes with haulm ..	6	26	76	67

The depth at which seed is sown is especially important in the case of seeds so small as that of the turnip, which closely resemble that of the noxious weed charlock, belonging to the same family. The following table indicates the relation between growth and the depth of the soil.

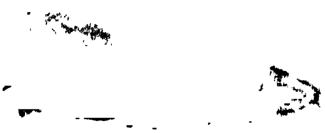
	Inches in depth.	From 40 seeds plants came up.	Proportion per cent.
Swedes :	1	31	77
	2	29	72
	3	20	50
	4	10	25

Kohl - rabi. Of this cruciferous plant (*Brassica oleracea caulorapa*), which may be described as a turnip-rooted cabbage, there are two varieties, the green and the purple. It suits heavy soils, on which cabbage thrives the best



LIFTING THE CARROT CROP (Great White Belgian)

Rabi is one of the most healthy foods on the farm; hardier than the turnip, and suitable for consumption at any time, it deserves to be more extensively grown. It possesses one advantage not common to the turnip, it transplants well, and thus, if grown in a seed-bed, it enables the cultivator to devote a longer time for the preparation of the soil into which it is to be removed. Unlike the turnip, it is seldom attacked by disease. If drilled in the field, from 2 to 4 lb. of seed are required per acre, but if sown in a seed-bed 3 to 4 lb. of seed will suffice for a rod of land. The weight of the seed reaches nearly 56 lb. to the bushel, the number of seeds in a lb. reaching about 125,000, while the crop produced per acre should reach 20 tons.



KIDNEY POTATO, SUTTON'S IDEAL

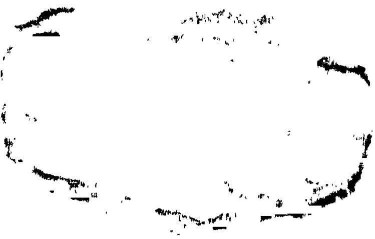
Field Carrots. The field carrot (*D. carota*; Nat. ord., *Umbelliferæ*; genus *Daucus*) is a biennial, growing best in a deep, fine, light soil, excluding those of the lightest character, while not thriving in the heavier soils. Although costly to grow, the carrot is one of the best known foods for cows. Under good cultivation it is grown to enormous size, and provides a crop of from 14 to 18 tons per acre, or even more. The seed sown (10 lb. to the acre), mixed for convenience with sand or fine ashes, weighs, in its natural condition, 15 to 18 lb. to the bushel, a lb. containing about a quarter of a million seeds. The leaves, although small, form an excellent addition to a ration

ROUND POTATO. SUTTON'S WINDSOR CASTLE

The Parsnip. The parsnip (genus, *Pastinaca*), of which one species is grown (*P. sativa*), is a hardy biennial, growing most freely in the lighter soils, especially if rich and deep. Like the carrot, it is an excellent and sweet food for cows, and is easily kept through the winter either clamped or in the ground. A good crop exceeds 12 tons to the acre. The seed, 6 to 7 lb. per acre, is drilled, and is better mixed with sand or very fine soil; its weight is 15 to 18 lb. per bushel, and there are about 100,000 seeds to the lb.

Potatoes. There is only one species of the potato grown in agriculture (*S. tuberosum*; Nat. ord., *Solanaceæ*; genus, *Solanum*), but there are many varieties, old ones being abandoned when they fail, and new ones produced. The potato is grown in two forms, the kidney, or fluke, and the round, and with skins of different colours, white, pink, and dark purple. It prefers a light loam, and best of all a rich sandy loam, but it is grown with more or less success in most soils except heavy clay. In Ireland it is largely grown in peat soils, in beds known as "lazy beds," with turnips between. In England it is usually planted in trenches, which are formed by the ridging plough. The soil must be fine, deep, and in good condition. Potatoes are now being grown on an increasing scale under glass for early consumption, and in the fields from tubers which have been encouraged to sprout before setting, the practice resulting in an earlier crop.

The potato is really a tuber, or underground stem, like the artichoke, and is extremely rich in starch, the real fruit of the plant being the berry, which resembles the tomato in this respect. Seed potatoes, or tubers, are known as sets. These are not the real seed, and consequently new varieties cannot be produced from them. A set should contain at least two eyes or leaf buds. It should be of good shape and size, dry and round. Large sets are frequently cut, and in this case it is preferable to use the rose, or large end. In the reproduction of costly varieties, tubers are frequently cut into a number of sets, each containing one or two eyes; the quantity of tubers, sets, or seed, planted per acre, ranges from 25 to 30 bushels, according to their size, a piled bushel weighing 56 lb.



PEBBLE POTATO, SUTTON'S DISCOVERY

The English crop, which is the largest in the world, averages about 6 tons to the acre, the British average being 5¾ tons; but under high cultivation 15 tons, and even more, have been grown. The potato is manured with dung and artificials; in soils liable to drought it is preferable to employ half a dressing of dung, 10 to 12 tons per acre, with a complete artificial manure combining nitrogen, phosphoric acid, and potash, the two latter being deposited in the drills at seeding time. The yield of the potato crop depends upon the vigour and suitability of the variety planted, the manure employed, and the thoroughness of the cultivation.

OUTLINES OF EDUCATIONAL TOURS ABROAD

Itineraries which will enable Travellers to witness the leading sights of Switzerland and Italy without waste of time

By J. A. HAMMERTON and WILLIAM DURBAN, B.A.

SWITZERLAND

No other country deserves so well the epithet of "the playground of Europe." The Swiss have not only a national genius for inn-keeping—so that their hotels are the best in the world, taken all round—but they know that their marvellous little land is an epitome of all the most magnificent types of scenery. And they have made their "Tourist Industry" quite a special vocation, laying themselves out in all directions to provide for the interests of visitors. Nowhere on the surface of the globe are the most attractive scenic phenomena of mountain, lake, valley, torrent, and glacier presented to the eye in so compact and accessible an area; while the attractions of the cities and villages, and of the simple and unsophisticated people, are, in themselves, inexhaustible.

Very much may be seen on each single day of a visit to Switzerland by means of the short excursions to various lovely spots, all within easy reach of this or that centre. Suppose that the visitor to Switzerland for the first time can spare only a week or ten days. He would be wise to attempt nothing more than a tour through the Bernese Oberland. Even in that brief time he could enjoy delightful glimpses of the glorious scenery to which Berne is the gateway, stopping a day each at such places as Thun, Interlaken, Kandersteg, and Meiringen. But though he could not do much more, he would know for the rest of his life what the sublime aspect of one Alpine range means. He would probably resolve on renewing and extending his acquaintance with those scenes of enchantment.

A Fortnight in Switzerland. If carefully planned, this will bring within the view [illegible] He must, of course, not linger long in any one centre, but the distances are so easy that travel is much more facilitated than in most other [illegible] It is quite possible within a full fortnight [illegible] certain portions both of the Bernese Oberland and also of the southern section of the country, where the Valaisian Alps rear their stupendous summits.

FIRST DAY. From London to Geneva.

SECOND DAY. The richest and largest of Swiss cities is GENEVA. It is the city of the Reformation. The day will be spent in surveying the memorials of that wonderful era. The *Cathedral*, with the beautiful Chapelle des Macchabées, contains black marble monuments and sarcophagi of Dukes Henri de Rohan and Tancred, and of Margaret de Sully. Calvin's chair is under the pulpit. The handsome quays and fine shops, the superb view of the Mont Blanc range, and the lovely lake prospects combine to render Geneva a place of peculiar charms.

THIRD DAY. This should be devoted to excursions from Geneva by the lake steamers. Amongst these the favourite trips are to *Eaux Vives*, *Vesenaz*, *Coppet*, *Nyon*, *Montreux*, and *Chillon*. The visitor has an ample choice for a delightful day.

FOURTH DAY. From Geneva, *via* Le Fayet, by electric railway to CHAMONIX. Excursion to the *Mer de Glace*. This needs no guide. The scene is marvellous, for the visitor is in the midst of the grand Alps of Valais and is by the side of a marvellous glacier. *Mont Blanc* towers above all.

FIFTH DAY. The excursions in the Valley of CHAMONIX are of incomparable beauty. But the tourist will, of course, choose that to the *Pavillon de la Pierre Pointue*, overlooking the *Glacier des Boissons*. Or he may make the easy ascent of *La Flégère* and here also enjoy a wonderful prospect.

SIXTH DAY. From Chamonix to MARTIGNY by the *Tête Noir*. This journey over a grand, wild pass, will make a memorable day.

SEVENTH DAY. By train to Visp and ZERMATT. At the latter place the visitor finds himself in perhaps the most supremely attractive spot in all Switzerland. Before him rises the *Matterhorn* in all its glory, with the *Breithorn* and the *Glaciers of St. Théodule* in full view from the platform of the Zermatt station. Here is the very "sanctuary of the Spirit of the Alps." In the churchyard and also beside the *English Church* are the graves of several victims of the Matterhorn disaster.

EIGHTH DAY. Excursion from Zermatt to the *Gorner Grat* and *Riffelberg*. Here are the grandest views in Switzerland. The mountain panorama is incomparable.

NINTH DAY. The tourist now leaves the Valaisian Alps, and is about to enter the Bernese Oberland for the second section of his trip. LAUSANNE is a very pleasant city interlude between the mountain experiences. A day here is delightful. The nave of the *Cathedral* is magnificent, and the many monuments in it are very fine. The town, on its terraces, commands splendid views of the Alps of Savoy, especially of Mont Blanc.

TENTH DAY. THUN and INTERLAKEN. The tourist can choose how he will divide his time at these two charming spots. He will enjoy that view of the peerless *Jungfrau* which can never be forgotten, and he can take little trips on either of the lovely lakes, *Thun* and *Brienz*. He should not fail to go along the latter, landing to see the famous *Giessbach Falls*.

ELEVENTH DAY. At MEIRINGEN, the grandest gorge in Europe invites a stay. In the *Aar Schlucht* are those tremendous *Falls of the Reichenbach* written about so romantically by Sir Conan Doyle in connection with the "Adventures of Sherlock Holmes."

TWELFTH DAY. At LUCERNE the tourist rests by one of the loveliest of lakes. He will see the famous wooden covered bridge over the Limmat, and will admire the beautifully situated town. Part of the first day should be occupied by a trip up the *Sonnenberg*, where refreshments may be enjoyed while the enchanting prospect is surveyed.

THIRTEENTH DAY. BASLE will repay a stay of a day at the conclusion of the tour. The *Rhine* is here a noble stream. In the *Cathedral* are to be seen the wonderful old frescoes of the *Death Dance*, as well as collections of mediæval curiosities.

FOURTEENTH DAY. The return journey to England.

Longer Tours. *Three weeks* would enable the tourist to stay longer at Lucerne in order to ascend the Rigi and Pilatus, each being scaled by a cog-railway. He could also devote two days to Berne and then give a day each to Zurich and Neuchatel. A *month* would add the additional delight of a stay at Grindelwald, where he would make acquaintance with the Jungfrau at close quarters, with the Wetterhorn, Eiger, and Mönch. He would go to Mürren and to the Lauterbrunnen Valley, and might even visit the Rhone Valley, going up the Grimsel Pass over to Meiringen.

Expenses. The expense of travelling in Switzerland is not great. Indeed, many who must study economy, and must be content with a few days, manage to spend a delightful week in the country at a cost of five guineas. But it is safe to reckon that a comfortable tour in Switzerland runs the tourist to the expense of about a guinea a day. Fares from London to Geneva are: First class, single, £4 16s. 1d.; return, £7 12s. 9d. Second class, single, £3 7s. 2d.; return, £5 9s. 10d. But for a mapped-out plan the tourist should adopt the rundreise system, as this circular ticket enables him within the country to effect a considerable reduction in the fare. The particulars are always easily obtained at any of the agency offices. But, of course, a special route must be decided upon.

The cost of living in Switzerland is very moderate. The managers of the hotels have learned to cater specially for Anglo-Saxon travellers. The charges vary greatly, but the average expense for a day and night, inclusive of everything, may be reckoned at 8 francs a day. Food everywhere is excellent. At the chalets during long Alpine walks milk may be obtained, but it is often the only thing available, so the tourist should take a small supply of food from his hotel for the day. To stay in the towns and to miss such walks is to fail to see the real Switzerland, therefore the tourist should traverse one or two of the glorious passes, such as those already named.

Books to Read. Canon Bonney's "Alpine Regions of Switzerland," Lord Avebury's "Scenery of Switzerland," J. A. Symond's "Swiss Highlands," Dr. C. Manning's "Swiss Pictures," Stephen's "Playground of Europe."

ITALY

Wherever else a traveller may have journeyed, he cannot feel that he has rounded off his experiences as a tourist until he has seen Italy, the land which is the fairest "favourite of the sun," the supreme delight of poets and artists, the marvel of history, and the garden of Europe.

Many of the noblest Alpine summits crown its scenery above the enchanting lakes of the north. All its immense coast-line is fascinating. And the long ranges of the Apennines—with old cities of Etruscan, Roman, and mediæval origin, in which incomparable treasures of art are enshrined perched on their crags—hide in their recesses and valleys countless exquisite beauty-spots. In this glorious peninsula the tourist finds the very acme of the delights of travel. A tour in this land ministers equally to health, to recreation, and to education.

Italy is a vast world in itself. No other land teems with so many centres of attraction. The immense length of the peninsula renders it impossible for the tourist in a brief trip to visit each section of the country. North Italy, Central Italy, South Italy, and Sicily need attention on separate tours. But the two first divisions may be seen and enjoyed in a cursory manner on a single tour, and the same remark applies to the last two. The best beginning, supposing that the traveller wishes to take a fortnight in some of the choicest portions of the country, may be easily indicated.

A Fortnight in Italy. If possible, this length of holiday should be arranged clear of the time needed for reaching the borders and for the homeward journey. We will map out the very best programme for a first tour of this length.

First Day. The tourist should proceed direct to Como by way of the St. Gothard Railway and Lugano. The ancient marble *Cathedral*, with the magnificent picture of the Adoration of the Magi, by Luini, is alone worth the whole journey. Take one of the enchanting trips on the lake, preferably that to *Bellagio*.

Second Day. Going on to Milan, visit early in the morning the incomparable *Cathedral*, one of the wonders of the world, with its 98 Gothic turrets and the 2,000 marble statues on the mighty roof. From this roof enjoy the wonderful Alpine view of Monte Rosa, Mont Blanc, and the Matterhorn. The *Picture Gallery* in the Brera Palazzo. The gem of the collection is Raphael's "Sposalizio." The *Church of San Lorenzo*, the most ancient in Milan, belongs to the fourth century.

Third Day. This also would be spent at Milan. The *Galleria Vittorio Emmanuele*, the largest bazaar in Europe. The *Piazza della Scala*, with the marble monument of Leonardo da Vinci. The magnificent triumphal arch built by Napoleon, called the *Arco del Sempione*. Excursion to the old monastery of *Santa Maria delle Grazie*, containing the famous picture of the 'Last Supper,' by Leonardo da Vinci.

Fourth Day. Arrive at Genoa. The *Palazzo Rosso*, with famous picture gallery, containing many masterpieces of Titian, Van Dyck, Luini, Veronese, Rubens, etc. The *Palazzo Bianco*, with smaller but excellent picture gallery. The *Palazzo Durazzo*, noted for its picture gallery with many works of the great painters of the seventeenth century. The *Statue of Columbus*, near the Harbour. The *Campo Santo*, celebrated for its beautiful monuments.

Fifth Day. Next in order would come Spezia, the Portsmouth of Italy, superbly situated. Royal dockyard. Lovely excursion along the bay to *Porto Venere*. Ruins of ancient *Church of S. Pietro* on site of a temple of Venus. Or, if preferred, take the equally delightful steamer trip by other side of the magnificent bay to *Lerici*.

Sixth Day. This would bring the tourist to Pisa, one of Italy's most attractive cities. The *Campo Santo*, with exquisite monuments and quaint frescoes extolled by Ruskin. The wonderful white and black marble *Cathedral*, *Leaning Tower*, and *Baptistery*.

Seventh Day. Two days at least would have to be devoted to Florence. The *Cathedral*, with glorious façade of coloured marble. The famous *Baptistery*, with the bronze doors called the Gates of Paradise. Giotto's *Marble Tower*. The *Uffizi Palace*, with picture gallery containing many gems of art, including Titian's "Venus of Urbino," Raphael's "St. John," Durer's "Adoration of the Magi," etc.

EIGHTH DAY. On the second day in Florence visit the *Lung' Arno*, and walk in the *Cascine Gardens*. The Churches of *Santa Maria Novella* and *San Marco*. The *Monastery* of San Marco, with the famous paintings in the cells, by Fra Angelico, and the memorials of Savonarola. The *Pitti Palace*, with the world-famous picture gallery, containing superlative gems by the greatest masters.

NINTH DAY. One would now come to SIENA. The black and white marble *Cathedral*, full of famous mediæval wonders. The pavement pictures on marble are the most famous of the kind in existence. The façade is of indescribable beauty. Siena is the most beautiful of all the "hill cities" of Italy. The *Church of San Domenico*, with the lovely chapel of St. Catherine. The *House of St. Catherine*. The *Palazzo Communale*.

TENTH DAY. Spend at ORVIETO, magnificently situated on a crag in the Apennines. The *Cathedral*, in black and white marble, almost rivals that of Siena, with its glorious façade and majestic nave. The famous well with two staircases, lined with maidenhair.

ELEVENTH DAY. In two days many of the chief glories of ROME may be seen. The visitor who cannot stay longer should proceed thus the first day: *St. Peter's Cathedral*, the dome, the "Pietà," by Michael Angelo, the chair of St. Peter, the Confessio, with 89 ever-burning lamps, the Jubilee Door, in mosaic, etc. The *Vatican Palace*, the largest in the world, and the home of the Popes. Here is the celebrated *Sistine Chapel*, with the wonderful ceiling by Michael Angelo, and frescoes by great masters; and also the world-famed Raphael Rooms. The *Church of St. John Lateran*. The *Holy Staircase*. The *Church of St. Maria Maggiore*. The *Church of St. Paul Without the Walls*.

TWELFTH DAY. The second day in Rome should be given to the *Forum*, with its extraordinary excavations showing the central features of Ancient Rome; to the *Arch of Titus*, on which is sculptured the triumphal entry into Rome with the spoils of Jerusalem; the *Arch of Septimus Severus*; the *Baths of Caracalla*; *Trajan's Column*; and the majestic *Coliseum*.

THIRTEENTH DAY. At LEGHORN. The picturesque *Harbour*, with its views of Elba, Gorgona, and Capraja. The *Giardino dei Bagni*. The *Corso*, with its coral and mosaic shops. The colossal statues of *Carlo Alberto and Ferdinand III*.

FOURTEENTH DAY. The last day would be spent at TURIN. This city is the capital and crown of Piedmont. The noble *Superga Cathedral*, on a lofty hill outside the city, is the burial-place of the Princes of the House of Savoy. The grand, wide streets of Turin, the fine statues, the splendid shops, and the picturesque piazzas make a visit as interesting as it is delightful.

A Tour of Three Weeks. This would enable the visitor to Italy to enjoy an extension of his tour either to the other lakes—Garda, Maggiore, Orta and Lugano—or to the cities of Verona, Padua, and Venice. The former would take him into the scenes of the greatest beauty, while the latter would be of incomparable interest. The former is replete with everything that could delight the eye of the artist. The latter appeals to the classic student with irresistible charm.

A Tour of a Month. If at all possible, a month should be spent in Italy, and this would enable the traveller to include both extensions. Or he might choose one of them, either the lakes or the cities, for a week, and then spend the fourth week in Naples, taking in Capri, Pompeii, Sorrento, Pæstum, Amalfi, and Salerno. *Five* weeks would be ample for both the above extensions, and also this enchanting excursion to the South. *A sixth* week would make it easy to see [illegible] of Sicily, taking in Palermo, Messina, Taormina, Catania, and Syracuse. Those who can afford the time and the money may thus in six weeks traverse the whole length of Italy, and become acquainted with many of its fairest and most romantic scenes.

Expenses. The expense of Italian travel is not at all extravagant. The tourist should reckon that on an average he will require at least 15s. a day for travel and hotel expenses. If he chooses the finest hotels in Rome he will, of course, find his bills considerably heavier. But in the small towns the charges are often exceedingly moderate, and the distances from town to town are short if a single district be chosen. Besides the expense thus indicated is to be reckoned the fare from London to Milan: First class, single, £6 3s. 7d.; return £10 0s. 7d. Second class, single, £4 7s.; return, £7 2s 8d.

In no country is travel now made more comfortable than in Italy. All the cities of any size are well provided with tramways. Steam and electric roads connect the suburban towns with the larger cities. Cabs are cheaper in Italy than in either our own country or France. A cab with a single horse costs 1 franc a course by day, and a franc and a half by night.

Food. Food in Italy has some peculiarities. The coffee is almost universally largely mixed with chicory, but the decoction is very wholesome and is well prepared. The bread is everywhere of very good quality. "Macaroni con pomidoro" is a very popular and most delicious dish. It is a preparation of macaroni with tomatoes. Olive oil is used in countless articles of diet, and so are onions and garlic.

Books to Read. The entertaining literature on Italian travel is voluminous. We recommend the intending tourist to read Villari's "Here and There in Italy," Pennell's "Italian Pilgrimage," Hare's "Cities of Italy," Macquoid's "Pictures in Umbria," Egerton's "Hill Cities of Italy," Macmillan's "Roman Mosaics," Marion Crawford's "Ave Roma Immortalis," Ruskin's "Mornings in Florence," Mrs. Oliphant's "Makers of Florence," D. Pidgeon's "Venice," W. D. Howells' "Venetian Studies," A. J. C. Hare's "Walks in Rome," Dr. Alexander Robertson's "Bible of St. Mark's," Villari's "Italian Life," Mrs. King's "Italian Highways," etc.

FARADAY'S ELECTRICAL RESEARCHES

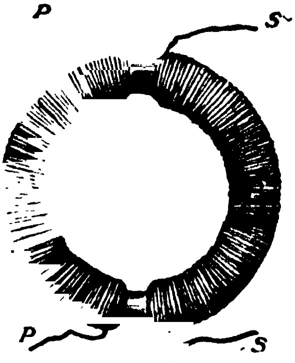
Group 10
ELECTRICITY
7

Continued from page [illegible]

Induction. Faraday's Ring the First Transformer. Attempt to Convert Magnetism into Electricity. Faraday's Primitive Dynamo

By Professor SILVANUS P. THOMPSON

Faraday's Researches. To Michael Faraday (1791–1867) more than to any other of the pioneers of electricity are electrical engineers, and, indeed, the whole world, indebted for the discoveries upon which the advances of modern times and the inventions of recent years are based. The chief discoveries which he made in electromagnetism, the foundation principles of all transformers and of all dynamos, were made in the autumn of 1831, the first fruits of his resolve to abandon the lucrative work of a professional expert in order to devote himself to scientific research. He had indeed already achieved fame by earlier researches, chief among them being the discovery of the electromagnetic rotations—the principle, in short, of electric motors—the chemical discovery of benzol and the liquefaction of chlorine. But it remained to him to discover, what had long eluded the grasp of the scientific experimenter—namely, the use of magnetism to generate currents of electricity. For at that date the only known ways of generating electric currents were (1) the chemical method in the voltaic cell, (2) the thermal method by the heating of the junctions of different metals, (3) the frictional method, as in the old glass electric machines. The first of these depended upon the consumption of zinc and acids in batteries; the second yielded very small electromotive forces, and was uneconomical; the third gave sparks and discharges rather than useful currents, and was unpractical. To these three Faraday added a fourth when he found that an electric current was generated in a copper conductor, mechanically, when the conductor was moved past the pole of a magnet, or when the magnet was moved near the conductor. Incidentally he discovered a great deal more than this; but the main point is that stated. For if we had had to depend on chemical action, thermal action, or friction, for our supplies of electric current, there would have been to-day neither electric light nor electric motive power. The public supply of electricity from central stations, and all the thousand applications in electrical engineering would have been quite out of the question.



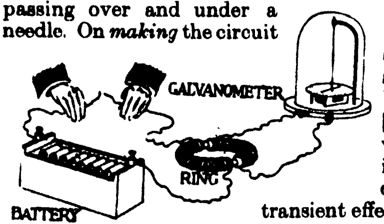
87. FARADAY'S RING

Induction. In the earlier-discovered phenomena of electricity the only known ways of producing a current in a copper wire had been by contact or conduction—the current could be conducted from one piece of metal to another. Also it was known that magnetism could be conducted along an iron bar by placing it in contact with the pole of a magnet. Conduction along the metallic substance from particle to particle was a familiar idea. It had also been known for half a century that an electric charge could be acquired by a body *by influence* from a pre-existing charge of electricity in another body, at a distance of a few inches apart, without any contact or communication between the two. To this phenomenon of action at a distance, discovered by John Canton, the name of *induction* had been given, to distinguish it from conduction. It was also known that magnetism could be imported, by influence, from a magnet to a neighbouring piece of iron without contact or conduction, and this was similarly called magnetic *induction*. But though one charge might induce another charge, and one magnet might induce another magnet, no one had ever been able to make an electric current induce another electric current, nor had anyone succeeded in causing a magnet to induce a current. Many philosophers had expected that some such relations would exist. They had tried to observe them experimentally. Faraday himself had both expected and experimented. In 1822 he wrote in his note book as a thing to be tried: "Convert magnetism into electricity." A splendid problem—but how to do it? In 1825 he tried several times, but without result, and again in 1828, for the fourth time, but fruitlessly. But in August, 1831, he began a systematic research, from which in a brief ten days of work, with intervals of contemplation and preparation between them, he emerged triumphant.

Induction from Wire to Wire. The idea, suggested by analogy, was that if there were two wires lying side by side, and if along one of them a powerful enough current were flowing, there would be some current induced in the neighbouring wire; but no experimenter, not even Faraday himself, had been able to observe such a thing. Again, it had been argued, by analogy (but incorrectly), that if an electric current circulating around a coil of wire, placed so as to surround a bar of iron could make that bar into a magnet (see page 562), then, as a deduction, if we were to put a powerful enough steel magnet inside such a coil of copper wire, the magnet ought to induce a current of electricity in the coil. But it did not when the experiment was tried. How to convert magnetism into electricity still remained a problem.

When Faraday set to work he began by coiling wires round wooden rods and wooden blocks; two wires, not touching one another, being carefully coiled side by side so as to lie close beside one another. He joined up one wire to a battery so that a current flowed along it. Then, joining up a galvanometer to the second wire, he looked to see whether any trace of current was "induced" in the second wire by the influence of the current in the first wire—and there was none. He varied the experiment in several ways, but obtained no success beyond a faint disturbance in the galvanometer, which occurred only if the galvanometer wire was joined up first, and the connection of the other wire to the battery was made afterwards; and then the disturbance was only momentary, at the instant when the battery connection was made or broken. As to any feeble current such as he had expected there was none. But the faint disturbance was a hint not lost on so keen an observer. It showed him that he must look for a transient effect, and to observe it the better he constructed new apparatus. This was tried on August 29th, 1831.

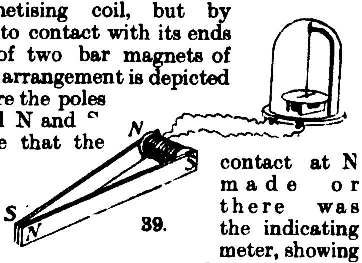
Faraday's Ring. Faraday had made a ring [87] of soft iron. It was forged by a blacksmith of iron rod ⅞ inch in thickness, and was 6 in. in external diameter. On this ring were wound two coils (A and B) of insulated copper wire; there being 72 feet in coil A, and 60 feet in coil B. This ring was used as follows. A battery of ten small cells was prepared to be connected to coil A, while coil B was joined to a simple galvanometer made of a coil of wire passing over and under a compass needle. On *making* the circuit between coil A and the battery [38] there was an immediate and transient effect on the galvanometer in the B circuit; its needle was deflected, oscillated, and finally settled down in its original position. On *breaking* the connection with the battery, the galvanometer again showed a temporary disturbance, but the deflexion was in the direction opposite to that of the deflexion which occurred on making the circuit. As the two coils A and B were quite separate, electrically, from one another, it was clear that the current in A had *induced* currents in the coil. It was also clear that the iron ring had a share in the operation. In fact, when the current in A was turned on, the circulation of the current in the A coils had magnetised the ring; and when the current in A was turned off, the iron ring had ceased to be a magnet.



38.

The magnetism of the iron core had obviously acted on the coil B, and had inductively generated currents in it.

Induction by Steel Magnets. On the third day of the experiments Faraday varied the plan of experimenting as follows. He had seen that in the ring experiment the magnetism made by coil A was evidently the agent which acted on the coil B; and he tested the matter by changing the apparatus so as to use the magnetism of common magnets of steel instead of the coil A, which, with its part of the ring core, had acted as an electromagnet. Accordingly, he connected the galvanometer by wires to a new B-coil not wound on a ring, but wound on a short cylinder of soft iron; and magnetism was imparted to this core not by any magnetising coil, but by bringing into contact with its ends the poles of two bar magnets of steel. The arrangement is depicted in 39, where the poles are marked N and S Every time that the magnetic contact at N or S was made or broken, there was motion in the indicating galvanometer, showing the presence of transient induced currents in the coil. Hence, as Faraday records, here was a distinct evolution of electricity by the aid of magnetism.

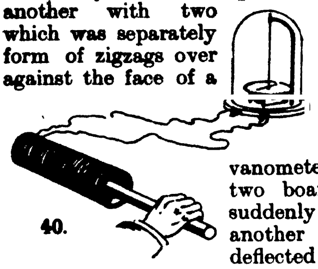


39.

Motion Essential. The circumstance that these effects were transient, and that no current, not even the feeblest, was generated while the magnets remained in contact, explained the failure of so many previous attempts. The missing factor in all the futile attempts had been motion, or what was its equivalent, change in the magnetic state. The magnet *at rest*, or the electric current flowing with uniform intensity, produced *no inductive action* on the neighbouring copper wire. The magnet must move, or it induced no current. The current in coil A of the ring must equally not be a current at rest; it must be a current that is growing in strength, or a current that is in the act of dying, if it is to act inductively; for it is only while the current is changing its strength that the magnetism due to it undergoes change.

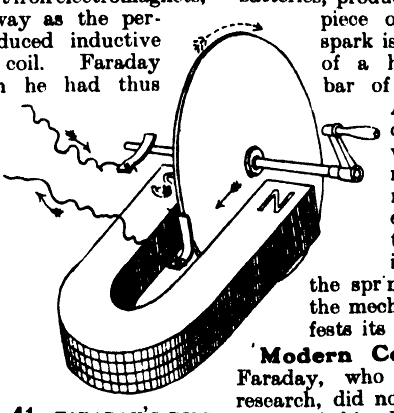
Movement of the Magnet. On the fifth day Faraday used a hollow cylindrical coil made by coiling 220 feet of wire around a pasteboard tube. This coil was joined up to the galvanometer. He then took a cylindrical bar magnet of steel 8½ in. long, and ¾ in. thick. On plunging it [40] into the coil the galvanometer needle made a quick movement to one side, and then returned to its zero. On pulling the magnet out, the needle again moved, but in the opposite direction. Here, evidently, an electromotive impulse was *induced* by mere approximation of the magnet, and not, as in the case of the iron ring, by formation of the magnetism in the stationary iron. Further, as the magnet used in the operation lost none of its magnetism during use, the energy which propelled the current must have been derived from the movement of the arm. It was the *mechanical generation* of a current by the expenditure of energy rather than any conversion of magnetism into electricity.

Faraday followed up this experiment by another with two coils, each of which was separately stretched in the form of zigzags over wooden pegs against the face of a board. The A coil was joined to a battery, the B coil to a galvanometer. When the two boards were moved suddenly towards one another the needle was deflected; when they were moved asunder the needle was deflected in the opposite direction. Soft iron electromagnets, when used in the same way as the permanent magnets, also produced inductive effects in a neighbouring coil. Faraday christened the phenomenon he had thus discovered by the name of *magneto-electric induction.*



40.

Faraday's Primitive Dynamo. On the ninth day of Faraday's experiments he was able to construct a "new electrical machine." Borrowing the most powerful compound magnet he could procure, he affixed to its poles, in order to concentrate its magnetism, two pole-pieces of iron set about ½ in. apart. Into this polar gap, where the magnetic field was strongest, he introduced a wheel or disc of copper, 12 in. in diameter and ⅕ in. thick, fixed on a brass axis mounted in frames so that it could be revolved. Against the edge and axis of this revolving disc he pressed collectors of springy metal, and these he connected by wires to the galvanometer. Fig. 41 shows the apparatus. On revolving the disc by hand a current was continuously generated, which produced in the galvanometer a steady deflexion. The direction of this deflection was reversed when the direction of rotation was reversed. "Here, therefore," he records, "was demonstrated the production of a permanent current of electricity by ordinary magnets."



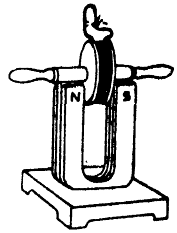
41. FARADAY'S DISC DYNAMO

This was the first primitive *dynamo.* The name, however, of *dynamo-electric machine* was not used till 1867, when Brooke coined it to connote all such machines. "A dynamo-electric machine will be one in which dynamic energy is employed to produce an electric current."

Faraday further pointed out the important part in all these experiments and apparatus played by the invisible *magnetic lines* (p. 560) of the magnets. He showed that in order to create any of these inductive effects the copper conductors must so move as to cut across the magnetic lines, or else the magnets or magnetic lines must so move as to "cut" by the copper conductors. In fact, the induced electromotive force is proportional to the number of magnetic lines cut per second.

Spark from a Magnet. In these splendid ten days Faraday had harvested a crop of new facts, new relations, and new principles, destined to immense development. He did not rest till he had shown that these induced currents could, like the currents from batteries, produce sparks and shocks. A simple piece of apparatus for generating a spark is depicted in 42. On the poles of a horse-shoe magnet rests a short bar of iron, provided with handles. Around the bar is wound a coil of wire, one of the ends of which is connected to a spring, making contact lightly against a metal button joined to the other end. On suddenly snatching this coil off the magnet a current is generated in the coil, and as the spring chatters at its contact with the mechanical shock, the current manifests its presence by a tiny spark.

Modern Commercial Development. Faraday, who devoted himself to pioneer research, did not push the commercial applications of his discoveries. "I have no time to make money," he explained. He ended this epoch-making research with the memorable words: "I have rather, however, been desirous of discovering new facts and new relations dependent on magneto-electric induction, than of exalting the force of those already obtained; being assured that the latter would find their full development hereafter."



42. FARADAY'S SPARK APPARATUS

That "full development hereafter" we see in the thousands of dynamos, alternators, magneto-generators, motors and transformers which furnish light and power by electricity for the use of mankind all the world over. It was the self-denying genius of Faraday which made them possible.

CIRCULATION OF THE BLOOD

Characteristics and Use of Blood. Its Composition. Function of the Corpuscles. Blood-vessels and their Work. The Heart and its Action

By Dr. A. T. SCHOFIELD

JUST as beneath our streets are three sets of pipes conveying gas, water, and sewage, so throughout the body are three descriptions of vessels coloured, by the fluid within them, red, white, and blue. The red vessels convey arterial blood from the heart; the blue return venous blood to the heart; and the lymphatics convey the drainage of the body cells into the venous blood near the heart, together with the digested fat from the food. These three sets of pipes are very numerous, and present many complications, which we will consider presently. Our first business is to examine the blood which flows through the vessels, then to consider the vessels, and lastly, to describe the heart that pumps the blood throughout the body.

The Blood—the Life of the Body. All the life of the body depends upon the quality and regular circulation of the blood. Our thoughts, our powers, our actions, depend upon its regular supply in proper quantity and quality to every part and every organ of the body. The brain is particularly sensible to any failure in the blood supply, and special arrangements are made there that nothing may interfere with its circulation. The blood, then, is a *heavy*, *red*, *opaque*, *warm*, *alkaline*, *saltish* fluid, with sometimes a faint odour characteristic of the animal to which it belongs. It is emphatically a living fluid, not only in the sense that upon it, as we have said, depends the existence of the body, but because it is full of life. It is the sole means, as we have seen, by which the varied and complex products of digestion, on the one hand, and oxygen, on the other, are conveyed to all the tissues and to every body cell, there to be reduced to simple forms of a less complex nature, the force liberated in the process being partly used in the passive life of the cells, and partly in the various active phenomena. The blood is, therefore, with the aid of the lymph, the carrier between the digestive and respiratory organs, on the one hand, and the living body cells, on the other, the blood-vessels forming, at the same time, a complete warming apparatus for the body. Blood is *heavy* as compared with water, the one having a specific gravity of 1,000, the other of 1,056.

Colour and Heat of Blood. The *colour* of blood varies from bright scarlet to dark purple. In the *arteries*, and also whenever exposed to the air, it is bright red. Hence, it is bright red in the superficial capillaries just beneath the surface of the cheek, and wherever the skin is thin enough to receive oxygen from the air.

In the *veins* it varies from dark purple to red, getting brighter in proportion to the activity of the part or organ whence it comes. It also presents different colours, being red by reflected light, and green by transmitted light. The blood is opaque, owing to its being a mixture of solids and liquid.

The average *blood* heat near the surface of the body is 98·4° F., and is about the same in health in all temperatures, "warm-blooded" animals, as we have seen, having constant blood-heat, independent of their surroundings, in contradistinction to "cold-blooded" animals, whose blood is not necessarily "cold," but varies with the surrounding medium.

The temperature of the blood in the deeper vessels is said to range between 100° and 107°. Its temperature is also increased in passing through large glands, notably the liver.

The blood is *alkaline* in life, but out of the body it soon becomes neutral, and then acid. It is saltish from the presence of common salt.

The *quantity* of the blood may be taken as about one-thirteenth of the weight of the body, a quarter of which is contained in the heart, lungs, and larger vessels; a quarter in the liver and its vessels; a quarter in the muscles, and a quarter in the circulatory vessels.

Composition of Blood. Blood consists, as we have said, of both a solid and a liquid. The solid part consists of small bodies called *corpuscles*, the liquid of a fluid called the *liquor sanguinis*, or *plasma*.

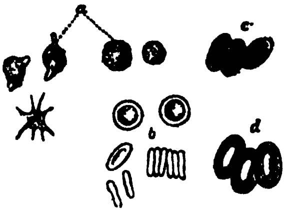
Two great varieties of blood corpuscles are generally recognised—the red and the white, or, more correctly, the colourless [39].

The blood is one-third solid, or corpuscles, and two-thirds liquid, or plasma.

The *red corpuscles* outnumber the white by about 500 to 1, and differ from them, not only in colour and size, but in being always round, which the white ones never are so, save in death. The red are about $\frac{1}{3200}$ of an inch in diameter, but are so numerous that it has been computed there are five million in every cubic millimetre (less than $\frac{1}{25}$ in.), and that the corpuscles in a man, spread out flat, would cover and colour red a space something like 30 square miles. They are round and biconcave, or discoid, that is, thinner in the centre than at the sides. They are soft, flexible, and elastic, and can squeeze almost anywhere. When the blood is drawn or clotting, the red corpuscles have a great tendency to run together in rouleaux, like piles of coin.

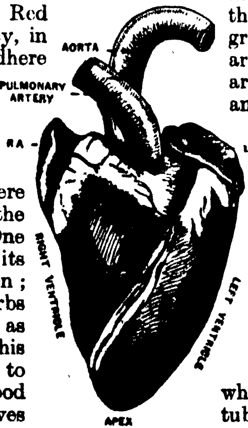
In fish and camels, these corpuscles are oval instead of being round; but there is no special distinction between human corpuscles and those of the higher animals, so that it is almost impossible to prove that a blood-stain is human.

175 Millions a Minute. Red corpuscles are quickly produced after severe loss of blood, and are said to be renewed at the rate of 175 million a minute. They are largely formed from the marrow in bones, in the spleen, and elsewhere; they differ from body cells in their shape, having no visible nucleus or central part that is darker than the rest. They are 60 per cent. water. Their average length of life is two weeks, during which they are filled with oxygen in the lungs, and emptied in the tissues some 20,000 times. They are destroyed chiefly in the liver, where they help to form the bile. Thus, in the body, nothing is wasted.



39. VARIOUS BLOOD CORPUSCLES
a. Human white blood corpuscles, some with processes. *b*. Human red blood corpuscles. *c*. Oval blood corpuscles of bird. *d*. Blood corpuscles of a frog

The red corpuscle is composed of a framework of protoplasm, holding in its meshwork a transparent viscid substance called *hæmoglobin*. It often swells up and becomes more or less spherical. It is exceedingly elastic, and more numerous in the male than in the female. Red corpuscles have a great tendency, in some conditions of the blood, to adhere together or change their shape. They are yellowish in colour, and only show the red tint of blood when seen in masses [40].



43. THE HEART
Showing the front external view with the aorta

Their numbers rapidly diminish in certain diseases. In anæmia there may be only one-fourth of the number present in health. One characteristic of hæmoglobin is its remarkable affinity for oxygen; owing to this the blood absorbs twelve times as much oxygen as water. The hæmoglobin holds this gas in a very loose form, so as to part with it readily. As the blood passes through the lungs it receives oxygen, and the hæmoglobin becomes an *oxyhæmoglobin*, as in arterial blood; then, again, as it reaches the tissues, the oxygen leaves it, and it is reduced to hæmoglobin. It is in this way that blood is the great oxygen carrier of the body. Hæmoglobin forms 90 per cent. of the bright red corpuscles. It is a crystalline body, and its one and special function seems to be to convey oxygen.

White Corpuscles. The colourless, or *white corpuscles* (discovered by Hensen, 1773), are larger than the red ($\frac{1}{2500}$ in. diameter), but are only spherical in death; during life their shape constantly varies [41]. Like the red corpuscles, they have no cell-walls, but, unlike them, they have one or more distinct nuclei. They have a finely granulated appearance, which, on examination under a higher power, is seen to be due to a meshwork that pervades them, the corners of the meshes being formed into knobs; part of the granules may be food material. The colourless corpuscles, or leucocytes, of the blood are identical with the smaller description of lymph cells that are found all over the body, and particularly in the spleen and lymphatic glands. The function of these cells has long been doubtful, and is only now beginning to be understood. They have very active habits during life. Possessing the power of traversing the walls of the blood-vessels with the greatest ease into the lymph space around, or into the body tissues, they are found in enormous numbers wherever any active inflammation is going on, and they form the principal part of pus or "matter."

Enemies of Bacteria. Professor Metschnikoff, of the Pasteur Institute, regards white corpuscles as our defenders against microbes of all sorts, and has lately shown how active they are in eating and destroying bacteria and germs, and also refuse of all kinds; while the curious fact has been discovered that from Peyer's patches in the intestine, where they abound, they migrate into the tube, seize on all the bacteria they can find, and carry them down into the deeper tissues, where they and their spoil both become the prey of a larger description of lymph corpuscle, called giant cells.

Enough has been said to show what a life of varied interest and usefulness white corpuscles lead, and to encourage us to hope for still further discoveries respecting them. They increase rapidly by fission, which the red corpuscles never do, and appear in amazing quantities in a very short time wherever they are wanted. The spleen is one great source of their origin, and in the splenic vein they number 1 to 80 of the red corpuscles.

The most remarkable feature about these corpuscles is their constant change of shape (which is

41. CORPUSCLES UNDER THE MICROSCOPE
Living white corpuscles changing shape under the microscope

always very irregular) by *amœboid* movements, so-called from their similarity to those of the *amœbæ* of stagnant waters. The great distinction between these and the red corpuscles is that the power of the former is distinctly vital; their change of shape is certainly of set purpose, as when they enclose a particle of food; they probably exercise, too, some distinct influence over the plasma, whereas the red corpuscles are merely oxygen carriers.

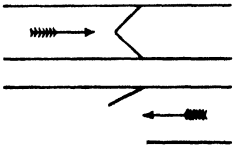
The Properties of Blood. The *plasma*, or liquid part of the blood, is nine-tenths water, is of a yellowish colour, and contains carbonic acid gas, albumen, fats, glycogen (liver sugar), and salts.

It has, because of other bodies contained in it, a most remarkable power of *clotting* or coagulating — a process, indeed, on which our life depends. As will be seen in the section on ILL-HEALTH, there is a class of people in whom this clotting power is either wholly absent, or so feeble as to be useless, and these people are in imminent danger of bleeding to death, even if a tooth is extracted.



46. VALVES IN VEINS, OPEN AND CLOSED

Huxley gives the following simple experiment to demonstrate this power of clotting:

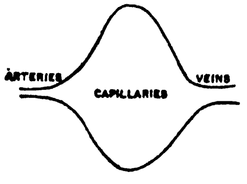
"Twist a piece of string pretty tightly round the middle of the last joint of the middle or ring finger of the left hand. The end of the finger will immediately swell a little, and become darker coloured, in consequence of the obstruction to the return of the blood in the veins caused by the ligature. When in this condition, if it be slightly pricked with a sharp, clean needle, a good-sized drop of blood will at once exude. Let it be deposited on a slip of thick glass, and covered lightly and gently with a piece of thin glass, so as to spread it out evenly in a thin layer. Let a second slide receive another drop, and to keep it from drying let it be put under an inverted wine-glass, with a bit of wet blotting-paper inside. Let a third drop be dealt with in the same way, a few granules of common salt being first added to the drop.

44. ARTERIAL AND VENOUS SYSTEM OF THE BODY

"To the naked eye the layer of blood upon the *first slide* will appear of a pale reddish colour, and quite clear and homogeneous; but, on examining it with a pocket lens, its apparent homogenity will disappear, and it will look like a mixture of excessively fine, yellowish-red particles like sand or dust, with a watery, almost colourless, fluid; and immediately after the blood is drawn, the particles will appear to be scattered very evenly through the fluid, but by degrees they aggregate into minute patches, and the layer of blood becomes more or less spotty."

48. NETWORK OF CAPILLARY BLOOD VESSELS

The particles are the red corpuscles of the blood; the nearly colourless fluid in which they are suspended is the plasma.



49. ARTERIES, CAPILLARIES, AND VEINS

50. RELATIVE SIZES
A. Capillaries. *B*. Arteries. *C*. Veins

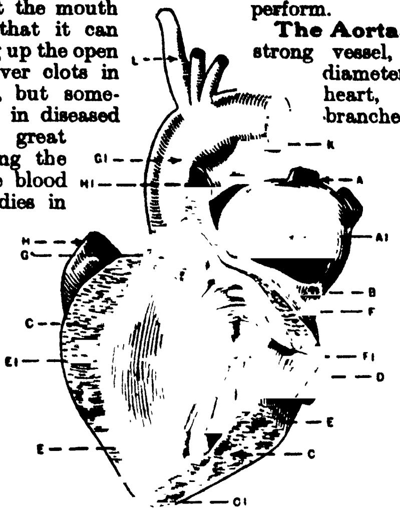
The *second slide*, prepared as described above, may now be examined. The drop of blood will be unaltered in form, and perhaps may seem to have undergone no change. But if the slide be inclined, it will be found that the drop no longer flows, and, indeed, the slide may be inverted without the disturbance of the drop, which has become solidified, and may be removed with the point of a penknife, as a gelatinous mass. The mass is quite soft and moist, so that this setting or *coagulation* of a drop of blood is something quite different from its drying.

On the *third slide* this process of coagulation will be found not to have taken place, the blood remaining a fluid as it was when it left the body. The salt, therefore, has prevented the coagulation of the blood. Thus this very simple investigation teaches that blood is composed of a nearly colourless plasma in which many coloured corpuscles are suspended, and that this coagulation may be prevented by artificial means, such as the addition of salt.

The coagulation is brought about by the changing of a part of the plasma into a branching mass of fibrous tissue called *fibrin*, in the meshes of which myriads of the red corpuscles are entangled.

Why Blood Clots. As the clot is thus formed, a thin straw-coloured fluid is squeezed out, called the *serum*, which is practically plasma deprived of its fibrin. The value of this clotting power is, of course, in its solidifying the blood at the mouth of a cut artery or vein, so that it can no longer flow, thus stopping up the open end of the vessel. Blood never clots in a healthy vessel during life, but sometimes the blood may clot in diseased veins, and thus become a great source of danger by blocking the circulation. Clotting in the blood is hastened by any solid bodies in the blood, by heat at 100° F., by being stationary, by the action of air, by deficiency of water, by injury or disease of vessels. It is deferred by increase of water, cold or great heat, by an alkaline solution (salt), and by being in living blood-vessels. Arterial blood clots more quickly than venous blood.

On the whole, blood has a similar chemical composition to that of muscle. The gases in the blood are as follow: *Oxygen*, 20 per cent. in arteries and 10 per cent. in veins, all carried in the red corpuscles; *carbonic acid gas* in arteries, and 47 per cent. in veins, all carried in the plasma; *nitrogen*, 1 or 2 per cent. vol.

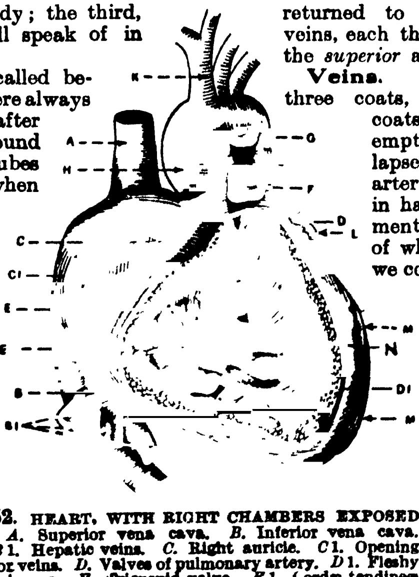


51. HEART, WITH LEFT CHAMBERS EXPOSED

Pulmonary artery. *K*. Attachment by ductus arteriosus to aorta. *L*. Arteries to head and arm

The Blood-vessels. We now turn to the blood-vessels, which include two out of the three sets of pipes in the body; the third, or the lymphatic, we shall speak of in the next chapter.

The *arteries* [42] are so called because by the ancients they were always supposed to contain air, as after death they were always found empty. They are stout tubes that remain round even when empty, and are made of three coats, the outer (the *adventitia*) being fibrous for protection, the middle (the *muscular*), to regulate the size of the vessel, and the inner one (the *intima*), a delicate membrane of living cells which have many active functions to perform, not least of which is to aid in removing impurities, germs and the like, from the blood. So that we must distinctly understand that there is nothing dead or mechanical about either the blood or blood-vessels. The former is filled with active living white corpuscles; the latter lined with many active living cells, which have definite work to perform.



52. HEART, WITH RIGHT CHAMBERS EXPOSED

Left ventricle. *N*. Right ventricle

The Aorta. The arteries begin in one strong vessel, the *aorta* [43], 1 in. in diameter, which, as it leaves the heart, soon subdivides into six branches—two for the head, two for the arms, and two for the legs. These divide and subdivide as they run along the protected inner sides [44] of the limbs and all over the body, like the branches of a tree, till the tiniest twigs are so small that they can hardly be seen by the naked eye, and these are called *arterioles*.

Arteries are elastic and, always being a little overfull, they are ever on the stretch, and so maintain that gentle pressure on the blood that keeps up the flow between the beats of the heart. When an artery ruptures, the inner coat folds over inwards as it contracts, and thus at once begins to stop the flow of blood.

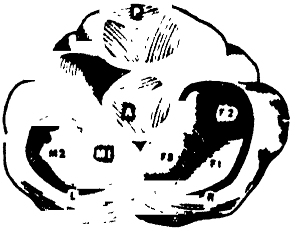
A short distance from the end of the *arterioles* the smallest *veinlets* begin, and rapidly uniting form large trunks which lie alongside of the arteries, until at last the united volume of blood is returned to the heart by two great veins, each the size of the aorta, called the *superior* and *inferior* vena cava.

Veins. *Veins*, like arteries, have three coats, but, unlike them, these coats are so thin that an empty vein flattens and collapses. They also differ from arteries, especially in the limbs, in having a remarkable arrangement of valves [45], the value of which will be apparent when we come to speak of the circulation. These valves are in pairs, an inch or so apart, and are made to open towards the heart, so as to afford no obstruction to the progress of the blood in that direction [46], but to close at once if it tries to turn back. The walls being thin, they more easily bulge under pressure than those of arteries.

Capillaries. Until 1661 this was all that was known of the blood-vessels, and it was believed

SALAR JUNG LIBRARY

that the blood was poured out into the tissues by the arteries, to be picked up a short distance off by the veins. It was then discovered, however, that between the two an intricate network of tiny microscopic blood-vessels (called *capillaries*) exists, some $\frac{1}{3000}$ of an inch in diameter [47] extending all over the body in such inconceivable numbers that it is almost impossible to insert the point of a pin anywhere without piercing one of them [48]. The whole body thus consists of tiny islets of cells surrounded by capillaries, which themselves lie in lymph channels. These tiny vessels have but one coat, but as we have fully described them and their remarkable functions in the last chapter, we need not recapitulate here. They extend to thousands of miles. If the arteries begin in one tube 1 in. in diameter, and the veins end in two tubes with a united calibre of 1½ in., the united calibre of the capillaries is represented by a tube of about 2 ft. in diameter [49].



53. VALVES OF THE HEART

A transverse section. *A.* Aorta. *P.* Pulmonary artery. *M* 1 & 2. Two flaps of mitral valve. *F* 1, 2, & 3. Flaps of tricuspid valve. *L.* Left side. *R.* Right side

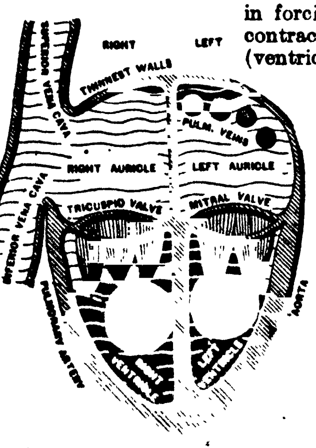
The Heart. We must now proceed to describe the mechanism by which the circulation of the blood is maintained by the elaborate pump called the heart.

The *heart*, enveloped in the double layer of the *pericardium*, is in the form of a blunt, hollow cone about the size of its owner's fist. It weighs about 9 oz., and is situated behind and somewhat to the left side of the lower half of the *sternum*, or breast-bone. Its base is uppermost and to the right, its apex being downwards and towards the left. It consists, like the arteries and veins, of three coats; an outer fibrous coat, called the pericardium, which really consists of two layers, forming a closed sac, the heart being folded up in it. The inner layer is closely adherent to the heart, and the outer layer to the connective tissue around, a small amount of fluid being between the two.

An illustration may help us to understand how the pericardium is arranged. Take two thin paper bags, of which one is slightly smaller than the other, so that one may be contained within the other, both being fully distended. Now slightly fold back the edge of the mouth of the inner bag, and gum it all round to the edge of the mouth of the outer one. There is now a double bag made with an inner and an outer layer, and a small space between them, completely shut off from the outside. Suppose the closed fist to be just large enough to fill the inner bag, it will represent the heart, to which the inner layer of the pericardium is adherent. The wrist will represent the great vessels passing off from the heart, around which the neck of the double bag extends. All the serous membranes which enclose the various organs are made on the same principle—around the brain, lungs, and digestive organs.

Muscles of the Heart. The *middle*, or muscular coat, forms the main substance of the heart itself, and in a muscular man varies from a quarter of an inch to an inch in thickness; while the *inner* coat is the lining membrane of the heart.

The muscle is peculiar, for the fibres are intermediate between the striped, or voluntary, muscles of the limbs and the unstriped, or involuntary muscles, of the arteries. They have transverse stripes and contract altogether like the former, but are not under the control of the will, thus resembling the latter. They are arranged in circular, oblique, longitudinal, and (towards the apex) in spiral layers. They continue for some distance along the two large veins. The fibres that surround the upper half of the heart are distinct, and can contract separately from those around the lower half. The muscular coat varies immensely in thickness. It is thinnest around the upper half of the heart on both sides (the auricles), because the work here is slight and only consists in forcing the blood, as the auricles contract, into the two lower cavities (ventricles). It is twice as thick on the lower right side, for this has to do twice as much work in pumping the blood through the lungs; and it is more than twice as thick again in the left lower half, because this ventricle has to pump the blood all over the body. The thickness of the muscle everywhere is in proportion to the amount of work it has to do.



54. DIAGRAM OF THE HEART

On right side two vessels enter and one leaves it. On left side four vessels enter and one leaves it

Chambers of the Heart. Inside, the heart in man is divided longitudinally into two halves, right and left; each half is again divided transversely, thus making four chambers in all [54]. In fish there are but two, in a frog three, while in the crocodile upwards, we get four. All these stages are passed through in the human embryo [51].

The two upper chambers are called respectively the right and left auricles, because on the top of each is a small flap like a dog's ear, and *auricula* means a little ear. They have very thin muscular walls. The two lower ones are called the right and left ventricles (*ventricula*, a little belly), and have much thicker walls; the left being also at least three times the strength of the right. Each chamber holds about four tablespoonfuls of blood. There is no direct communication between the right and the left side of the heart after fœtal life.

Trap-doors of the Heart. Each auricle communicates with the ventricle below by a sort of large trap-door in the floor, which on the right side consists of three flaps, and is called the *tricuspid valve*, and on the left of two and is called the *mitral* or *bicuspid valve*.

The right auricle has, in addition to this valve, the large opening (*sinus venosus*) common to the terminal veins [52].

In the right ventricle is the opening of the *pulmonary artery* which conveys the blood to the lungs to be purified, guarded by a *semilunar valve* which has three flaps. The centre of each margin has a little node (the *corpus arantii*), the three meeting when the valve closes. The bulging of the wall of the artery behind the valve is called the *sinus of Valsalva*. The parts in the aortic semilunar valves are similarly named. The left auricle has four openings for the four *pulmonary veins* that return the purified blood from the lung to the heart; and in the left ventricle is the large opening of the *aorta*, by which the blood finally leaves the heart, guarded by a *semilunar valve*, which has three flaps as in the right ventricle.

There are thus in the heart [53] three valves with three flaps (two semilunar and one tricuspid), and one with two flaps (the mitral). The arrangement of all these valves is such that the blood can only pass in one direction, always from the venæ cavæ towards the aorta. The orifices of the valve are strengthened by thick, fibrous rings, while the flaps of the tricuspid and mitral valves are stiffened and prevented from rising too far by strong bands (*musculi papillares*) and cords (*cordæ tendineæ*) fixed from the inner surface of the ventricle to their lower side. Fleshy pillars (*columnæ carneæ*), from which these cords spring, are also seen on the inner surface of the heart.

The two arteries (pulmonary and aorta) come from the front of the heart, while the six veins, two venæ cavæ and the four pulmonary veins, enter at the back. There are thus eight large blood-vessels connected with the heart, three with the right side and five with the left. On the right the two venæ cavæ returning blood from the body to the right auricle, and the pulmonary artery (the only one in the body conveying venous blood) carrying the blood from the right ventricle to the lungs. Then on the left the four pulmonary veins from the lungs enter the left auricle, and the aorta leaves from the left ventricle.

Action of the Heart. The heart contracts by nervous mechanism in the organ itself, and this is regulated by the brain. The heart muscle alone has a remarkable inherent contractile power, which is dependent on no external nervous energy nor even on the nerve centres in the heart, nor on blood in the heart. Contraction has been seen in bits of freed heart muscle, and appears to be absolutely *automatic*. No other muscle has this power, and there is no other muscle even in appearance like the heart muscle.

The heart as a whole, cut out from the body but supplied with blood, will beat for days. If supplied with oxygen instead of blood, for twelve hours; if with air, for three; if in a vacuum, for half an hour; if with CO_2, in each case it stops. There are in the heart three or more nervous centres from which undoubtedly energy is supplied; and bits of muscle containing them beat much more vigorously than those without.

Then besides this, the frequency of the contraction is regulated by two nerves. The one, the *pneumogastric*, slows the beat, and pressure on it may stop the heart altogether; the other, the *sympathetic*, accelerates it, and the influence of the emotions, causing the heart to beat more quickly under excitement, explains how that organ came to be regarded as the seat of the affections, with which it has really nothing to do.

The heart has no nerves of sensation, and hence it can feel nothing, and such a thing as pain *in* the heart is impossible. Even in angina, the only painful heart disease, the spasm is believed to be in the arteries and especially in those arteries (the coronary) that supply the walls of the heart itself with blood.

The heart on rare occasions is transposed and may be found beating on the right side of the body instead of the left. In disease it is frequently greatly enlarged.

continued from page 826

FRICTION & ITS APPLICATIONS

Theory and Laws of Friction. Mechanical Uses of Friction, including Brakes, Belt-hammers, Clutches, Gears, Shafting, Belts

By JOSEPH G. HORNER

Friction. No substance exists which has, or can have, a perfectly smooth surface. The polished face of a piece of wood or stone, or the surface of glass, is covered with minute roughnesses, although this unevenness is imperceptible to the senses of sight and touch. Thus, when two surfaces are in contact, the multitudinous protuberances interlock, resisting both the setting in motion and the continuance in motion of one surface over the other. This resistance is called friction. It destroys, but cannot generate motion, and it acts always in the contrary direction to that in which the body is moving.

How does the engineer regard friction ? Sometimes this force acts as a valuable ally in promoting the stability of a structure or in assisting the work of a machine, and it may even be necessary to assist this force in its tendency to resist slipping. To friction we are indebted for the action of the driving-wheels of locomotives, for they would otherwise slip on the rails and make no progress ; for the action of cords and straps round pulleys and drums ; for the gripping power of a vice ; for the arresting power of a brake ; and so on. Sometimes, however, friction is distinctly disadvantageous, and presents an obstruction to the efficient working of a machine. The ingenuity of engineers is then called into play to reduce its inimical tendency. Thus, roller and ball bearings assist the rotation of a shaft, while oils and tallow are extensively used as lubricants. Even then continual friction gradually abrades the hardest material, and so, in a machine where two parts are exposed to friction, that one which can be more easily or cheaply replaced is made of softer metal, so as to receive the greater degree of wear.

Kinds of Friction. The force tending to prevent the setting in motion of two bodies at rest is called *static friction*, and the resistance tending to arrest the motion of one body over another is *kinetic friction*. A distinction is also drawn between *rolling* friction, as in the revolution of a cart-wheel, and *sliding* friction, as in the motion of the same wheel going down hill with a skid on. It might be thought that the resistance between any two surfaces would be similar, whether they were at rest or in motion, but we shall see later on that this is not so. The word friction (Lat. *frico*—I rub), used in the statical sense, is scarcely exact, for there is no rubbing until motion commences.

How to Measure Friction—Coefficient of Friction. The amount of static or kinetic friction between any two bodies may be measured by a simple experiment. Suppose it is required to measure the frictional resistance between the weight W [**105**] and the surface A B along which it slides. The cord runs over a delicate pulley (C), and is attached to the scale pan. Weights (P) are gradually added until W starts moving. The weight required to do this measures the friction between the surfaces ; that is, P = the frictional resistance. In this experiment W = 10 lb., and P = 4 lb. Thus the ratio between the friction and the weight $\frac{P}{W}=\frac{4}{10}=\cdot 4$. This fraction is called the *coefficient of friction*, and if W and A B were composed of oak, then $\frac{4}{10}$ or ·4 would be spoken of as the coefficient of friction for oak on oak.

The coefficient obtained in this experiment should more correctly be termed the static coefficient, because P measures the greatest frictional resistance the bodies are capable of offering to a sliding force when at rest. If the surface (A B) is sufficiently long, it will be found that a *less* weight will be necessary to cause W to continue in uniform motion along A B if this steady motion is started with a slight push of the finger. In other words, static friction is greater than kinetic friction. A horse which has a difficulty in starting a heavy load pulls it with comparative ease once it is in motion. Actual experiment has shown that the static coefficient of dry wood on dry wood is ·50, but the kinetic coefficient is only ·36 ; similarly, the coefficient of dry wood on metal is ·60 at rest, but when in motion, ·42. If in this experiment the student substituted other substances and other surfaces, it would be found that a less weight or power would be required to start W in motion when the surfaces were smooth, and a greater power when the surfaces were rough. Hence, the fraction $\frac{P}{W}$ would become greater or less, according as the frictional resistance was greater or less. So we find that the coefficient of friction of wrought iron on oak is ·62, but that of steel on glass is ·11 ; of brick on brick ·64 ; but polished marble on polished marble ·16.

Another and simpler method of finding both static and kinetic coefficients is shown in **106**. W is the weight resting on a board (A B). One end of the board is very gradually raised until W slides down with uniform motion (for determination of kinetic friction), or until the weight is just about to start moving by itself (for static friction). When these points have been arrived at, then the ratio between the height and base of the plane gives the coefficient of friction. In the diagram the height is 8 and the base 30. Therefore the coefficient is $\frac{8}{30}$ or ·26.

Angle of Friction. In the last experiment the angle at A which the board makes with the horizontal surface A C is called the *angle of friction*, the *angle of repose*, or the *limiting angle of resistance*. As in the previous case, it will be found that this angle is less when the board is so inclined as to permit of steady and uniform motion of W than when the weight is about to start moving. The angle of friction may be described, then, as the angle made by a plane with a horizontal surface at the moment when a body that is placed on the inclined plane begins to slide. The amount of frictional resistance of any substance may thus be considered and stated, either as regards its angle of friction or its coefficient. Generally, both these relations are stated. The following are interesting examples:

Substances.	Coeff. of frict.	Ang. of frict. Deg.	Ang. of frict. Min.
Oak on elm, fibres parallel to motion	·25	14	3
Wrought iron on brass ..	·17	9	39
Steel on cast iron	·20	11	19
Brass on cast iron	·22	12	25
Hard on soft limestone ..	·67	33	50

Referring again to **106**, the student who has any knowledge of trigonometry will see that the coefficient $\frac{8}{30}$, or $\frac{BC}{AC}$ is the tangent of the angle [illegible] tangents. The coefficient of friction may therefore be stated in different ways, all having the same meaning. In **106** it is equivalent to $\frac{\text{height}}{\text{base}}$ or $\frac{\text{friction}}{\text{normal pressure}}$ or $\frac{\text{resistance}}{\text{normal pressure}}$ or tan A. This ratio is frequently represented by the Greek letter μ. If, then, F = frictional resistance, and R = normal pressure, $\frac{F}{R} = \mu$, and $F = \mu R$; *i.e.*, if R be known and multiplied by the coefficient of friction obtained from a table, the amount of friction between the two bodies may be determined. It will be noted that in the first experiment the coefficient of friction was stated as the ratio between the friction and the *weight*, and that now *normal pressure* is substituted for this term. By the normal, or perpendicular, pressure of a body is meant the amount of pressure acting *perpendicularly* to the surface on which it rests, and though this would be synonymous with the weight in **105**, it would not be so in **106**. The perpendicular pressure of a locomotive on a level track would be equal to its weight, but on a gradient the pressure acting perpendicularly to the rails would be less than the weight, and would continue to grow less as the slope increased.

Laws of Friction. Less than 80 years ago General Morin, of the French Army, discovered, after investigations lasting two or three years, certain fundamental laws governing friction. Though more delicate apparatus and more extensive experiments have shown that the universal application of these laws fails, yet they are sufficiently correct for all but extreme cases.

1. Friction is independent of the extent of the surfaces in contact.

2. The amount of friction is proportional to the pressure between the two surfaces in contact.

3. Friction is independent of the velocity with which one body moves over the other.

For ordinary pressures and velocities these laws are generally true, but are not correct for high velocities and extreme pressures. As velocity increases, the coefficient actually decreases, and vice versâ. Experiments with lubricated journals have shown that as the speed of revolution slowed down from 18 ft. per second to a stop the coefficient of friction gradually increased. Temperature is also an important factor. Several other laws or conditions have also been deduced from experiments.

4. Statical friction, or the friction of rest, is greater than kinetic friction, the friction of motion. This was proved in the experiments in the preceding paragraphs, and is illustrated when a child slides its mother's flat-iron down the washing-board.

5. Statical friction is increased after the two surfaces have been in contact some little time.

6. Rolling friction is less than sliding friction.

7. In rolling friction the resistance is proportional to the weight, and inversely proportional to the radius of the wheel.

[illegible] in overcoming [illegible] , or electricity.

Friction of Liquids. The laws just stated for solids do not apply to liquids. Investigations have so far failed to discover a coefficient of friction such as that for dry surfaces. Apparently, frictional resistance is proportional to the area of the surface of contact. At low velocities resistance is small, and probably = speed × area of surface × a coefficient, but at and above a certain critical speed the formation of counter currents increases resistance, so that speed in the above equation has to be squared. The resistance is largely independent of the material composing the solid body with which it is in contact, and it is also independent of the pressure to which the fluid is subjected.

PRACTICAL APPLICATIONS

The applications of the foregoing may divide themselves naturally under two heads—that in which the endeavour is made to utilise friction, and that where the object sought is to reduce it as far as possible. Each, therefore, involves entirely opposite sets of conditions, and each has an immense number of applications in practice.

Brakes. Taking the first group named, we see friction utilised in brakes, in clutch connections, and in certain forms of gears for transmission of power. A common example of brake friction was illustrated in connection with the lever in the last article. The coefficient of friction, combined with the very large arc of contact between the brake strap and its band pulley is so high that such brakes are capable of sustaining weights as high as 8 to 10 tons by their friction alone. This is regularly utilised in cranes, in which the reversal of the crane movements is avoided by "lowering with the brake." That means, of course, not that the brake does the lowering, but that the weight of the load is the agent, and the brake regulates the rate of, and checks, the descent at the right instant. Thus, 107 shows a brake (A), a drum (B), and barrel wheel (C), all on the same shaft. The load is hoisted on B by the wheel C, actuated by a pinion, but it is lowered by *braking* on A. What this means in economy of time and labour may not be apparent on first thoughts. But imagine, in a hand crane, the slow and fatiguing movement of turning the winch handles and slow gears to lower a load. Or, in a power crane, consider the useless running and rattling of gears in engagement by comparison with the swift descent of the load by its own weight. The band-brake is used also in winding and hoisting machinery employed in mines for controlling the descent of cages and skips. In light mechanisms the same device is employed to bring rapidly rotating parts to rest in order to save time or to avoid danger. The most familiar is the cycle brake.

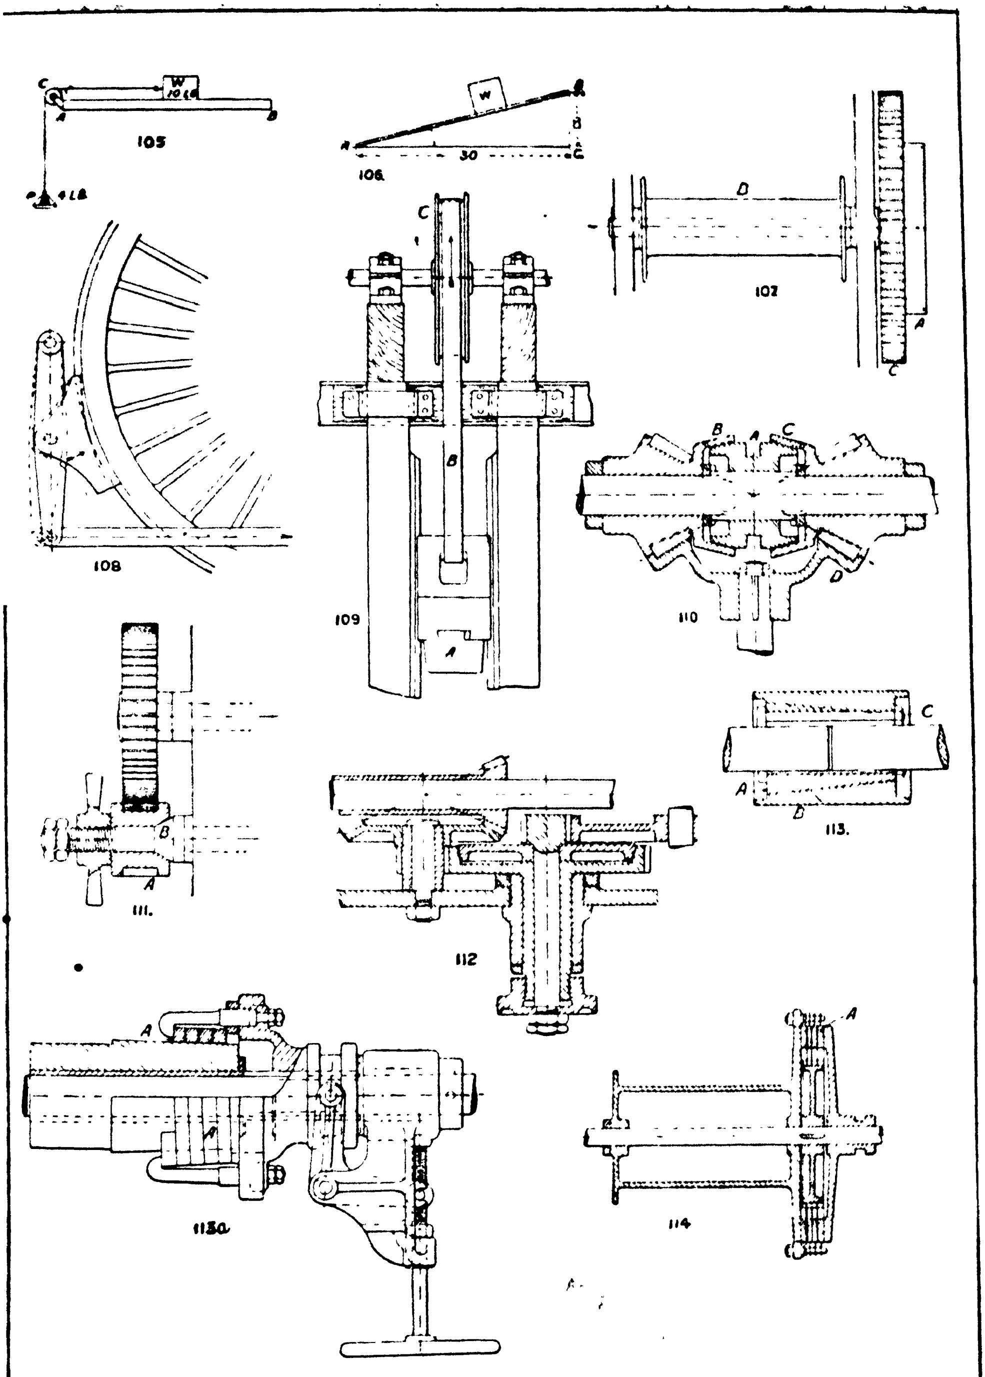
Brakes need not make large arcs of contact as the flexible bands do. There are many rigid slipper brakes used, operating on comparatively short lengths or arcs. When the turner presses his hands upon the driving pulley of his lathe to bring it rapidly to rest, his hand is applied as a friction brake. The big tramcars are arrested by slipper brakes pressing upon the rails. Railway trains are brought to rest by the pressure of wooden or metallic brake-blocks pressing on a small portion of the circumference of the wheels [108]. But there is enormous pressure behind them, produced by vacuum or steam-pressure agency.

Belt-hammers. Fig. 109 shows a friction device that may be seen in hundreds of smithies to-day—the drop hammer. Only the upper portion is illustrated, as with that alone we are concerned. The tup, or hammer head (A), which delivers the blows on forgings or dies, is lifted by the frictional contact of the leather belt (B), around the smooth iron pulley wheel (C), rotated constantly by shafting. The workman puts on the friction by pulling at the free end of the belt and letting it go when the tup has been sufficiently raised. As long as he keeps his hand on the belt, the latter makes contact round an arc of 180° with the revolving pulley, and the latter lifts the belt and its tup by friction. The illustration shows the tup at its full height. On releasing his hand the tup falls instantly, and so he adjusts the height for such blows as the work requires—light or heavy, slow or rapid—by simply and instinctively varying the pull of the hand and thence the friction of the belt.

Clutches. An immense group of friction mechanisms are the clutches, by means of which rapid connection and disconnection is made between moving parts of mechanism. A whole line of shop-shafting driving to numerous machines can be set rotating by the movement through a lever or hand wheel of a comparatively tiny clutch, making connection between it and the source of power, engine or electric motor. It can be instantly disconnected by throwing out the clutch. Friction alone is the agency by which the powerful engagement is made. The mechanism is of high value not only on account of its efficiency, but also because of its rapid character. Should an accident occur, it is not necessary to stop the engine, which takes some time, but simply to disconnect the clutch. In hoisting-machinery the same mechanism is frequently employed for throwing the different motions into and out of action. You do not stop the engine or electric motor, but throw the clutch in and out, so making and breaking connection with the various motions.

Further, the clutch arrangements are so designed that reversals of motion are effected without altering the direction of motion of the engines. The same design occurs over and over again in many groups of machines and machine tools. It comprises simply [110] a double-clutch (A), sliding and moved by means of a lever to right or left to engage with corresponding reverse clutches (B C), cast with bevel wheels, both of which engage with one crown wheel (D), so that the shaft rotating in one direction is made always to turn the crown wheel and its shaft in either one of two directions, according as the clutch is slid to right or left. These *cone clutches*, as they are termed, are used for both light and heavy machinery. Given sufficient frictional area, which is obtained by increasing the diameter and width, they are capable of sustaining the heaviest loads that are ever required to be operated.

Cone friction is also employed on many machine tools for the purpose of starting and maintaining movements of parts. It is in the form of the cone clutch (friction feed) [111 and 112]. No great effort is required on the part of the attendant, but the simple turning of a cross handle [111] or a knob [112] puts it in and out of engagement. In 111 the pinion (A), normally running loosely on its shaft (B) is tightened thereon by pressure against the coned neck, and then drives, or is driven, by the wheel with which it is in mesh. In 112 the cones are of large size, drawn in by the knob and screw to traverse a lathe carriage through spur and bevel gears and rack (not shown). Fig. 113 represents a cone coupling for shafts. It is often made with two reverse cones. The cone is tightened round the shaft ends by friction grip obtained by drawing the split cone (A) along its sleeve (B,) by the bolts (C), which are three in number. There is not much range in the useful angle for proper frictional grip in the foregoing figures. If too high an angle is given, slip will occur; if too low, seizing of the parts. In other words, the clutch surfaces will stick together so that they cannot be separated. The drawings are to scale from actual mechanisms. The surfaces in contact are turned to templet, to make a perfect fit. No lubricant must come between them. Iron and iron are generally used in contact. Steel is not satisfactory, being liable



EXAMPLES OF FRICTIONAL DEVICES

to seize, and as steel is often used for clutches, one is then properly lined with copper, which grips well with its fellow of steel without seizing.

Coil Clutches. A successful device for doing away with the rigidity of the common cone clutch is the coil clutch [118a] of the Consolidated Engineering Co., Ltd., of Slough. It substitutes an elastic frictional medium (the coil A), which, being forced endwise, contracts and grips the inner cone. The coning is very small in amount. It is instant in action, and requires little power to hold it in place. It amounts practically to a split cone, to which, however, it is preferable. No better proof of the efficiency of these can be given than the fact that they are in some cases used for transmitting as high as 1,500-horse power. Pressure is brought to bear on the coil by any convenient means, as by the hand wheel, screw, and levers in the illustration.

But a friction clutch need not be coned. It may have flat faces, as in the Weston clutch [114] and modifications of it. Here discs of hard wood (A) as originally used are pressed into close frictional contact over their entire surfaces, and the grip is enormous. At present discs of steel and bronze have been substituted for wood, as they are more durable

Sellers' Discs. Another form of friction drive used to a large extent for nearly twenty-five years past is the Sellers' discs [115]. Two discs (A A), having a slight capacity for adjustment towards and away from each other, embrace, or are released from contact with other discs (B and C) by a carefully graduated spring pressure acting on the globular boss seatings of A A. Motion is thus transmitted from the toothed gear adjacent, to B, through A A to C, by the simple frictional contact of the discs, and the lathe feed is thus actuated. This device, of course, also embodies provision, though not shown, for varying the rates of revolution between the driver (B), and the driven (C). A lever moves the centres of A A horizontally in relation to B and C, and thus produces engagement between the discs at varying radii, with consequent varying rates of relative speed, since the discs A A are capable of gripping B C at any radius. There is another common device—the bowl feed [116], in which a smooth-faced wheel (A) (the bowl) is driven by contact with the flat face of a disc (B) at varying rates. The variation is produced by altering the radius at which the bowl makes contact.

Expanding Clutches. In another common form of transmitting-mechanism the friction is that of plain cylindrical surfaces. As these cannot be slid into and out of engagement like the coned form, the inner ring (A) [117] is divided in the radial direction, to render it elastic (an expanding clutch), and a wedge (B) is used to force it open sufficiently to make frictional contact with the outer casing. The wedge is actuated by a key (C), thrust along by a cone (D), also an example of wedge friction. Clutches of this general type in various modifications are used in hoisting-machinery, and in capstan lathes for the rapid throwing in and out of the back gears.

Expanding clutch rings are operated in various ways, one successful type, Heywood & Bridge's, being shown in 118. The ring (A) in halves is thrust outwards to make frictional contact with the outer solid ring by sliding the clutch boss (B) on its shaft, and with it the toggle levers (C). The action is to turn screws of quick pitch on the pins (*a a*), which force the half rings outwards away from each other simultaneously. The hand wheel (D) is the means by which the movements are effected, but this is a variable element, which differs in the numerous applications of the essential clutch mechanisms.

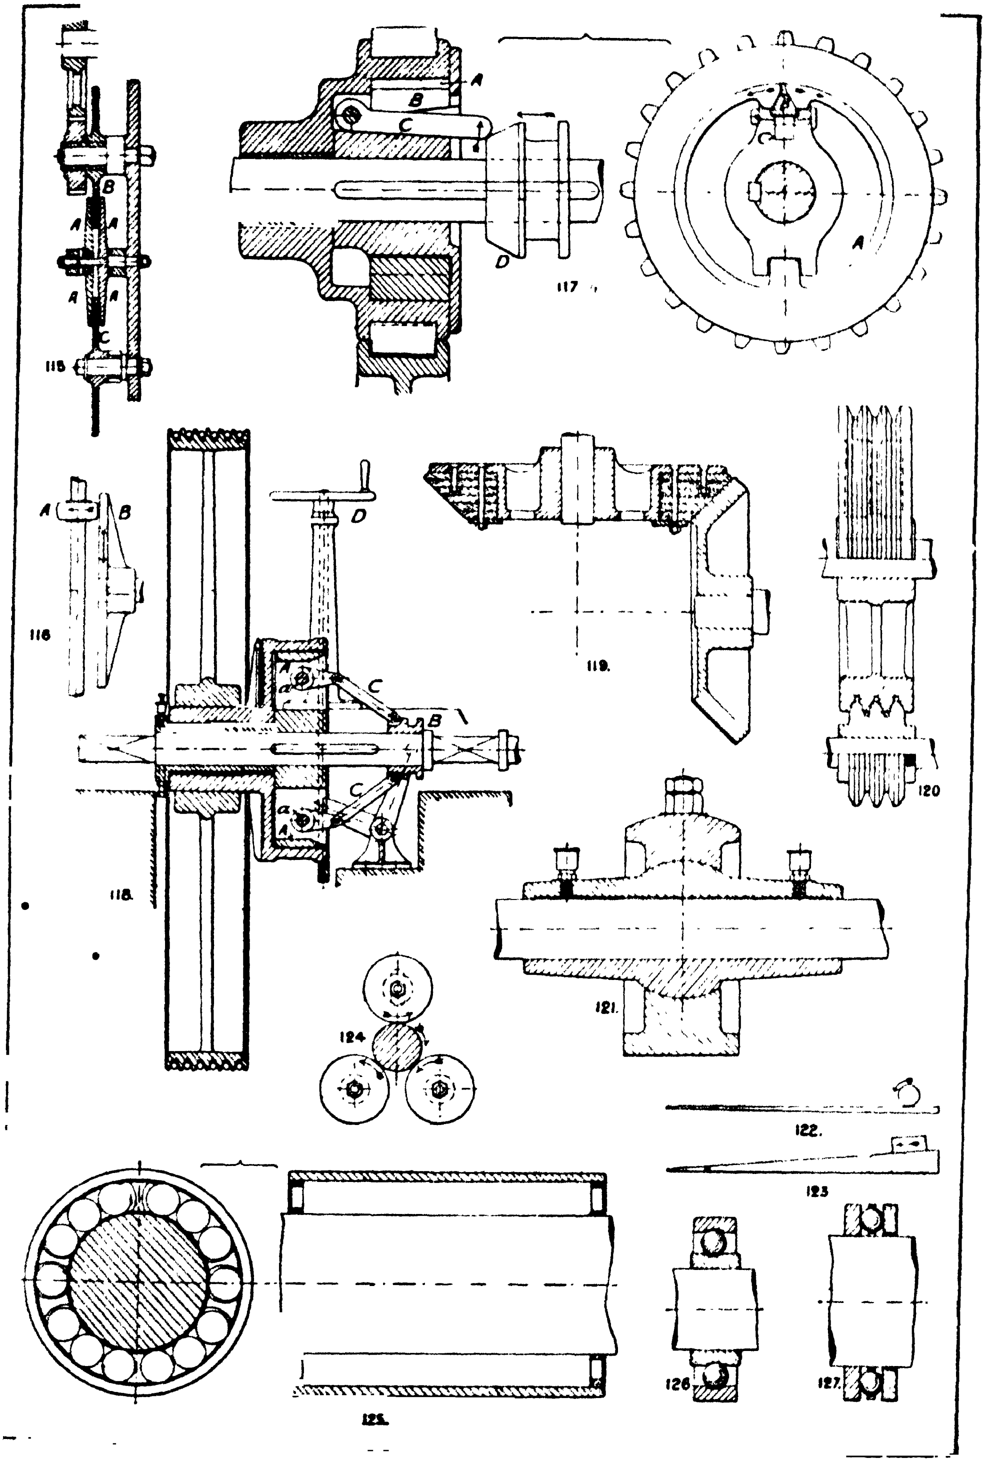
Friction Gears. A fair amount of gearing is made without teeth or cogs. Fig. 119 shows bevel wheels with smooth faces, and spur wheels are made similarly. They drive and are driven by frictional contact alone.

In another way friction is often utilised for the transmission of power, in the wedge gearing [120]. Wheels transmit power by interlocking truncated wedge sections instead of by spur teeth. The advantage is that of very smooth running. In other words the friction is all used for driving, and none is wasted, as in toothed gears. Instant connection and disconnection can be made. Unfortunately, this method of driving is not powerful enough for heavy loads, and its use is, therefore, restricted to light hoists.

Shafting Bearings. In the early part of this chapter the law was stated that friction was independent of the extent of surfaces in contact. Now, that fact is constantly receiving application in the bearings of shafting. Formerly shaft bearings were short, from one and a quarter to one and a half times their diameter, and much trouble arose in consequence, due to their rapid wear and seizing. Now their length is made from twice to three times the diameter or more [121], with resulting lessening of friction per unit area, and greatly enhanced durability. Moreover, the higher the speeds at which machinery is run, the greater is the advantage of increased bearing length for the shafting. This is seen, among other examples, in the shaft bearings of blowers and fans, of circular saws, of moulding cutters, and of grinding machines, where it is common to find bearings from three to four times longer than their diameters.

Lessening of weight on bearings, with the object of reducing the intensity of friction, is studied. Thus, shafting of steel is substituted for that of iron, because steel may be of smaller diameter and of equal strength and stiffness with iron. Pulleys are made of steel instead of cast iron with the same object.

Belting. The friction of driving belts is the important factor in their application. Belts slip if the resistance of their work overcomes their friction. To increase friction as much as possible is the reason why horizontal are preferred to vertical drives, why a long drive is better than a short one, and why pulleys are selected, when possible, not greatly dissimilar in size. It is a question of amount of arc of contact. A horizontal drive is better than a



EXAMPLES OF FRICTIONAL AND ANTI-FRICTION DEVICES vertical one, because the belt sags, and so lies better round its pulley on the driving side. In a vertical drive there is no sag. A long drive is better than a short one, because the sag is greater. Using pulleys reasonably alike in regard to size, the belt makes contact round, approximately, half the circumference, or 180° of arc, but with very large and very small pulleys it makes much less than 180° of arc round the small one, and the belt inevitably slips, an evil which is increased when the pulleys are nearer together, or with a vertical drive.

Out of this great fact of friction comes the important problem of the efficiency of machinery. We have mentioned that in some cases half, or more than half, the power put into mechanism is lost in friction. If a machine sustains such loss, its efficiency is only 50 per cent., and, technically, that is its modulus. This is generally ascertained by means of a brake dynamometer, in which the absorption is measured directly.

Rope Friction. The value of friction is seen in the coiling of a rope round a bar for the purpose of paying out or drawing in, applied in many laborious tasks The labourer employs it in lowering heavy wine and beer casks into underground cellars, the woodman in felling trees. A crowbar is driven firmly into the ground at a considerable angle to prevent the rope from slipping off in the vertical direction. If a cask is being lowered, the rope is payed out in easy stages, and directly the weight begins to overhaul, the rope is pulled round to make a larger amount of contact with the bar, and so the cask descends safely in a succession of stages.

In the work of tree-felling there comes a critical period when the tree approaches a state of unstable equilibrium. That happens when the wood has been chopped away on the side in the direction in which it is intended that the tree shall fall, and sawn nearly through on the side opposite. Then several men pull on the rope attached to the upper part of the tree at one end, and passed round a single sheave pulley at the other, firmly attached to a bar driven into the ground, and another man tightens the free end of the rope by coiling it once or twice round a bar, also driven into the ground. The tree bends, but is still so rigid that it would overcome the strength of the men unless the rope were made fast. The woodman plies the axe again and the men pull, another coil is made, and so on until the tree is bent over sufficiently to bring its trunk well outside its centre of gravity, when its weight ruptures the remaining fibres, and it falls with a crash.

In another way rope friction is utilised, in the warping-cones on wharves and dock sides and on shipboard. The coil of a rope twice or thrice round the body of a capstan is sufficient to bring the biggest vessels to rest, or to regulate their casting off from their moorings into the stream.

Rolling Friction. We now look briefly at the other aspect of friction, that in which the endeavour is made to get rid of it as an undesirable thing. With regard to the two kinds of friction, that of sliding, which has been discussed, and rolling, the distinction is a most vital one. Imagine for a moment what would happen if a brake strap and its wheels were thoroughly greased or oiled with such a sensible thickness of lubricant that the brake and wheel could not come into actual contact. Each particle of grease or oil would be a tiny globule rolling between the surface and preventing contact. Substitute for oil an infinite number of minute steel balls—the effect would be the same, to prevent the surfaces from gripping at all. That would be rolling friction, substituted for the sliding friction of the band and wheel. Hence, if two surfaces can be separated by a rolling object, the friction which absorbs power is nearly eliminated. The ball and roller bearings, now so common, embody rolling friction, and are, therefore, to a great extent, frictionless. Just in proportion as point or line contact in these is substituted for surface contact in the other class of mechanism is the frictionless ideal realised. Here difficulties of manufacturing come in, and also the difficulty of permanence, because in proportion as wear develops does the ideal become defeated. These things will be found treated under MACHINE DESIGN, but it is necessary to draw attention to them here.

The difference between rolling and sliding friction is illustrated in **122** and **123**. A ball or roller will run down a slope of 1 in 200 [**122**], but a block of polished metal [**123**], will require an angle of 1 in 14 at least to slide down.

Fig. **124** shows a common device in which the axle of a treadle lathe runs between three anti-friction rollers with great ease of movement. Fig. **125** is a roller bearing, and **126**, **127** ball bearings of two types, **126** being for a revolving shaft, the equivalent of a journal, and **127** being one to take up end thrust.

PRIZES WAITING FOR INVENTORS

Problems for Men of Imagination. The Defect of the Sewing Machine. Plagues to Conquer. Rewards for Engineers, Architects, Chemists, and Electricians

By ERNEST A. BRYANT

THE records of the Patent Office of this country, like those of America, show that talent often goes unrewarded in our own day, as it did in times which are gone. Between abstract science and invention there is this difference: that in the former, one man's discovery may at once be turned to the advantage of the whole community; in invention, a sound idea may lie dormant for years. Its originator, perchance, has patented it, but has not the means himself to develop it, and cannot find the man with capital necessary to finance him. This unfortunate condition has a two-edged effect: it prevents the original inventor from reaping his harvest, and it acts as a barrier in the way of another man who has a somewhat similar scheme, with which he would be able successfully to proceed had not the hopeless man, who has anticipated him at the Patent Office, first registered some of the ideas vital to the whole project.

Handicapping Industry. How serious may be the effects of a position such as this was shown by the experience of Lord Armstrong, the founder of the great Elswick works. He, with Brunel, prepared to give effect to a plan for the coiling of wire about the inner barrel of his heavy guns. It was one of his earliest ideas, but one which he had permitted to remain in abeyance what time more pressing schemes were carried through. When, however, he came to develop this idea which had lain so long in his brain, he found that the discovery had already been patented. This was a very serious set-back. •The patentees were unable successfully to carry out the idea which they had registered; it was of no use to them, but it stopped the progress of Armstrong along that path. All that he could do was to lay aside his idea for the years which the patent still had to run. Then he was free to give effect to his project, and highly important results were in consequence attained.

The pity is that invention and industry may be hampered in this manner. Many a valuable idea has been permitted to escape by men who could not afford the risk of litigation which its patenting might involve, or who would not face the worry and annoyance incidental to such dispute. The crank, by getting his wild ideas set out at the Patent Office, may bar out the practical man. It is a fortunate circumstance that this vexatious procedure has not a wider application, or we should to-day be restricted to one form of telephone; to one system of wireless telegraphy, and be told—as was a pioneer in electric telegraphy, when the semaphore was the sole method of communication—that there is no further need of development in these directions.

Undirected Genius Runs to Waste Another aspect of the case, which will appeal more to the young man of inventive mind, is the lack of proper direction for genius. Men of undoubted creative ability fritter away their lives on fanciful schemes, believing their poor geese to be all resplendent swans. Those same men, guided aright, might produce work of real value to the community. How many men of skill have wasted hours and money trifling with machinery which they feel certain will solve the problem of perpetual motion! Wonderfully ingenious are some of their contrivances, and often capable of extension in directions quite different from those which their creators contemplated. But, from the machine for perpetual motion, as such, no man is a penny the richer nor one whit the happier. Applied to serious service the talents thus wasted might add to the common stock of useful inventions.

We have already considered a number of ideas to which potential inventors might profitably apply themselves. Obvious needs, like obvious opportunities, are mostly overlooked. The commonplace invention has no attraction for the man of mechanical ingenuity. Yet, as has been shown, some of the simplest devices are those which yield fortunes to their makers, and greatest advantage to those to whom they are sold. Sewing machines were not perfected in the day of Hood, or the "Song of the Shirt" might never have been written. Many years, however, have elapsed since they attained to what we are now bidden to regard as approximate perfection. Yet the poorest, most unimaginative seamstress could point out a glaring defect which apparently has escaped the notice of successive generations of inventors.

What the Sewing Machine Lacks. The great defect of the hand-machine, and, in a lesser degree, of the machine worked by the treadle, is that the spool contains an insufficiency of cotton. Repeatedly the worker has to cease stitching, remove her work, take out the spool and refill it with thread. For the upper part of the stitch, the needle is fed from a reel upon which may be two or three hundreds of yards. What the seamstress needs is a like accommodation from the spool. Either this latter should be larger, or it should be possible to slip in a reel of thread below the place at present occupied by the spool and shuttle, and work directly from that. The sewing machine can at present be made to do practically every stitch possible in hand-sewing; can work elaborate patterns, floral designs, and what not, but so far the question of an adequate supply of cotton for the spool has been beyond the capacity of the inventor. The camera fitted with films gives the idea for this matter of cotton for the sewing machine—and of ribbon for the typewriter. When all the films on a sheet have been exposed, the lot is wound up and taken out, and a new roll substituted. The same scheme should be practicable with a reel of cotton or a spool of inked ribbon.

An Enemy of Mankind. Given a definite objective, men with ability to conquer difficulties will work. Such gigantic problems as the cure of consumption, cancer, and leprosy, engage the minds of many of the greatest men of the age. One by one, fevers and kindred ills are rendered subject to their skill. But there are lesser problems for solution by lesser men. While the present course was in preparation — in 1905 — the savants of Paris sounded a warning against that filthy pest —the common fly.

This insect, it has long been known, carries corruption and disease wherever it goes. To the many counts in the indictment against the fly is added the charge of disseminating cholera, by whose ravages Europe, in 1905, was again alarmed. The horrors perpetrated by the fly cannot be commonly known, or the pest would not be tolerated year after year in every home in the land, in every place where food for human beings is kept. Nor can it be known what a foe to the sick the fly can prove.

It has been demonstrated that the common blowfly will deposit its grubs in the mouth or nostril of a prostrate invalid; that those grubs will eat their way into the brain of their victim, and drive him or her mad. If there were a plague of flies in China or Tibet, we should send out funds for their extinction, but, because they swarm in our midst, we regard them as a matter of course. Perhaps it may be an incentive to ingenious sanitarians if they be reminded that a Paris newspaper—the "Matin"—has offered a prize of £400 to the discoverer of the best method of destroying this dangerous parasite.

Commercial Possibilities of the Rat. Another plague by which we are more or less scourged is the rat. Its depredations represent a vast sum each year to merchants and dock companies, to say nothing of less considered operations in the shops and warehouses of our large towns. Moreover, like the fly, it has been proved to carry disease; it carried bubonic plague to Glasgow. Rats have been known to gnaw the corpses of persons who have died from infectious disease, and then to escape in freedom to spread corruption. Also, they have been found to cause the death of children, biting their flesh as the little ones slept, until they pierced an artery. The rat has apologists only in those who regard him as a useful scavenger. But our sanitary authorities are not so inefficient as to need the assistance of these vermin. Perhaps, if the commercial possibilities of the rat were recognised, there might be greater hope of his numbers being diminished.

The attempt was recently made to popularise the use of moleskin as a fur for ladies. Now, the mole is useful in the extreme to the farmer, who, although compelled occasionally in self-defence to thin out the numbers of his subterranean ally, could not wholly dispense with his services. The skin of the rat has decidedly a market value. Buckland mentions the importation of ratskins from France for glove-making, but adds that his information was that the skins were too delicate except for the finest wear. On the other hand, he mentions slippers made from ratskins which were handsome, durable, and comfortable. The pelt of a grain-fed rat should make as good a covering for feet and hands as many other mysterious materials now sold as kid. There is no waste in the modern manufactory, and the maker of gloves would be hard set for ideas if he could not turn the hide of the rat to good account. Ratskin by another name would be well enough, just as dog-fish sold in the shops of the poorer neighbourhoods has a vogue under another denomination. In some parts of the world, by the way, the rat is a food-staple. It is not popular as diet here. Neither, for that matter, is the snail, although South Down mutton owes its peculiar richness and nutritive qualities to the number of tiny snails eaten by the sheep with the grass in which these small molluscs in myriads make their home.

A King's Prizes. These are not schemes seriously to engage the time of many, though the man who can rid us of such plagues as the disease-spreading flies and rats will deserve well of his fellows. More important to those for whom this section of the Self-Educator is designed are such measures as are contemplated in connection with the Milan Exhibition of 1906. The King of Italy himself offers £1,600 in prizes to exhibitors who comply with the conditions which he lays down.

The first prize consists of £200 for the best automatic safety couplings for railway rolling-stock. This is a phase of work which has long baffled the railway engineer. For many years past railway servants have been agitating for the introduction of such appliances as shall enable them to carry on shunting operations with less risk to life and limb than is now inevitable. Careful as are our great companies, the list of casualties each year among the many engaged in handling freight traffic at the great depots is grievously heavy. The man who can invent the required apparatus will not only realise a fortune; he will be canonised by the men to whom, by his invention, he ensures longer life and relative immunity from accident.

A sum of £200 is offered for the best method of testing high-voltage electric currents without danger to the operator. Investigations in this field may reveal secrets not yet learned by the electrician. The specific want expressed by the King of Italy is sufficiently serious to warrant the investigation necessary. Perhaps the man who discovers the safe and certain way of testing high-voltage currents may also be able to point the way automatically to "deaden" a live wire fallen from its place. With the increase of electric trams in this country, the live wire becomes more and more a peril in everyday life. Our accident list is happily less heavy than that which America has yearly to mourn. It ought not to happen that if a live wire fall, a human being or animal coming in contact with it must almost inevitably be electrocuted.

A Better House to Live in. The two largest prizes offered by the King of Italy are of £400 each—one for the best and most original exhibit of machinery or manufacturing process, a competition of boundless horizon; the other is for the best type of popular dwelling adapted to the climate of Northern Italy. This latter appeals, of course, more specially to the Italian architect. It is suggestive, none the less, of an interest in the affairs of the people which might with advantage be copied in other parts of Europe. The housing problem must be faced sooner or later in this country; perhaps the example of the King of Italy may inspire our Local Government Board to similar enterprise.

It is paying British architects too poor a compliment to imagine that the wretched hovels of our present-day mean streets are the best that they can furnish. Of equal domestic interest is the £200 prize competition for the best established method of distributing healthy and pure milk in centres of population. In England it would seem as if punishment of detected offence—not prevention—is to be solely relied upon. What the individual consumer wants is a cheap instrument which will tell him the composition of the milk sold to him as pure. If the poor housewife were able to detect the presence of added water and boracic acid in the milk for which she pays her hard-earned pence, there would be less deleterious fluid given to add to the inherent weakness of infants.

Navigation of the Future. Motor-boats are the subject of a £200 prize. In this direction England has given the lead to the rest of Europe. But the industry is as yet in its earliest infancy. A turbine steamer made the passage from Dover to Calais in 1905 in fifty-one minutes; when the manufacture of motor-boats is taken seriously in hand by the shipbuilder we may get stout, dependable boats which will carry us across in half an hour. For inland navigation, as well as for sea-going, there is a great future for mechanically driven craft. If our canals are to be developed as they should be, the old horsed barge will have to give way to faster carriers. It would not even now be impossible to build the kind of craft capable of carrying the requisite load at the speed desired. An important consideration, however, is the "wash" caused by such craft. There may be more of fancy than reality in the objections raised. Scotland, when she saw her first steamer, was afraid that all the banks of her inland waterways would be damaged beyond repair by the new-comer. Still Scotland stands where she did.

Telephones at a Penny a Week. One point of interest to inventors is omitted from the Milan Exhibition's prospectus of prizes. The king's list does not include telegraphy or telephony. British inventors, remembering that Mr. Graham Bell, one of the earliest pioneers in telephony, is their countryman, have still to hasten with all their energies if they are to maintain a place in the race for patronage in regard to this science. We want instruments which will record messages without the subscribers being present personally to receive them—messages which can be repeated at will. American inventors are working towards the perfecting of such a machine. They promise, too, so to cheapen the whole process that before long companies will be able profitably to operate the telephone at a cost of only five shillings a year to each subscriber. England will, of course, gain from any new inventions in the United States—by paying for them. It is full time, however, that electricians in this country made their names heard again in this vast, profitable, and fascinatingly interesting field. The late Postmaster-General declared that practically the limit has already been reached in long-distance telephoning. The inventor is under obligation to remove that disability.

A New Kind of Paper. Another industry to which the Milan Exhibition may give a stimulus is paper-making. For a certain class of paper, Italy is our only rival. This make has been called forth by special circumstances. Climatic conditions necessitate special measures in regard to the burial of the dead, and they have had to fashion a paper specially for post mortem wrappings. The paper for which British manufacturers are seeking, and seem at last on the way to find, is one of a somewhat similar character. The "life" of good paper in a library book is very long. The same paper placed underground is much shorter. The fermenting substances in the earth destroy it.

Vast quantities of paper are required by Government and by private firms for electric installations underground. It is an excellent non-conductor of electricity so long as it remains dry. When it becomes moist, however, its value as a non-conductor vanishes. What manufacturers are seeking, therefore, is a paper which will resist damp as resolutely as does indiarubber. A secret process is already under trial, but success is not yet announced. The industrial possibilities of such paper are not exhausted by its application to electric cables; shopkeepers need a good cheap paper of this description. The fishmongers would be glad to do away with the basket if they had the chance. They are awaiting the advent of the moisture-proof paper.

EVENING DRESS

Yokes and Kilted Frills. Evening Gowns and Cloaks. Some Hints about Unlined Skirts. Paper Patterns

By AZÉLINE LEWIS

At the present moment transparent insertions and fancy designs of lace, embroidery, and medallions of fine tucking inserted with faggoting, are the leading features of dressmaking, particularly in the dainty and beautiful varieties of the ubiquitous blouse. All these require good work, much care, and deftness not to stretch the material, and in neatening the edges that are cut away beneath the inserted portion.

If the design is curved or intricate, or anything is inserted separately, and the material a thin or flimsy one, tack it in position, sew carefully all round the edges, and cut away the material on the wrong side, following the shape of the insertion, and neaten round the edges.

Fancy Yokes. For these, lace, narrow ribbon, velvet, or crossway folds may be arranged in any design and united by faggoting, or variations of this. If crossway strips be used, these should be from a ¼ to ⅜ in. wide when made up, for which it will be necessary to cut the material ¾ in. or more in width, to allow for good turnings. Join carefully, open and press seams, snip selvedges, and fold down the edges on each side; then put the two turned-in edges to face, and tack closely on the right side—be careful it does not get twisted—then tack in the position required before working.

As to fancy neck-bands and cuffs, the variety of these is infinite; and plain and tucked silk, net, lace, or chiffon, strips of lace, ribbon, or crossway folds, united by faggot stitching, and many other things enter into their composition. Some of the collars are quite straight, others like our drafting, this being a matter of taste. For such a neck-band, the edges and ends need only be hemmed, and the fastenings may be either silk loops and tiny buttons or hooks and loops, both being, of course, quite small. If stiffenings are needed, they should be narrow silk-covered bones of the depth of the collar, one for the back, and one on each side. For a transparent collar, a lining of chiffon is a great improvement.

The cuffs must be made to the shape of the lower part of the sleeve. If required to fit closely, the opening should be only just long enough to allow the hand to slip through, and be neatened by a hem or narrow bind of the material, so as to show as little as possible.

If stiff cuffs, collars, and revers be required, these must be made upon leno, stiff muslin, or canvas, and arranged on this in the same way as the skirt facing, unless the edge be corded. If the inside is likely to show, the cuff must be faced with silk or sarcenet.

Kilted and Box-Pleated Frills. Kilted, or knife-pleated frills, are now generally done by machine, but if they are to be worked by hand, the top edge of the strip should be turned in, each pleat being small, and touching the last one. Tack the pleats down, being careful to keep them quite straight and to the folds, and then press on the wrong side.

For a box-pleat, make a fold to right and left of the required width, this varying, of course, with the material and depth of flounce. For the double variety, two pleats are made, one over the other, to right and left, which shonld be tacked down carefully. If deep, and the material is rather stiff, several rows of tacking may be required to keep them in position; then press on the wrong side.

Ruchings are made in the same way as box-pleatings, and either single, double, or treble, according to the material and purpose for which they are required. The sewing, however, is done in the middle, and not at the top, as in box-pleatings, and no pressing is required. For chiffon, or soft materials, the pleating should be as close and full as possible.

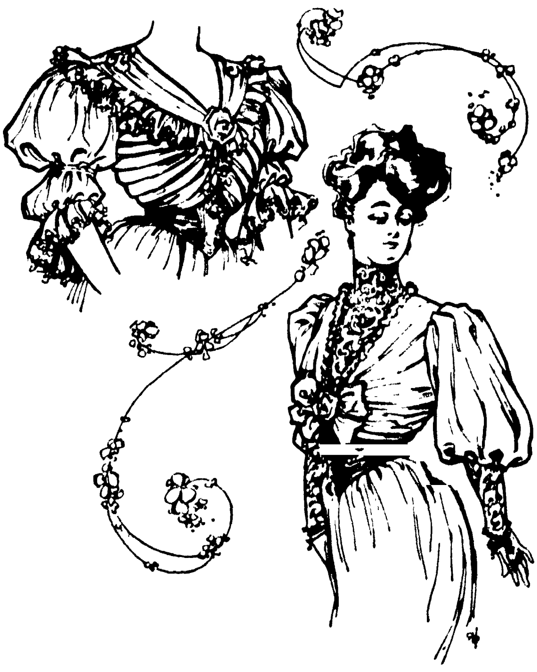
Evening Gowns. Fashion changes so frequently as regards evening gowns, that it is not possible to do more than give the worker a few broad hints. For the styles she will be able to study the various fashion papers. Dresses of a light and delicate nature should never be attempted till the worker is an adept at the machine, and is able to make all kinds of crossway trimmings, pipings, folds, frills, ruchings, flounces, run-on ribbons, insertion, lace; and put on all these things without injuring the fresh look of the material. The delicate fabrics employed for evening and smart summer wear want a light, quick, and sure manipulation to maintain the dainty freshness which should be their first charm. All dresses of a light and delicate texture should be finished as quickly as possible, and very great care should be taken to see they do not get soiled.

A washing overall should be worn, or a long apron and washing sleeves, whilst the hands should be kept scrupulously clean, and as cool as possible. To see that the machine is perfectly clean, try it on a strip of material before touching the garment, so that no unexpected spot of oil or dirt shall get to the needle, and so on to the fabric. Be very careful with the iron and the ironing-board and blanket, and spread a cloth or sheet on the floor when working upon or trying on the skirt. One or two of the latter should form part of a dressmaker's outfit.

Tack strips of muslin to the skirt edge as soon as finished, and also to any other corners and edges as soon as possible after finishing, and anywhere else that is likely to catch and get soiled. If the material, however, be soft and crushable this cannot be done, or, at any rate, it will require much care. But it should be remembered that all frills and ruchings and ornamentations of this kind should not be put on till as near the finish as possible.

A Draped Bodice. The two sketches in diagram 77 give two simple but very becoming arrangements of a draped bodice, the first for day wear, and the second a variation of the same model which effectively transforms it into an evening affair. The day bodice is of fine cloth or cashmere, or any other thin and supple material, with a yoke and under-sleeves of lace; whilst for the dainty evening bodice chiffon, crêpe de Chine or organdie can be selected for its expression, the neck being finished off with a folded fichu, the frill of which is edged with a ruching of chiffon. With the first a pointed rucked belt of silk is worn, and for the second the gathered belt is arranged in a flat-pointed stomacher piece of stitched silk.

For either bodice, the lining is made and fitted separately, according to the directions already given for bodice-making, except that the fronts only are faced with 2 in. of material on each side before the fastenings are put on, these being usually of the edge-to-edge kind.



77. A DRAPED BODICE

The shoulder and under-arm seams are left open till the right front drapery is arranged, which for this style is better pinned on one front, either on the stand or on the wearer, before cutting closely, when the second one can be cut exactly the same. From shoulder and front armhole it should be drawn somewhat tightly, but under the arm to the bust the folds may be a little looser.

The yoke is arranged and sewn on the fronts—and the back also if wished—then the material fronts are gathered under the arms, also a little where the sleeve is inserted, and secured to the corresponding portions of lining. The front edges are gathered and drawn together in the centre of the bust. The right side is caught to the lining, but the left is loose, as the vest fastens under it. The neck-band is transparent and lined with chiffon. It fastens at the back and has the bones arranged as described for fancy collars. The edges of the draped portion are turned in and hemmed, or just caught raw-edged to the material.

The back may be cut a little larger than the lining, and gathered or pleated slightly at the centre of the back, or it may be made the same as the front, but if so, this must be very carefully done to avoid a round-shouldered effect.

If preferred, a plain "stretched back" can be made. This should be cut on the cross, the fold tacked down the centre of the back, taking care not to stretch the material; then smoothed out well towards the shoulders, across the back, neck, shoulders, and under the arms. Be very careful to get this without a wrinkle. Pin and tack in position, then tack shoulders and under-arm seams together and machine-stitch.

For the evening bodice the foundation should be of silk, though fine mercerised sateen looks very well and is much less expensive. This is cut V-shaped at the neck, and is neatened with binding, when the material is arranged and the back and fronts sewn together.

The sleeves in this case may be of silk or chiffon, the latter, if transparent ones be desired. They are cut in the same way as the others, only the puffs are much deeper and fuller, then gathered three times across the lower part to form a second puff, which must be sewn to the chiffon or foundation.

The frills may be accordion-pleated, edged with ruching, which can be bought by the yard, or can be made by the worker, who must allow plenty for fulness. The "chou" bow which finishes off the front consists of a double crossway piece of chiffon, rolled loosely round and round from the centre like a rose, from which depend ends of narrow ribbon velvet, finished off with little rose-buds of the chiffon arranged in the same way.

In such a bodice lightness and quickness are of greater importance than very fine work.

The bodice lining, as may be easily seen, could be cut round or square as desired. A narrow china ribbon should always be run through the neatening at the neck to draw it up, unless a tucker be sewn in, when it is not necessary.

An Evening Cloak. We have selected the evening cloak in diagram 78 because it is one of the latest shapes and is very simple to make, but, at the same time, is capable of being fashioned into a very smart affair, according to the materials and trimmings employed.

In our sketch it is composed of fine, faced cloth, lined with soft quilted silk or satin, the trimming consisting of wide embroidered insertion, or jewelled embroidery, edged with ruchings of chiffon, two handsome ornaments being arranged at each side of the neck.

From diagram 79 it will be seen that it is another variation of the circular shape, and the worker should now be able to draft it with the aid of the measures given, or from the bodice pattern, allowing 4 to 6 inches extra to the chest measurement.

To cut the pattern out of 52-in. cloth without joins, 5¾ yards are required, though there is very little difference in the quantity if pieces be joined on. In faced cloth, each piece must be the right way up of the material.

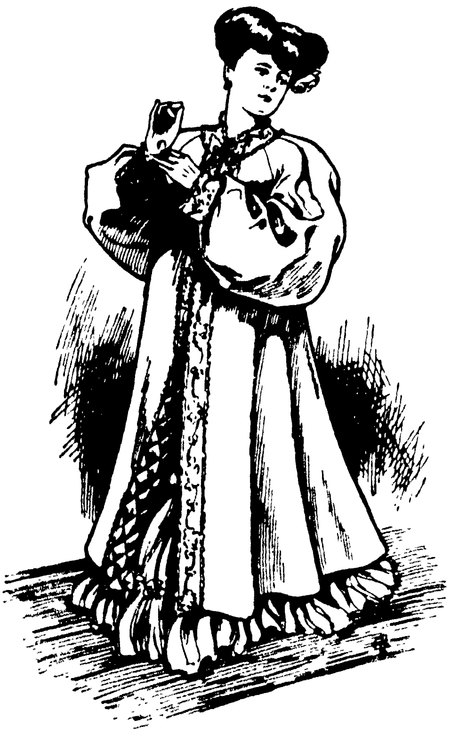
Mark round, and allow ample turnings when cutting out; tack up centre-back, also underarm seams, as shown by the notch; then machine, open and press carefully, first removing the tackings as explained for bodice. Turn in the front edges to the fitting-line over a strip of muslin, also lower edges, and tack down. Tack a piece of muslin to neck and armholes, to prevent these getting stretched whilst tacking the lining in position. This is more easily done *before* the sleeves are put in, as the cloak can be spread out flat. The lining may be bought ready quilted or done by the worker, as preferred. If the latter, join the silk, snip the selvedges, open and press the seams; then open out the wadding, tack the fluffy side to the wrong side of silk, and stitch. If not quilted, the cloak may be interlined with domet.

When the lining is tacked and felled in position at the seams, arrange, tack down, and press the box-pleat in the centre of sleeve; tack and seam up as directed for bodice. Pin and tack sleeve in the armhole, as indicated by the notches at back and front, *easing* it well, and then fit on the cloak to see that the pleat is quite right on the shoulder. If correct, stitch the sleeve in position, cutting away the muslin which was put to prevent its stretching, and press lightly. Pleat, and make the lining exactly the same, tack in position, and then fell the edges to cover seams of shoulder and armhole.

Turn in neck-edge over a crossway strip of muslin, and fell the cloak lining over the turnings; or the edge may be neatened with a piping. Secure hooks and eyes—if wished—to right and left sides, then turn in and fell the quilting to the cloak edges, being careful to pull away the wadding from the edge, to prevent any undue thickness here.

Now make the cuffs, gather and secure the sleeves between the upper edge of these, when the trimming can be sewn on round neck, down the fronts, and round the cuffs. If a stole of silk or material is required, this must be cut from the pattern, as shown by the broken line.

A little pocket on the inner left side, felled to the lining, with a piece of elastic at the top, will be found a great improvement, and can of course be made very pretty, if wished, by being pleated or trimmed with ruching. This, however, as well as the question of the further embellishment of the cloak, must be left to the taste of the worker.



78. AN EVENING CLOAK

Unlined Skirts. Unlined skirts of thin material may be merely hemmed up and not faced, when the edge should be protected with a roll, or "rouleau," of the material sewn just inside the edge of the skirt. This is a much prettier protective finish than braid or binding. An inside frill is also a desirable addition to such a skirt. This frill may be gathered or kilted, sewn on the foundation foot part, or merely to the edge; but with very smart gowns, one, two, or three frills may be employed when there is no question of cost.

Selvedges must be either cut off or snipped, or there will be a puckered effect at the seam. When sewing on plain, narrow velvet, hold it lightly, and just tightly enough to keep the outline, but not to drag or pucker the material. Sew it on with fine silk, making short stitches on the right side and long ones on the inside, so that the stitches will not show.

Folded or swathed belts should invariably be cut on the cross; this should be carefully borne in mind, or the effect of any dress is quite spoilt.

Joins must be carefully attended to, and placed so that they are not seen. If in the sleeves, the join should come in the under part; if in a bodice or blouse, it may be arranged under the arm, but nowhere else unless it can be hidden by trimming. On a skirt, all joins or additions must be at the bottom—at the back part of the gores if to the width, at the foot part if for the length—when the join can be concealed by trimming. It should also be remembered that all pieces added should be cut the same way of the material.

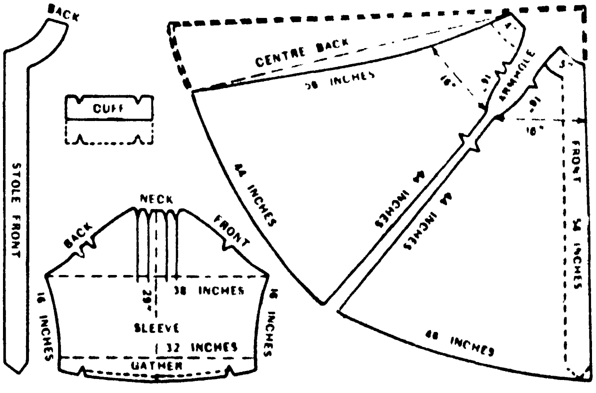
In spite of the advent of the machine, it may be pointed out that handwork still more than holds its own in the higher branches of dressmaking, and even tailoring.

Pressing should generally be done on the wrong side; but if it has to be done on the right, a cloth should be first placed over the material to protect it. Light-coloured fabrics should always be tested beforehand to see if they will stand the heat of the iron; in some cases it will quite change the colour if too warm.

Empire gowns are dealt with in "Underclothing." [See TEA-GOWNS.]

The making of a Princess gown is described in TAILORING.

Paper Patterns. We have gone somewhat fully into the matter of drafting and cutting various patterns, because it is well for the worker to understand this method. At the same time it is quite possible to produce excellent results without this knowledge, and by the aid of good paper patterns.



79. PATTERN OF EVENING CLOAK

But these require management, and any attendant failure should not be laid so much to their charge as to their manipulation and the wearer, whose measurements may deviate somewhat from the correct proportions upon which "stock size" patterns are built.

For instance, a figure whose general measurements may correspond with a 36-in. bust may have a narrower back or a longer arm than the pattern; a tall figure may be shorter, a stout one taller, than the average of their "build."

In taking these measurements, the tape should be placed over the fullest portion of the body.

In measuring for a skirt, for instance, let the starting-point be the hips, 6 in. at least below the waist, because this may be smaller or larger in proportion to the measure, and it is easier to take in and widen the skirt at the waist than to alter the hip part.

The outline should not be interfered with. If only an inch or so too short, lengthen at the bottom, but if several inches be required, insert a piece at the knee-line all round, by which the outline at top and bottom is not interfered with.

In the same way, the skirt may be shortened by making a tuck on each gore at the same place.

For a short, stout woman, pin the pattern round the hips, allowing it to drop in front till this hangs perfectly straight; be careful to get the back right and quite even before fitting the darts and seams from hip-line to waist. Pass the tape round this, pin in place, and mark carefully before cutting off any overplus or uneven parts at the top edge.

With respect to bodice patterns, the same rule as to getting the measure of the fullest portion will nearly always hold good. Some systems vary, however, so it will be well to ascertain the necessary measures before sending for any pattern.

One rule may be given: Get acquainted with each piece of a paper pattern, and study the relation of the various portions to each other before putting together and cutting out the cloth. Also study the notches, and put those together which correspond, as these show where each piece belongs—thus, 1 notch to 1 notch; 2 notches to 2 others, and so on.

The Dressmaker. Though so many have taken up dressmaking of late, there yet seems, unlike so many careers, plenty of room for good workers, who may be pretty sure of always being able to command a market.

But the work is hard and the hours long—whether the worker set up for herself, or whether she work for another. It must be remembered that in dressmaking—as in most things—though theory counts for much, practice alone will make perfect, and no one should think of starting for herself without the knowledge thus gained.

If the worker is desirous of perfecting herself in the higher branches of dressmaking, it may be well to enter some good firm as an improver or assistant. Apprentices in the best houses may have to pay a premium of £60 to £100 in the house, but if living or boarding out, £30 is the average fee.

In dressmaking, specialising prevails more or less in large houses, and good skirt and bodice hands are nearly always in request. Sleeve hands, too, are pretty sure of work.

Fitting is always a separate branch, and as it is the most difficult, is the highest paid in the trade.

Dressmaking concluded

REIGN OF ALEXANDER THE GREAT

Accession and Conquests of a Marvellous Reign. The Great Greek Philosophers: Socrates, Plato, and Aristotle. Closing Days of Greece

By JUSTIN McCARTHY

Alexander's Accession. On Philip's death Alexander came to the throne of Macedonia and its conquered states. Alexander was then in his twenty-first year. His education had been remarkable and exceptional in every sense. When a boy and youth he had had for his preceptor the illustrious philosopher Aristotle. He was under Aristotle's teaching for some three years, but his father had little intention of encouraging his son to devote himself to philosophical studies, and was determined that he should begin as soon as possible the work of political and military government. He was but sixteen years old when his father, who was undertaking one of his foreign conquests, appointed him regent of the kingdom, and Alexander was understood to have shown much judgment, foresight, and statesmanlike firmness in his management of affairs. We have already told the brilliant part he played at the Battle of Chæronea. He had no sooner come to the throne than he found himself compelled to carry on his father's warlike movements in Thrace and even outside the realms of Greece. He received suddenly the news that the Macedonian garrison in Thebes had been massacred, and he rapidly retraced his steps from the shores of the Danube, recaptured Thebes, slaughtered numbers of its defenders, and sold a far greater number into slavery. It is stated that Alexander indulged in the exultant declaration that Demosthenes had called him a child, but that under the walls of Athens he would prove himself, even to Demosthenes, to be a man.

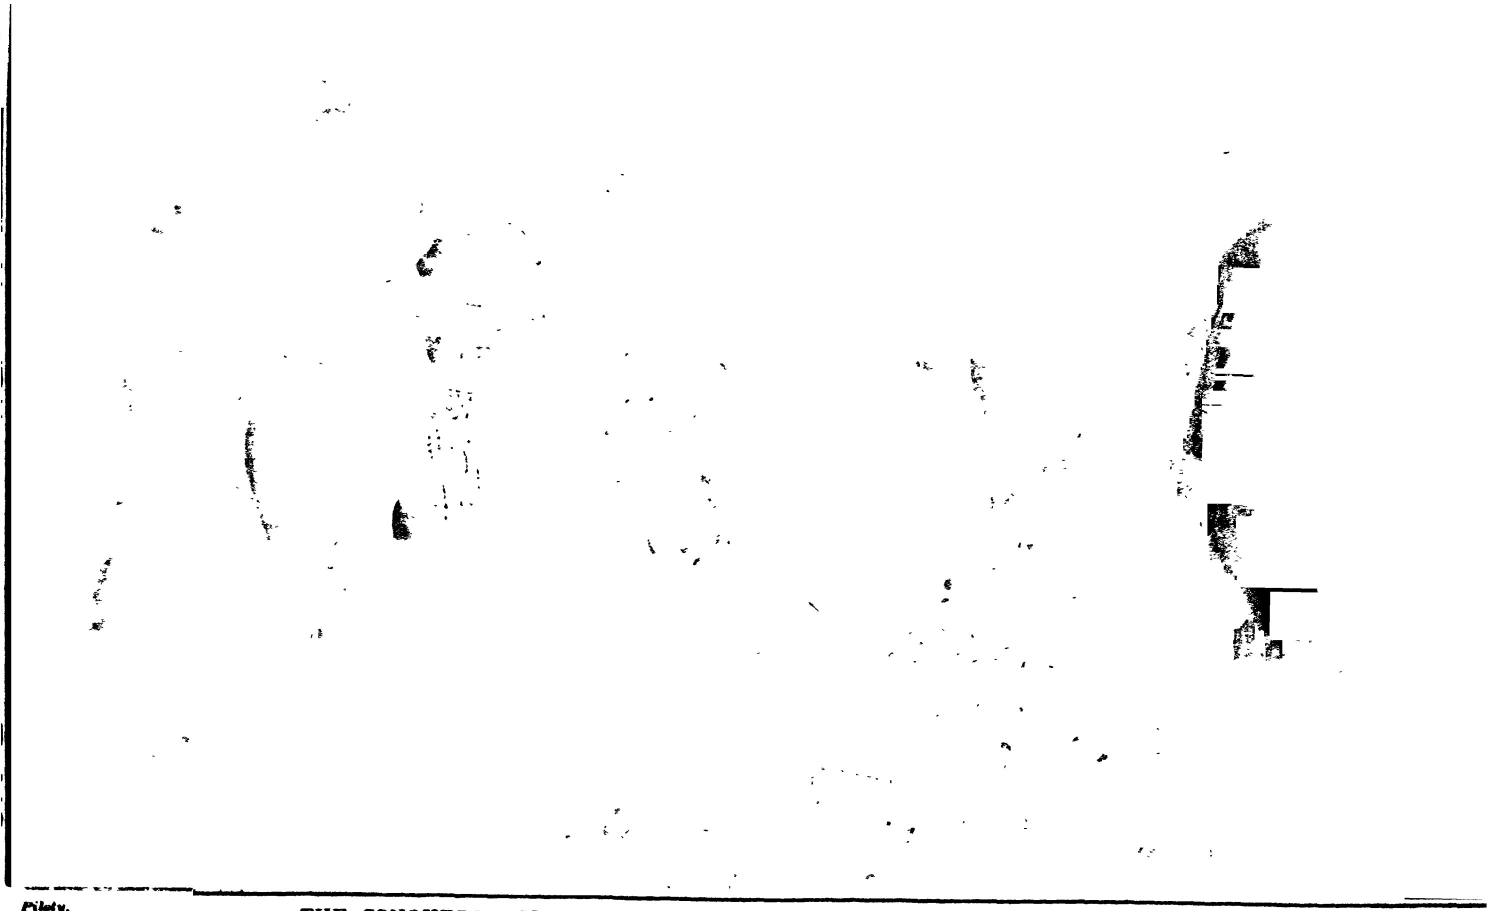
Many Conquests. The Greek states, now brought once again into submission, conferred upon Alexander the title, which his father had formerly held, of Commander-in-Chief for the conduct of the war with Persia. Alexander crossed the Hellespont with an army of 30,000 foot and 5,000 horse, and won a brilliant victory over the Persians near the River Granicus. The Persian army is stated to have numbered more than 100,000 men. The Persian ruler was Darius III., the descendant of the brilliant family, of whom Darius I. was the most famous. Darius III. began his reign in the year that saw Alexander the Great succeed to the throne. Alexander then continued his march along the coast in order to protect Greece from invasion by the foreign allies of Darius, and also to prevent Darius from receiving any assistance towards the repression of uprisings which might occur among his own subjects.

Darius, however, made more than one heroic attempt to check the movements of Alexander, but Alexander defeated him in another battle. Then the conqueror laid siege to the city of Tyre, which he captured after a protracted struggle. He made himself practically master of Egypt, and there founded the city of Alexandria, which he called after his own name. Some historians tell us that in order to conciliate the inhabitants he went so far as to make sacrifice to the accepted divinities of the region, not having any religious principles of his own strong enough to prevent him from performing this singular act of conciliation. He pursued his conquering way through Palestine and Assyria, traversed the Euphrates, where the Persians made no stand, and the Tigris, which they unsuccessfully attempted to defend; and on the famous battlefield of Arbela he won his third and decisive victory over Darius.

An Army of a Million. The army of Darius numbered nearly a million of men, while the Macedonian army had less than fifty thousand. Alexander became thus the possessor of a vast amount of gold and silver taken in the cities of Susa, Persepolis and Babylon, with large stores of jewels, the property of Darius, worth in all some thirty millions of our present money. The value of these spoils is estimated on the authority of Plutarch, one of the greatest of Greek historians, who began his life after the opening of our Christian era, and had thus ample time to collect and study his materials. There seems no reason to suppose the estimate extravagant, for Darius must unquestionably have had vast stores of wealth in that part of his dominions. Darius retreated to his eastern provinces, and Alexander, feeling certain of victory, made no effort to pursue him. The fate of Darius was soon decided. He was killed in his flight by one of his own satraps who had turned against him. Alexander came to Babylon, where he restored the temple which had been destroyed by Xerxes, and he occupied in succession all the other capitals of the late sovereign.

A Stern Conqueror. He was now sovereign of Persia, which he made merely a part of the Macedonian Empire, and he married Roxana, the daughter of a great Persian nobleman. Alexander did not show himself as merciful a conqueror during this part of his career as at its earlier stages. He exercised severe and even cruel reprisals upon some of those whom he believed to be conspiring against him. He was not yet satisfied with his conquests, and was filled with a strong desire to make India part of his Empire.

It happened that one of the sovereigns of a state in India was at that time engaged



Piloty.

THE CONQUEROR CONQUERED: THE DEATH OF ALEXANDER THE GREAT in a feud with another Indian monarch, who besought the aid of Alexander against his rival, and the Macedonian conqueror probably thought this a good opportunity for his Indian enterprise. Alexander won a complete victory over this Indian King, Porus; and to cross the Indus and thus come upon Porus, he caused a whole forest to be cut down in order that he might construct a fleet for the passing of the river. He dealt so generously with his captive, partly no doubt with the view of obtaining the genuine submission and alliance of Porus, that he allowed him to retain his states on condition that Porus should undertake the duty of keeping all that part of the country in obedience to Alexander's rule. The fleet Alexander had created had meanwhile coasted all along the shores, returning by the Persian Gulf, with the object of satisfying the trading world under Alexander's rule as to the facilities for opening up and carrying on an extensive commerce with India. Alexander, meanwhile, built ports, dockyards, and even cities in the territories he had subjugated, and when he returned to Babylon he led his army through deserts which had never before seen the march of a military force.

Statesman and Soldier. Alexander was a great statesman as well as a great soldier. He belonged to that supreme order of military conquerors who prove themselves to be the founders of imperial systems. He understood to the full that, no matter what military force he could obtain from Greece, it would not be within his power to maintain his rule over the Indian territories by any other means than that of liberal and equal laws. Throughout his rule he showed respect for the national customs of the peoples he had conquered, allowed them to maintain their own religious worship, even on certain occasions offering formal homage to their gods. He promoted as far as possible the marrying of Macedonians with Asiatic women, and he did his best to promote a continuous commerce between Greece and the East.

Alexander was still a young man, only thirty-two years of age, and might well have seemed to be still approaching to yet greater conquests. His purpose evidently was to bring Greece into close commercial, political, and military alliance with Persia and the other Asiatic states which he had conquered, and thus to create one vast Macedonian Empire, spreading over much of the West and of the East.

The Death of Alexander the Great. While at Babylon he was suddenly stricken by a disease which came upon him after a luxurious banquet. His illness was probably malarial fever. But Alexander took little account of it, continuing to indulge in heavy drinking; and on the eleventh day of his illness it became evident to those around him that the great career was coming to a close. The portents of the tragedy soon spread; the soldiers crowded into the Royal palace, and many of them were allowed to pass in file beside the bed of their Commander. Alexander was then unable to speak, and could only wave his hand in friendly acknowledgment of their presence. He had before this become certain that his end was near, and had given his ring as a memorial to Perdiccas, one of his lieutenants and friends. When some of those near him asked him to whom he desired to leave his crown, he murmured that he desired to leave it to the most worthy, and that his only fear was lest bloodshed should follow his funeral rites. Then came the end.

A Great Policy. Alexander's reign of conquest had lasted little more than twelve years. He was one of the greatest conquerors the world has known. We can clearly discern, from what is told us by the historians who came nearest to his time, that he had far higher and more statesmanlike projects than those of mere conquest and subjugation by military and despotic power. His policy was to treat the conquered countries with such equity and generosity as might make them his willing and loyal subjects; to endow them with systems of government under which they should be more free and prosperous than they had ever been before; to give them political and social equality, and to make it a personal and patriotic interest with them to become free citizens of his Empire. He had many faults, some of them great faults. He had a vehement and sometimes ungovernable temper, and although in his better moods he was conscious of this defect and strove to control it, there were times when it passed beyond his control and drove him to deeds unworthy of such a man.

Murder of Clitus. One of these deeds was the slaying with his own hand of his friend Clitus, who had saved his life at the Granicus. Alexander and Clitus and their brother officers were banqueting together, and many of the officers paid compliments to Alexander in language which seemed to the plain and sincere nature of Clitus to be that of the most fulsome flattery, such as Alexander ought not to hear without reproof. Clitus expressed his opinions strongly, and when Alexander, roused to anger, rebuked his friend for such interference, Clitus reminded him that the sovereign owed his life to the hand of his friend, and further told him that if he would not endure a just remonstrance he ought to associate only with slaves. Thereupon Alexander, who had probably been drinking very heavily, sprang up and stabbed Clitus with a javelin. The wound proved mortal, and it was said that Alexander never, during the remainder of his life, ceased to repent the crime, committed in the fury of the moment, which had cost him the life of his best and most devoted friend. Many other evil deeds, the result of sudden ungovernable passion, are recorded against Alexander, and although he was usually magnanimous as a conqueror, yet he is accused of having been sometimes guilty of actual cruelties towards those whom he had subjugated

Alexander's was undoubtedly one of those uncertain natures which do not improve by continuous prosperity. Disappointment and what seemed to be the frustration of his plans he always bore manfully, and studied how to put things right and carry his enterprise to success in spite of overwhelming obstacles. But when victory had been accomplished Alexander was only too ready to indulge in the exultation of the hour, and allow his worst impulses to exert their full influence over him. We meet often in everyday life with men who can devote themselves to some great task in art or literature, or in commercial enterprise, with persevering spirit and unshadowed front until that work be fully accomplished; and will then give themselves up to an interval of sensuous enjoyment, and allow the worst impulses of their nature to have unchecked expression, as if such a time were a well-earned holiday after the strain of their toil.

A Complex Nature. Alexander appears to have been such a man. There were in his nature two different men—one whom nothing could turn from his enterprise until it had been accomplished, and one the voluptuary who was then allowed to assert his own prerogatives for the time. But it must remain to his eternal honour that wherever he went as a conqueror he endeavoured to spread the language, the literature, the art, and the civilisation of Greece. Even his occasional toleration and patronage of idolatrous practices and of polygamous habits, which gave occasion to much condemnation by historians, may be set down to his strong desire to gain the confidence of each newly conquered people, to induce them to regard him as sympathetic and friendly, and thus win them to become his peaceful and loyal subjects.

The body of Alexander was buried in a golden coffin at Alexandria. The extent of his conquests, if studied on a map, must seem wonderful when we remember the undeveloped condition of travel in those far-off days, and the almost superhuman difficulties which a conqueror must have had to encounter in transporting his armies through vast regions of unexplored forest and swamp, and in using his rudely made timber fleets for the conveyance of large numbers of men across the seas. The weapons of a civilised army in Alexander's time had but little superiority over the weapons of the uncivilised tribes who strove to oppose his progress, and in the genius of the conqueror himself must have been found the sole key to success. The events that followed the death of Alexander bear the strongest evidence of the right he had to that title which has been universally given to him—Alexander the Great.

An Illustrious Era. The era to which belong the reigns of Philip and Alexander is one of the most illustrious in the history of the ancient world. It was not only—it was not even mainly—an era of conquests; it was an era of letters, of art, of oratory and philosophy. Soon after the death of Alexander the genius of conquest began to pass away from Greece. Alexander's death led to a quarrel as to the succession. His wife Roxana gave birth to a son three months after Alexander's death, and this son, in the ordinary course of things, would have succeeded to the throne, but Alexander had also a half-brother named Aridæus, who claimed the succession. The mother of Alexander was still living and took an active part in the dispute. There was, in fact, a family controversy over the succession, and in the end it was agreed upon, as the only possible compromise, that Alexander's son and Alexander's half-brother should both be proclaimed sovereigns. This division of a nominal authority between an infant and an incapable youth only led to incessant family disputes, which soon broadened into public divisions and international disorders. The Macedonian Empire broke asunder, state after state striving to restore its long-lost national independence. For many years this struggle went on, and Macedonia had to resist invasion from all sides. Meanwhile a new power was arising in Europe which was to make itself felt all over the world—the power of Rome. Macedonia became in the course of time a province of Rome, and the Macedonian Empire was heard of no more.

The Teacher of the World. This is a suitable time at which to make a retrospective survey of the great works which were accomplished in art and literature, in philosophy and in statesmanship, during the days of that Macedonian Empire. The name of Socrates may well hold the foremost place among those who thus made Greece the teacher of the world. Socrates was the son of a sculptor, and was brought up in Athens, where he received the education usually given to young Athenians, but learned in addition, what was not then common, a considerable knowledge of geometry and astronomy, in which he took a deep interest. He served as a soldier in three campaigns, and displayed much courage, energy, and patient endurance; and it is said that he amazed his more experienced war comrades by his absolute indifference to the bitter cold of a winter campaign as well as to its danger.

A Bold Philosopher. He followed his father's occupation as a sculptor, and is credited with having accomplished a marble group which was exhibited in the Acropolis. After a while he abandoned all occupation but that of a teacher of philosophy, and this he taught not in schools, as other philosophers of his time had done, but in the public Forum, in streets and market places, in his own home, and in the homes of his friends. He preached a more enlightened form of religion than that authoritatively accepted in his day; he condemned intolerance of other men's faiths, and he inculcated doctrines of righteousness and purity, and the need of a constant pursuit of knowledge. Socrates would really appear to have believed himself inspired by some higher power as an expounder of philosophy, morality, and religion, and he spoke out his sentiments with a boldness which soon made him dreaded and detested by the rulers of the state. Finally, he was made the victim of a legal impeachment on the ground that he was guilty of blaspheming the recognised divinities of Greece, of endeavouring to introduce to the people new and false gods, and of striving to corrupt the morals of the Athenian youths. He delivered a speech in his own defence, and the courage and eloquence with which he defended his cause probably aroused the pitiless hostility of the tribunal before which he had to plead. Although the vote of condemnation against him was only carried by a small majority, the court condemned him to die by drinking a cup of hemlock. When the appointed time came he quietly drank the hemlock, and died with all the composure of a philosopher and a martyr. He thus passed out of life in his seventieth year nearly 400 years before the Christian era.

Another Great Philosopher. Plato was one of the greatest among the Greek philosophers. There is some doubt about the place of his birth. The general belief is that he was born in Athens, but it is also contended that his birthplace was in the neighbouring island, Ægina. The dispute is not of much importance, for Plato must in either case be regarded as an Athenian. He was born of aristocratic family, and appears in his youth to have begun by writing poems; but he soon applied himself to the study of philosophy, and when he was nearly twenty years old he became the friend and companion of Socrates. That friendship lasted for some eight years, and the companionship was then brought to an end by the death of Socrates. After the death of Socrates, Plato left Athens and visited Sicily, parts of Italy, and even Egypt, striving wherever he went to add to his store of knowledge. Knowledge was indeed the one object of his ambition. He showed no inclination for practical politics, he loved learning not merely for its own sake, but because he believed that through learning alone could man know how to live a truly noble and virtuous life.

The Teachings of Plato. Plato began his career as a teacher. He taught in the Academy, a public exercise-ground planted with noble trees, and from his teachings there his school of philosophy became known as the Academic. Plato also explained and expatiated on his philosophic doctrines in his own gardens, where he could always gather round him a large number of disciples and friends. Plato's teaching was to a great extent a continued exposition of the doctrines taught by Socrates, but he made a more systematic effort to associate them at once with the practical life of man and with man's higher life in the future. Plato contends that man's highest ideal is the recognition of "the good." His interpretation of "the good" corresponds with that given by Christianity. He would not admit that pleasure is man's good, but on the other hand he would not adopt the principles of the Cynic philosophers, that all pleasure is in itself an evil—a doctrine which has to a great extent been accepted by the teachers of many sects from that time to the present. He held that pleasure was good or evil according to its nature, and to those elements in the mental and moral constitution of human beings which it could help to improve or to spoil. Plato lived to a good old age. He died in his eighty-first year, and was seen by his friends for the last time at a wedding feast. He died as he had lived through the greater part of his life—in peace and in an atmosphere of happiness and hope.

Aristotle. Aristotle was the greatest pupil of Plato and one of the greatest philosophers of all time. He was born at Stagira, a Greek colony. In his eighteenth year he settled in Athens, and soon after became a pupil of Plato He founded a school of rhetoric in Athens. The teaching of rhetoric included a certain amount of instruction in law and in politics. When Plato died Aristotle left Athens and stayed for some years in Asia Minor with an old pupil who had now become a man of power. He was afterwards invited to Macedon by Philip that he might educate Philip's son, Alexander, and he continued to be the instructor of Alexander for three or four years. When Alexander started on his expedition into Asia, Aristotle returned to Athens, and there founded a school called the Lyceum, because it was near to the temple of Apollo Lycieus. After the death of Alexander, his friend and protector, his teachings were regarded with disfavour by a powerful party in the Athenian state who were uncompromising opponents of the Macedonian policy and prejudiced against Aristotle, whom they regarded as one of those who favoured it He was accused of impiety—of endeavouring to set his pupils against the ancestral divinities and ancestral faith. Aristotle knew from what had befallen Socrates how easy it was to convict of impiety anyone who endeavoured to inculcate a new religious doctrine. He escaped from Athens and took up his residence at Calchis, in Eubœa, a large island in the Ægean Sea, which had become subject to Athens and is now part of the kingdom of Greece. Aristotle was not given long to enjoy the quiet of his retirement, for not many months after he died at the age of sixty-two.

Other Greek Schools of Philosophy. There were many other philosophers and schools of philosophy in the great days of Greece. There was Zeno, the originator of the Stoic philosophy; there was Diogenes, the Cynic philosopher, who in his maturer days turned so completely against the extravagant living of his youth as to make it his theory that man ought to subdue by hardship and physical pain all his sensuous cravings, and finally, according to the common report, made his habitual home in a tub.

We have already said something about the poetry and the art of Greece, about her orators and historians, and have only to add that the closing days of the independence and power of the Greek states were the greatest days of Grecian genius since the earlier time when the poems of Homer were given to the world, and that Greece, when she passed for ages out of history, passed away at least in a blaze of light.

THE BOOKS OF THE FIRM

Entries of Petty Cash and Stamps. Examining Invoices. Day, Invoice, and Cash Books. Treatment of Sale and Discount Transactions

Continued from page [illegible]

By A. J WINDUS

THE reason why Bevan & Kirk call their principal register of receipts and payments *Bank Cash Book* is to emphasise the fact that all transactions recorded therein pass through the firm's banking account. An inspection of the entries on folio 45 will reveal this more clearly. On September 21st, 1905, two amounts were received of £1 5s. 9d. and £5 4s. 8d., respectively, and these were paid into the bank as one total of £6 10s. 5d. So it is with all the receipts; they are banked on the same day they arrive without any deduction.

Petty Cash. If money is wanted to pay petty expenses, a cheque is drawn and cashed (as on September 20th), and the junior clerk enters in his petty cash book particulars of the cash received and of the manner in which he gradually disposes of it. Trade creditors, except for small sums, are paid by cheque, the creditor's own signature on the back of the cheque (styled an endorsement) being an excellent form of receipt. Could anything be more charmingly simple than this system of dealing with the cash? All the money which comes in is debited to the bank, because the bank *receives* it—every penny of it—and all the cheques drawn, whether for petty cash, trade creditors, or any other purpose, are credited to the bank because the bank *pays* them. [See Bookkeeping Rules *a* and *d*.]

We now understand what effect was produced upon Bevan & Kirk's banking account by the withdrawal of £90 in September last for petty cash. The bank paid the various demands made upon it, and was therefore credited, petty cash being debited with the corresponding amounts. £60 of the total is involved in the amount of £355 14s. 7d. brought forward in the bank cash book. Our copy of this book does not go back far enough to enable us to tell how the £60 was made up, but we do know that, since September 19th, an additional £30 has been drawn for petty cash—namely, £5 on September 20th, £15 on September 23rd, and £10 on September 30th; that is to say, £90 in all. We might now, of course, post the bank account to its niche in the general ledger, but the time for that is not yet.

Stamps. Although we are naturally anxious to perceive the true bearing of a series of transactions (such as we have in the banking account of Bevan & Kirk), and to give it due expression in terms of debit and credit, and finally to distribute the debits and credits among the ledger accounts concerned, we must not overlook a certain set of transactions which still claims our attention. Nor must we forget that we are dealing at the moment with books of original entry. It will be time enough to look into the ledgers when we have prepared the entries in the former for posting to the latter.

Transaction (*b*) in our list is a humble one. To discuss postage stamps after reviewing a flourishing bank account is like descending to the valley after climbing the mountain peak. Nevertheless, it is perfectly certain that office-boys and junior clerks who put careless and slovenly work into the postage book are throwing away chances of self-discipline and future advancement. This book is as much a book of account as the petty cash book, while, as may be seen from the specimen given on page 194, it contains other information useful for reference.

With regard to the item of 5s. for stamps purchased on September 20th, the usual practice is for the junior clerk to hand the money to the post-boy to be laid out in stamps and duly accounted for. The junior clerk then enters the amount in the payment or credit column of the petty cash book—*q.v.*, because cash goes out; and, at the same time, the post-boy enters 5s. under date of September 20th in the left-hand or "Received" column of his postage book, because, from his point of view, cash comes in. Then, in the payment column, he enters, day by day, postages on letters, etc., until he is in danger of exhausting his stock of stamps, when he goes to the junior clerk for more money. In this case the junior clerk unites both offices in his own person, but that makes no difference to the procedure.

The Invoice. Transaction (*c*), Sept. 21. Invoice received from Ord & Mackay for £57 10s.

An invoice cannot be dealt with until the goods to which it relates have arrived.

Before our invoice can be entered it has to submit to a species of cross-examination. It has already undergone a direct examination by the senders, Messrs. Ord & Mackay, to ensure, as far as possible, that everything was in order at the time of its despatch. The questions put to the invoice are these:

1. Is order number given?
2. Are the goods properly described?
3. Are the quantities and measurements correct?
4. Are the prices right?
5. Are the extensions and casting correct?
6. Has the agreed trade discount been deducted?
7. Are the terms and dating correct?

These questions are not all asked by the same person, but whenever a satisfactory answer is obtained it is acknowledged by the *examiner's* initials.

The court of appeal for both parties is the

original order sent by Bevan & Kirk and accepted by Ord & Mackay. To its provisions both the invoice and the goods themselves must conform. If there is any shortage, damage or error in the goods, Bevan & Kirk may send a *debit note* to Ord & Mackay charging them with the amount of the loss. On the other hand, Bevan & Kirk may ask Ord & Mackay to send them a *credit note*, crediting them with the amount of the loss. The result is the same either way. Bevan & Kirk obtain an abatement from the total of Ord & Mackay's invoice proportional to the damage they have sustained. Assuming, however, that everything is in order, the invoice passes into the keeping of the accountant, who gives it a serial number (808) marked boldly in blue pencil on the face of the invoice. He tests the arithmetical accuracy of the invoice, or the junior clerk may do it for him, and then the next thing is to enter it in the Invoice Book in readiness for posting to the account of Ord & Mackay in the Bought ledger.

INVOICE BOOK

	1905	September, 1905.				
808	Sept. 21	Ord & Mackay		57	10	0
850	30	Do.		46	15	3

The entry made, the invoice is placed with the other September invoices until the monthly statements of account come in; then, if any discrepancies arise between the statements and the ledger accounts, the invoices are referred to and matters put right. After this the invoices are filed away in a bundle or box by themselves. By some accountants they are kept loose until the statements, having been paid, come back receipted. The invoices belonging to the several statements are then attached thereto, and the papers are put in among the vouchers, which seems a good way of dealing with them.

Cash Sale. Transaction (*d*), September 21st. Mr. Allday purchased for cash goods value £1 5s. 9d. This is a class of transaction met with in every business. The simplest way of looking at it is to treat it as a cash sale (C. S.). It is a mere accident that we know the name of the purchaser. We should, of course, want the information if we had sold the goods on credit, but not now. All we need think of is that cash came in (debit Cash), and goods went out (credit Sales). Accordingly we shall find the entry in our cash book so arranged.

Transactions (*e*), (*f*), (*g*). Goods were sold on credit as follows:

			£	s.	d.
(*e*)	Sept. 21.	Harold Springer	2	12	0
(*f*)		J. Bruce	11	4	8
(*g*)		Aird Bros.	44	9	10

These three transactions belong to one class—that of sales. Therein they differ totally from (*c*), which was a purchase. We have already explained that the system adopted by Bevan & Kirk in connection with their credit sales is to enter them at convenience throughout the day in the sales day book, the several invoices being copied therefrom.

The entries will appear in the day book as in the Table given herewith.

Our study of selected transactions will be resumed in due course, and thereby an excellent opportunity will be created for earnest students to grapple with the transactions lettered (*h*) to (*u*). It should be pointed out that for the sake of simplicity a record of transaction (*t*) has been inserted in the invoice book in anticipation.

Relation of the Journals. Those of us who are readers of thrilling romances like "Ivanhoe" or "The Wandering Jew" know well enough that story-tellers often leave the hero or chief character in desperate plight while they invite us to follow for a season the adventures of the minor characters. This practice is styled "gathering up the threads." We have sometimes rebelled at such treatment as being a mere stage device, knowing in our hearts, however, that it was essential to the unity and equipoise of the story as a whole. Something of this sort happens in the study of bookkeeping, which, though not a romance, may lay claim to its heroes—which are the ledgers; its principal characters—which are the books of original entry; its minor characters, the supplementary records. To change the metaphor, all parts of our subject must advance by regular steps. We cannot storm the citadel until we have captured the outworks. Hence, we have proceeded on the assumption that when all the journals are understood, it will be easy to learn how to keep the ledgers.

The Cash Book. By journals we mean the books comprised in the list of "books of original entry" [see page 778]. One of the most important of such journals is the cash book. Many authorities deny that the cash book is a journal, and as soon as we are well grounded in the principles of double-entry we must examine their contention, with a view to deciding which is the more scientific theory.

Discount Transactions. Whether we speak of the cash book as a journal or as a part of the ledger bound up separately is immaterial, so long as its form and functions remain the same.

We are already familiar with the form and ruling of a cash book, a specimen folio having been given in the last chapter, when we were dealing with some typical transactions of the firm of Bevan & Kirk. Continuing our study of these we come to:

> Transaction (*h*), September 22nd. Received from Messrs. Brown & Co., Ltd., cheque, value £10 1s. 9d., in settlement of account £10 6s. 11d., less 2½ per cent.

So many of Bevan & Kirk's customers avail themselves of discount terms that a discount column has been ruled on the left-hand side of the cash book on purpose to accommodate items of discount allowed. Each item is entered in a line with the cash item to which it relates; thus, Messrs. Brown remitted £10 1s. 9d., in payment of an account of £10 6s. 11d.—that is, they deducted 5s. 2d. discount, being 2½ per cent. on the latter amount. Since, to Bevan & Kirk, the cheque is a *receipt*, the value of it is entered on the receipt or debit or left-hand side of the cash book, and in a line therewith on the same side, discount 5s. 2d. is entered in the discount column. All this, of course, is a mere preparation for posting in the ledger itself.

GEOGRAPHY

7

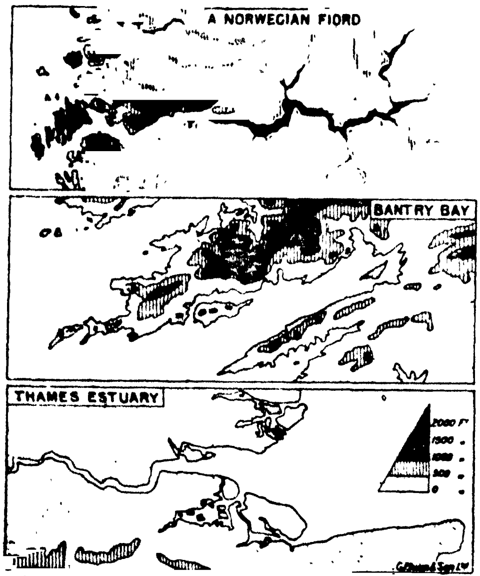
Continued from page 894

OUR OWN COUNTRY

Position, Form, Structure, and Climatic Conditions of our Islands. Vegetable, Animal, and Mineral Productions, with their Distribution

By Dr. A. J. HERBERTSON and F. D. HERBERTSON, B.A.

The British Archipelago. Britain, or the British Isles, consists of the large island of Great Britain—divided into Scotland in the north, England and Wales in the south—and the smaller island of Ireland lying to the west. The least distance between the Scottish and Irish coasts is only about 14 miles, the shortest regular service is 35 miles, and the mail route to Kingstown, near Dublin, rather over 60 miles. Lying off these two main islands are many smaller ones, of which notice the Orkneys and Shetlands, lying north of the extreme north-east of Scotland, the Hebrides and other islands fringing its west coast, the Isle of Man in the middle of the Irish Sea, Anglesey, separated from Wales by the narrow Menai Strait, the Scilly Isles off the extreme south-west of England, and the Isle of Wight off the South Coast, near the middle, separated from the mainland by the narrow straits of the Solent and Spithead. The Channel Islands, near French waters, are politically, though not geographically, part of Britain. Altogether there are over 5,000 islands in the British Archipelago, many of which are mere uninhabited rocks.



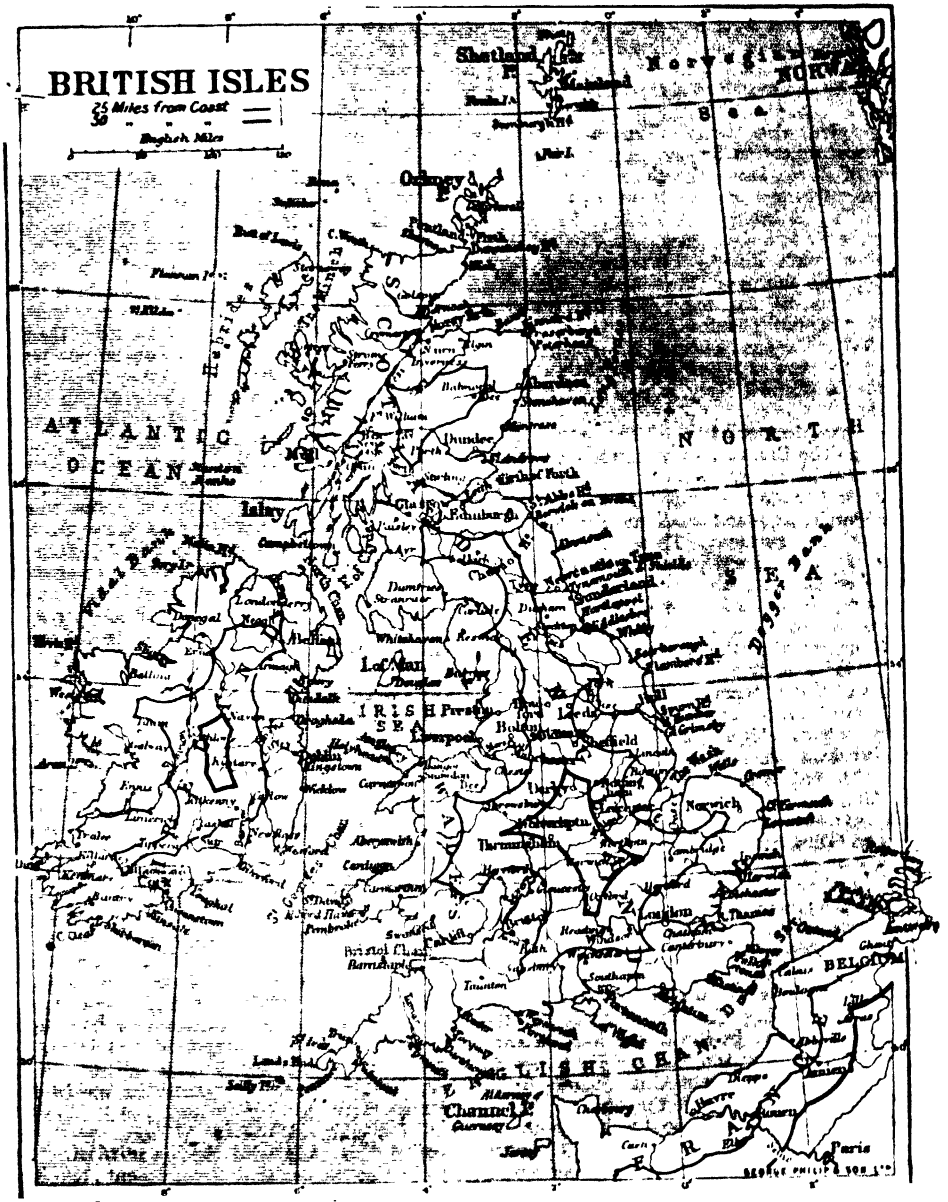
65. BRITISH COASTS AND A NORWEGIAN FIORD: A COMPARISON

The British Seas. West of the British Isles is the Atlantic Ocean, separating them from the New World by nearly 2,000 miles of ocean. Ireland, separated from Great Britain by the shallow Irish Sea, which is entered from the Atlantic by the North Channel in the north and by St. George's Channel in the south, lies like a breakwater off the central portion of the larger island, shielding half of its western coast from the full force of the Atlantic storms. The eastern shores of Great Britain are washed by the shallow North Sea, which opens by the narrow strait of Dover into the English Channel. These shallow seas are unfortunately dangerous to navigation owing to the numerous sunken rocks and sandbanks, of which the Goodwin Sands have perhaps the most infamous reputation. The Dogger Bank, covered by shallow seas, about 80 miles off the Yorkshire coast, is a rich fishing ground, visited by fishing fleets from the surrounding lands.

The British Coasts. The Atlantic coasts differ considerably in character from those of the more confined seas. The former are, as a rule, rugged, mountainous, and deeply cut into fiords and islands. Here the sea has drowned the lower ends of the valleys, partly probably through the gradual sinking of the highland areas. These deep inlets are called loughs in Ireland, and firths or lochs in Scotland. A glance at the map shows how characteristic they are of the Atlantic coasts, not merely of Britain, but also of Norway. The coasts surrounding the confined seas, on the other hand, are, as we should expect, generally low, and often sandy, with high cliffs only where the highlands come down to the sea. The famous white cliffs of the South Coast, dear to the wanderer homeward bound, are the edge of the low chalk heights of southern England. The rivers flowing to the shallow seas from long estuaries are quite different in scenery and mode of formation from the fiords of the Atlantic coast [65], though on a map they look very similar.

The coasts, therefore, both of the Atlantic and of the shallow seas, are deeply penetrated by water, so much so that no place in the British Isles is 100 miles from the nearest sea [66]. The deep estuaries wind far into the land, permitting ocean-going ships to discharge their goods almost in the heart of the country.

There is a remarkable though accidental symmetry in the situation of some of the more important of these openings, which are arranged, as it were, in pairs. In the South of Scotland the head of the Firth of Clyde on the west is only about 25 miles distant from the head of the Firth of Forth on the east. Similar pairs are the Mersey and Humber, about 80 miles apart, and the Severn and Thames, 160 miles apart. Communication between the eastern and western seas by ship canal would consequently not be a very difficult matter.



66. THE BRITISH ISLES AND THE SEA

Showing the accessibility of the interior portions to the sea

Position of Britain in Relation to the Continent. Britain is a fragment of the mainland of Europe, cut off from France, her nearest Continental neighbour, by the submergence of the Calais-Dover isthmus. The shores of France are clearly seen from Dover, which is only 22 miles from Calais. Note also (1) that the estuary of the Itchin, or Southampton Water, is opposite the estuary of the Seine in northern France, from which it is just over 100 miles distant; (2) that the estuaries of the Thames and Stour on the east coast of England are exactly opposite the mouths of the Rhine on the opposite coast of the North Sea, at approximately the same distance; and (3) that the estuary of the Humber further north on the east coast of Britain is opposite the estuary of the Elbe in Germany, though in this case the distance is not far under 400 miles. Britain, therefore, is insulated, but not isolated, as has been wittily said. Her island position protects her against invasion by land, and saves her many costly military burdens. On the other hand, the warder seas are not too broad for her to keep in touch with the march of civilisation and ideas in Europe.

Bridging the Seas. The estuaries which help communication by sea impede it by land. Some of these have therefore been bridged, and others tunnelled. In Scotland the estuary of the Tay is bridged at Dundee by the Tay Bridge, over two miles long. Further south the towering Forth Bridge, 1½ miles long, unites the opposite shores of the Forth. The Menai Bridge connects Anglesey with the mainland. The Severn and Thames are both bridged and tunnelled. Various schemes are suggested for uniting the two sides of the English Channel. Of these a channel ferry is probably the most feasible.

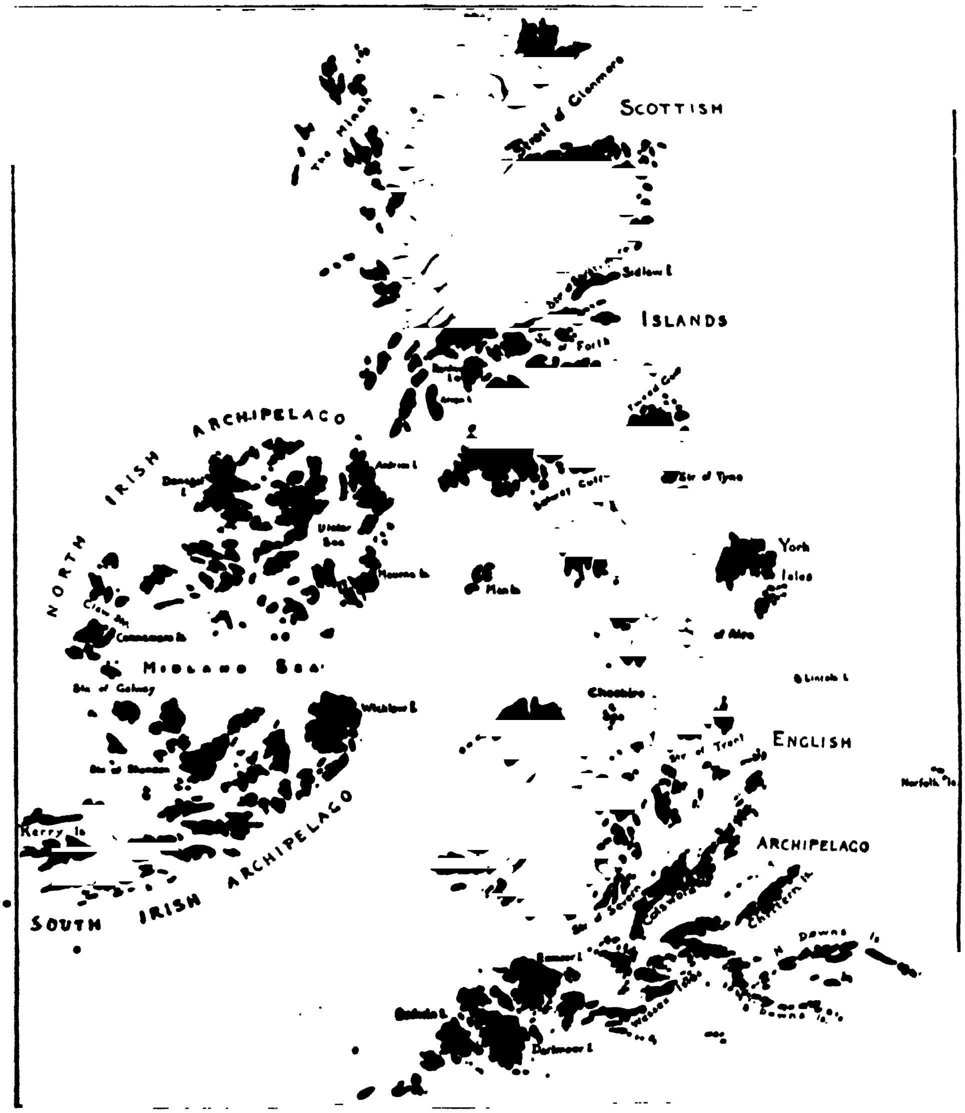
An Imaginary Map of Britain. If the sea round the British Isles were to rise 600 feet, the present islands of Great Britain and Ireland would be transformed into an archipelago of many islands, large and small, most of them very irregular in surface. These islands would represent those parts of Britain at present more than 600 feet above sea-level. The seas separating them would represent the parts at present less than 600 feet below sea-level. Fig. 67 shows what the new map of the British Isles would look like. Beginning in the north we should have, where Scotland used to be, two large islands separated by a long, very narrow strait. These would represent the North-western and Grampian Highlands respectively, and might be called North Island and Grampian Island. The long, narrow strait between—a mere silver streak—would represent Glenmore—the Great Glen—the long, narrow valley at present filled by a chain of lakes connected by the Caledonian Canal [67]. South of Grampian Island a stretch of broader sea, in places nearly 50 miles wide, covering the broad valley which has been riven by movements of the earth's crust between the mountains on either side, would be studded by islands representing the Campsie Fells, the Ochils, and others. In the east a long, narrow island, representing the Sidlaw Hills, would be separated from Grampian Island by a broadish strait representing the present vale of Strathmore. Still further south the mountains of southern Scotland, the Southern Uplands, would form a large, irregular island, separated from islands representing the northern uplands of England, by a narrow strait similar to that of Glenmore, and representing the present Eden and Tyne valleys.

Imaginary Islands. The northernmost of these English islands, North Pennine Island, representing the mountains of Cumberland and Westmorland, and the Northern Pennines, would be cut by deep arms of the sea, representing the Eden and Lune valleys. An extremely narrow strait, corresponding to the valley of the Aire, would separate North from South Pennine Island. Off these, to the east, separated by a broad strait covering the present vale of York, would lie a group of islands representing the Yorkshire Moors and Wolds, while off the south-west would be a large compact island, representing the Cambrian Highlands of Wales, separated from the South Pennine Island by a broad strait covering the present counties of Lancashire and Cheshire. South of the Island of Cambria, and separated from it by seas somewhat broader than the present Bristol Channel, would rise islands representing Exmoor, Dartmoor, Bodmin Moor, and other heights of Devon and Cornwall.

Eastern Heights. The islands in the seas to the east of these islands—east of a line drawn on our present maps from the mouth of the Exe in Devon to the mouth of the Tees in Northumberland—would be small and far apart; while east of a line drawn from the head of the Humber estuary to the head of the Thames estuary solitary islets would represent the hills of Norfolk. Most of the islands of what we may call the English Archipelago would lie in roughly parallel lines, running from south-west to north-east. The most northerly of these chains of islands would represent the heights, often rising steeply from the plain, which separate the basin of the Severn to the west from that of the Thames to the east, the highest being the Mendip Hills of Somerset, and the Cotswolds of Gloucestershire. The next chain, with their chalk cliffs, would represent the chalk heights of Dorset and Wilts, the Chiltern Hills, and the heights of Bedfordshire and Cambridgeshire, while many of the straits between them would correspond with the valleys of the Thames and its tributaries. A crescent-shaped group of small islands still further south, also with chalk cliffs, would represent the present North and South Downs.

In Ireland we should have two archipelagoes of islands of no great size, separated from each other by a Midland Sea at least 60 miles wide, unbroken by islands except in the west. The Northern Archipelago would include the mountains of Ulster and Northern Connaught, the Midland Sea would represent the midland plain, of which a line drawn from Dublin Bay to Galway Bay is approximately the southern boundary, while the islands of the Southern Archipelago would represent the mountains of Munster and South Leinster.

The Actual Map of Britain. Comparing this map with the present relief map of Britain we see that Great Britain, the larger island, consists of two very different portions divided from each other by a diagonal line running from south-west to north-east. North and west of this Exe–Tees line lies a highland region, with few lowlands. South and east of the Exe–Tees line is a lowland region, with few highlands. The highland region consists of older, harder rocks, and is related in structure to the mountains of Scandinavia. The lowland region is formed of younger, softer rocks, which have been worn away over a large part of its area, leaving the three lines of heights already mentioned. This part of Great Britain is akin



67. THE BRITISH ISLES SUBMERGED TO THE HEIGHT OF 600 FEET
The actual coastline forms the 100-fathom depth-line, or edge of the Continental shelf

to the neighbouring mainland, and forms part of the European lowland. Ireland is a plain diversified by heights, and not a highland region divisified by lowlands.

The Lowlands of Scotland. We must now notice more in detail the position of the lowlands, for in these the population of the country is concentrated. Observe how the north-west of Scotland and the adjacent islands are almost entirely highland. There are lowlands in Lewis, the largest island of the Hebrides, in Islay, Arran, and others; but on the west coast of the mainland, as far south as the Firth of Clyde, the mountains come right down to the sea. In the east are the small lowland of Caithness in the far north and a narrow coastal lowland which runs almost unbroken south round the Moray Firth, and widens in Elgin and Banff to the lowland of North Aberdeenshire, with its group of busy towns. The area of these small lowlands is inconsiderable compared with the great compact mass of the highlands. In such a country, therefore, consider the value of the natural rift of Glenmore, which affords a unique means of communication between east and west. Equally clear is the importance of the Tay valley, which connects the Highlands with the

Midland Plain of Scotland, where the population of the country is concentrated. In this plain, which extends, broken by numerous heights, from the estuary of the Clyde to the estuary of the Forth, lie, as we should expect, almost all the important towns of the country.

To the south of it the Southern Uplands widen out again, with coastal lowlands in the east and west. The eastern lowland narrows abruptly where first the Pentlands and then the Lammermuirs approach the sea, making Edinburgh, at the base of the Pentlands, the key of Scotland, and Dunbar, at the base of the Lammermuirs, the key of Edinburgh. The Cheviot Hills connect the Southern Uplands with the Northern Uplands of England. Throughout this region the lowlands are chiefly associated with the river valleys. Notice the importance of these means of communication. The valleys of Annan and Clyde provide a direct route to the north; the Tweed valley—the only populous part of the southern uplands—opens up the country from east to west; and a route to the south is afforded by the valleys of the Teviot, a tributary of the Tweed, and of the Liddel, flowing to Solway Firth.

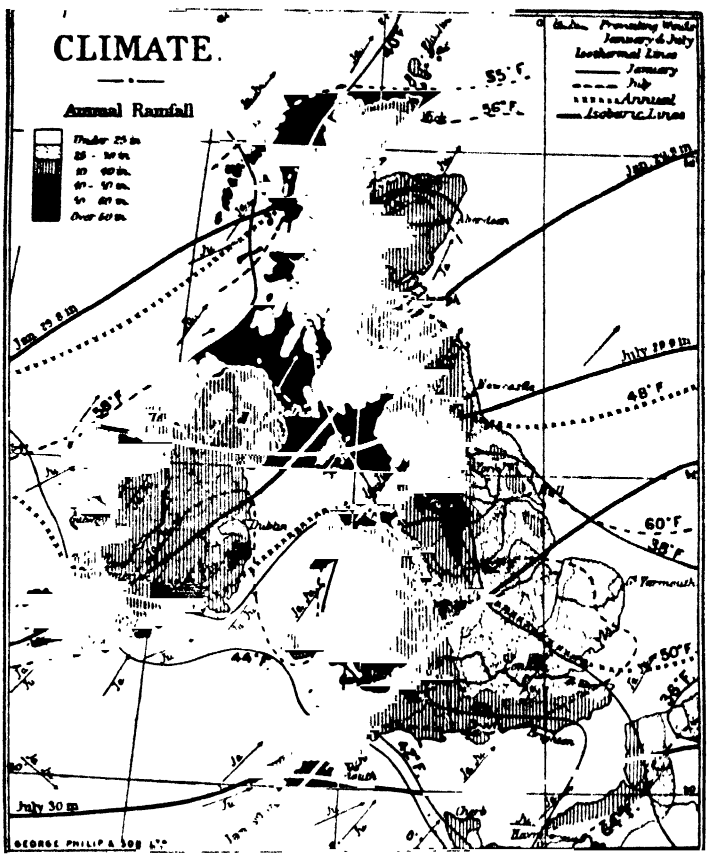
The Lowlands of England and Wales. The Tyne valley—or the Tyne gap, as it is often called—is a route between east and west, between the Cheviots and the Pennines. Notice also the Eden lowland in the west, driven like a wedge between the Pennines and the Cumbrian mountains of Cumberland and Westmorland, and its importance as a route. The lowland of York, east of the Pennines, is drained by the Ouse and its tributaries, one of which, the Aire, divides the Northern from the Southern Pennines. The Aire gap, like the Tyne gap, is all important as a route between the lowlands east and west of the Pennines. West of the Southern Pennines, the Cheshire plain between the Pennines and the Welsh mountains opens from the central plain to the Irish Sea exactly opposite the Midland Plain of Ireland. It is consequently the most direct route between the capital of England and the capital of Ireland. Wales has a coastal lowland continuous with the Cheshire plain, narrow in the north and west, but broadening out in the south along the northern shores of the Bristol Channel. Towns and routes in Wales are chiefly in this coastal lowland and the valleys opening to it. The southern lowland of Wales opens by the Severn valley to the plain of England, the northern part of which is drained by the Trent, flowing to the Humber, and by a number of rivers flowing to the Wash, of which the Great Ouse may be noted. The southern portion of the plain, which is broken by numerous heights, is drained by the Thames and its tributaries, and by smaller rivers flowing to the North Sea and the English Channel.

The Lowlands of Ireland. In Ireland the Midland Plain is the chief lowland, running east and west across the country. The other lowlands run for the most part north and south, following the direction of the rivers. In the north the lowlands of the Foyle and Erne separate the mountains of Donegal and Sligo on the west from the central heights. Further east, between these and the Antrim and Mourne mountains, are the lowlands drained by the Blackwater and the Bann. In the west the Shannon, a river of the plain, cuts its way between the mountains of Tipperary and those of Galway and Clare, much as the Thames has done across the chalk heights of southern England. Look out in the map the lowlands of the Blackwater, east of the Kerry mountains of southern Ireland, the extensive lowlands drained by the Barrow and its tributaries, which separate the central heights of southern Ireland from the Wicklow mountains, and the lowlands south of these, drained by the Slaney.

Climate of the British Isles. Our climate is greatly influenced by the proximity of all parts of our islands to the sea, a circumstance which makes our winters mild and our summers cool. The average, or mean annual temperature of the lowlands of England and Ireland is over 48° F., while in the Lower Thames valley, round the south coast of England, and in the lowlands of Cornwall and Devon, it is over 50° F. The January and July isotherms—*i.e.*, lines connecting places of the same average temperature in summer and winter respectively—remind us in many ways of the corresponding isotherms for the Continent [68]. In January the lines run, on the whole, north and south, independently, that is, of the lines of latitude; in July they run, on the whole, east and west.

Winter Temperature. Taking the British isotherms for January, we notice at once the remarkable differences between east and west. The line for 44° F. cuts the extreme west of Southern Ireland and Cornwall. These parts of our islands are 6° warmer in winter than the coldest parts of the east coast of Great Britain. The line for 42° is, on the whole, parallel, but it takes an upward bend over the St. George's Channel, for the sea is warmer than the land in winter. The rest of Ireland has a temperature of 40°, but in Great Britain the only parts which are equally warm are the extreme west of Scotland, Wales, and that small part of England which lies west of a line drawn from the head of the Bristol Channel to Southampton Water. The rest of Great Britain has a January temperature of under 40°. The coldest parts everywhere when height is left out of account, are all in the east, with a temperature of 38° or under. Notice that the eastern counties, from the Humber to the Thames, are as cold as the counties round the Moray Firth, although they are much further south. The extreme north-west of Scotland is warmer than the extreme south-east of England. This shows that the distribution of winter temperature is largely independent of latitude. The all-important factor is the prevalence of westerly or south-westerly winds, which have been warmed by passing over the surface of the Atlantic Ocean. They reach our western shores as warm winds, but as they pass east over the land they gradually become cooled by contact with its cold surface. Hence the eastern parts of our islands are markedly colder than the west.

Summer Temperature. In summer the case is reversed. The Lower Thames basin, which was one of the coldest regions in January, is the hottest part of Britain in July, with a temperature of 64°. The rest of the English plain, except round the coast, has a temperature of 62°. The line for 60° includes the south-eastern corner of Ireland, the whole of Wales, and most of northern England. The line of 58° almost coincides with the north coast of Ireland, and follows the west coast of Scotland for a considerable distance, curving gradually inland to the east coast near Aberdeen. North of this line the lines for 56° and 55° are nearly parallel to each other. Only the Orkneys and Shetlands have a summer temperature below 55° F. In summer, therefore, the east is hotter than the west, but the south is hotter than the north. The relative coolness of the west is, of course, explained by the influence of the Atlantic winds, but we see that their influence is much less marked than in winter, when they blow more strongly and steadily.



68. CLIMATE OF GREAT BRITAIN: RAINFALL, ISOTHERMS, AND ISOBARS
The darker the tint, the heavier the rainfall

Advantages of the British Climate. Our great climatic advantage is our mild winter. Britain lies far west of the isotherm of 32° F., the freezing point. Even in the coldest parts of our islands protracted frosts seldom occur, and the check to vegetation is not very considerable. Our ports are ice-free all the year round, as are our inland waterways. Our summers, though never oppressively hot, are warm enough—except in the extreme north—to bring wheat and many fruits to perfection.

Distribution of Rain. The proximity of the Atlantic influences our rainfall no less than our summer heat and our winter cold. The winds which blow from that ocean—and they blow on an average for two out of three days—are loaded with moisture when they reach our western shores. As they blow all the year round, we have rain all the year round; but they are strongest and steadiest in winter, which is our wettest season. As we should expect, the west is wetter than the east. Had the highlands of Britain lain to the east instead of to the west, the difference in the rainfall of east and west would have been much less marked than at present. As it is, the highlands lie full in the track of the rainy winds, which part with most of their moisture on the windward slopes. The wettest parts of the British Isles are the Connemara and Kerry mountains in the West of Ireland, which have over 60 in. of rain in a year, the highlands of Scotland, and the mountains of Cumberland, Wales, and Cornwall. The plain of England has a rainfall of under 30 in.

It is interesting to compare the rainfall map of Britain with the temperature map for July. We see that the regions with the hottest summers are, on the whole, the drier parts of the country, while the wettest districts have the coolest summers. The effect of this on agriculture is very important. If the summers in the English plain were wet, neither cereals, hay, nor fruit would come to perfection. The western highlands intercept just enough of the rain to provide almost ideal agricultural conditions in the eastern lowlands. Had the lowlands lain in the west, Great Britain would have been in the main a pastoral country, with a less dense population than at present.

Storms, Cyclones, and Anticyclones. Destructive storms frequently visit our coasts, especially in autumn and winter. The first sign of their approach is generally the fall of the barometer. This shows a diminution of atmospheric pressure when an area of low pressure, or an atmospheric depression, as it is called, is moving towards our islands. These depressions usually come from the west—very rarely, indeed, from the opposite direction. As the depression moves onward, air is drawn in from all sides from regions of the atmosphere which are at a higher pressure, producing violent gales, blowing from all directions spirally inwards to the centre of the low-pressure area, which itself remains calm. If the depression is a large one, these gales may last for several days, gradually decreasing in violence as pressure is equalised. Such a moving system of winds blowing inwards towards a calm centre is called a *cyclone*. In winter, when the temperature conditions on which the distribution of atmospheric pressure partly depends are most unequal over the Northern Hemisphere, cyclone after cyclone may occur for many weeks. When the track of the centre of the cyclone lies north of our islands, the winds over the British Isles blow from the south or west, and the weather, though wet and stormy, is mild. If the storm centre is moving south of our islands, we are swept by icy gales from the north or east.

In an *anticyclone* the conditions are reversed. The winds then blow outwards from a calm centre of high pressure towards regions of lower pressure. When anticyclones occur in winter our weather is fine, but intensely cold, owing to the loss of heat by radiation in the calm, cloudless nights; on the other hand, when they occur in summer, our weather is calm, warm, and hazy.

Vegetation. Britain lies naturally in the temperate forest area. The whole of the lowlands were once covered with dense forests, composed in the south of oak, elm and beech, mixed with conifers in the north. Traces of this vanished mantle of forest remain in such patches as Epping Forest or the Forest of Dean, and in such names as Ettrick Forest or Sherwood Forest. To-day only about 4 per cent. of Britain is woodland, 50 per cent. is in crops or grass, 30 per cent. is grazing land, and the remainder consists of mountains, water, roads, etc. Agricultural land is found chiefly in England and Wales, of which three-quarters and three-fifths respectively are under cultivation. In Scotland and Ireland only about one-quarter is cultivated, and grazing is much more important, employing one half of the total acreage of both. In England less than one-tenth is grazing land, and in Wales only one-quarter. Taking Great Britain only, and examining these figures, we should conclude that the relation between agricultural and grazing land depends chiefly on the distribution of relief, the lowlands being agricultural, and the highlands pastoral. And this is quite true. It is true, however, largely because the highlands are wetter, as we may see by comparing the figures for Scotland and Ireland, which differ greatly in relief. For the same reason, we find a difference even in the lowlands of England, agriculture being more important in the drier east than in the wetter west.

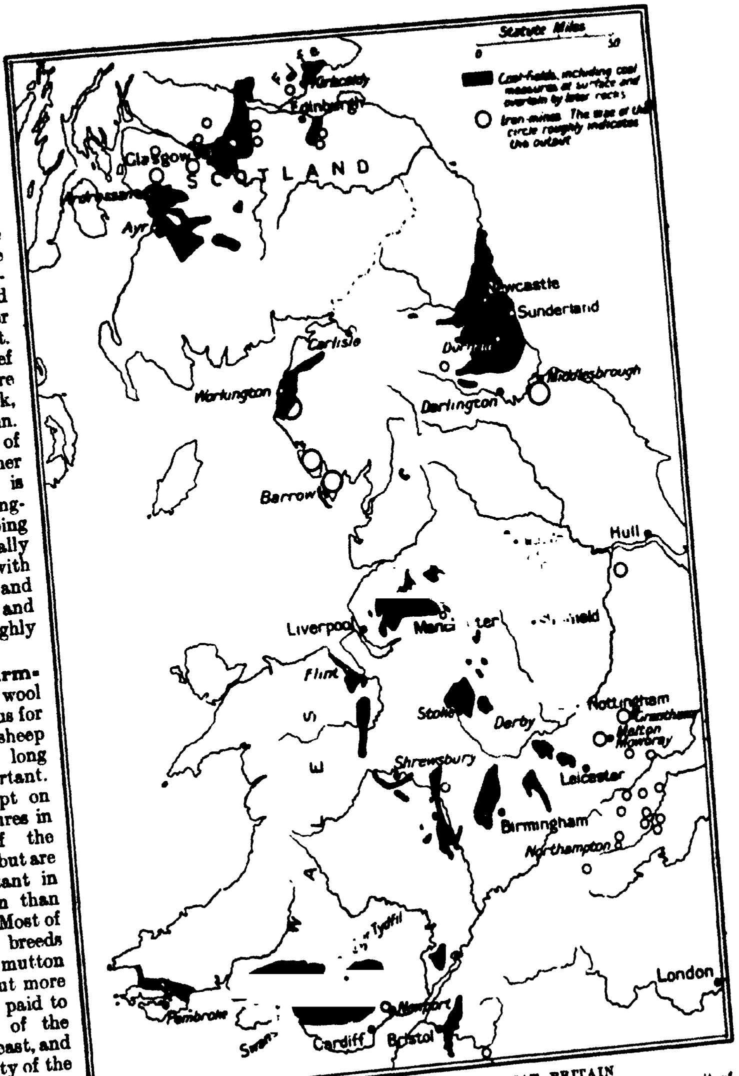
Soils. The distribution of agriculture no doubt depends also on soil, and this again on the character of the underlying rocks. We saw that the highlands of Britain consist of old and very hard rocks, which weather slowly, forming but little soil, most of which rivers carry down to the plains. Where the rocks are softer the soil is much deeper, and of a very mixed character, consisting not merely of the waste of the rocks immediately below, but also of rock-waste of many different kinds brought down by rivers and by the long-vanished glaciers which once covered a great part of our islands. [See GEOLOGY: The "Ice Age."] The local variations are, nevertheless, very great, and every eye detects the difference, for example, between the white soils of the chalk districts of Sussex, or of the limestone districts of Gloucestershire, and the rich red earth of the sandstone districts of South Devon.

Chief Crops. The chief crops are cereals. Wheat and barley are grown in the south-eastern counties, and in the east of the midland plain of Scotland. Oats and barley are grown on the poorer, higher, or more northerly soils. Root crops are cultivated everywhere, but not on the best soils. Potatoes are important in the higher and wetter agricultural districts, and are the staple crop in Ireland. Hops are grown in Worcestershire and the southern counties, those of Kent being specially famous. Fruit is less grown than it should be, especially by the peasantry, who thereby miss a source of profit. Apple orchards and fruit farms are important in the southern counties, particularly in Kent, Devon, and the Severn basin. Flax is grown in the north-east of Ireland, but not so commonly as 30 years ago. Many useful crops, such as the sugar beet, are not grown at all. English agriculture, as a whole, suffers from our land system, the lack of technical education, and the reluctance to adopt the co-operative methods which ensure success in other countries.

The Pasture Lands. These are of two kinds—the moist water meadows of the lowlands of western England and Ireland, which are suitable for the finest breeds of cattle, and the poorer, less succulent pastures of the uplands, or highlands, which are not rich enough for cattle, but suit sheep. Broadly speaking, cattle are fed in the lowlands and sheep on the hills.

Cattle are bred both for beef and for dairy purposes, the latter requiring the richer pasture. The Shorthorn breed is suitable for both purposes. Ayrshire cattle, and the breeds named from Jersey, Guernsey and Alderney are primarily dairy cattle.

In England cattle are most numerous round the western base of the Pennines—in Lancashire, Cheshire, and Staffordshire, in Leicestershire, in the Midlands, in Somerset, Devon (famous for its



69. COAL AND IRON FIELDS OF GREAT BRITAIN

There are workable seams of coal in the carboniferous limestone and millstone grit of Scotland, but these areas are not shown in this map

Devonshire cream), and Cornwall. Pembrokeshire is the chief cattle-raising county in Wales. In Scotland cattle are chiefly bred for beef, and are numerous only in the Midland Plain, large numbers being imported from Ireland to be fattened for the London market. In Ireland the chief grazing counties are Galway, Limerick, Meath, and Dublin. A large quantity of butter and other dairy produce is exported to England. The keeping of pigs is generally associated with dairy farming, and dairy-fed pork and bacon are highly esteemed.

Sheep Farming. English wool has been famous for centuries, and sheep farming has long been important. Sheep are kept on the hill pastures in all parts of the British Isles, but are more important in Great Britain than in Ireland. Most of the good breeds supply both mutton and wool, but more attention is paid to the quality of the wool in the east, and to the quality of the mutton in the west. The chief sheep-farming districts are the chalk downs of England, the Welsh highlands, and the Southern Uplands of Scotland, particularly the Tweed valley. In Ireland most sheep are found in Carlow, Wicklow, and Galway.

Horse Breeding. Horses require better pasture than sheep, and less rich pasture than cattle. They can therefore be kept in districts which are too dry for cattle. Most of the famous breeds belong to the eastern counties—Yorkshire, Norfolk, Suffolk, Cambridge, and Huntingdon. In Scotland the eastern counties of Fife and Linlithgow are the most important. In Ireland, Dublin, Down, Wexford, and Louth breed most horses.

Fisheries. The shallow seas surrounding Britain, and particularly those off the east coasts, are rich in fish. The Dogger Bank, in the North Sea, is one of the richest fishing-grounds in the world, especially for cod and flat fish. The herring fishery is important round the eastern coasts of Britain, following the movements of the herring, which migrate southwards as the year advances. Pilchards are caught in the Cornish waters. The oyster fishery is important off the eastern coast of England.

Minerals and Metals. Many of the rocks which compose the crust of the earth are of use; granite, for instance, is much quarried for building round Aberdeen. The various sandstones and limestones also make good building stones, and limestone is burned for lime. Slates are quarried in the mountains of Wales, Cumberland, and the North of England generally. Some rocks, like those of Caithness, are used for paving; others, like those of Portland, for cement; and new uses are frequently discovered. In recent years a quarry near Oxford has furnished material for a famous polishing soap. In the plains clay is used for making bricks, or, if of sufficiently fine quality, for pottery.

Coal. Of all the products of the earth's crust coal is at present the most valuable. It is used to generate steam for motive power, and our industries depend on a cheap supply of this indispensable fuel. The coal measures lie above the oldest, but below the younger rocks, and can be worked only when some accident brings them near the surface. In parts of the British Isles the crust of the earth has been thrown into waves by the action of internal forces raising the highland regions. In many of these the upper layers of rock have been worn away in the course of ages, leaving the coal measures exposed in places, so that they can be reached by boring through the surface soil. In the Pennines not merely the younger rocks, but the coal measures also have disappeared from the summit. They remain on both flanks, forming the important coalfields of northern England. Coal is similarly exposed round the eastern and southern margin of the Welsh Highlands, and in some parts of the Midlands. Over most of the English plain the coal measures are buried beneath younger rocks, and cannot be worked. In Scotland the coal measures remain in the trough of the midland plain, forming coalfields which extend almost continuously from the Clyde to the Forth. In Ireland the coal measures have disappeared, except in a few isolated patches. Much of the country is covered with peat bogs, which supply the only available fuel.

Iron and Other Minerals. Next in importance to coal is iron, which occurs in many different forms. The purest quality, known as red hematite, is found in the western Pennines. The less pure, brown hematite, is abundant round the margin of the Welsh Highlands, in Northamptonshire, and in Antrim. Other ores are very common in or near the principal coalfields, the most important being the black band ironstone of Scotland and the ores of the Cleveland hills of Yorkshire.

Lead is worked in the Southern Uplands of Scotland, the Pennines, the mountains of Cumberland, Wales, and the Isle of Man, and in the Wicklow mountains of Ireland. Zinc occurs occasionally along with lead; oil shale is common round Edinburgh; salt is mined in Cheshire, Worcestershire, and Durham, and copper and tin are still worked in Cornwall.

Principal Coalfields of Britain. The coalfields of Britain [69] fall into four groups:

A. The Scottish Coalfields:

1. The Ayrshire Coalfield.
2. The Central, or Forth and Clyde Coalfield.
3. The Fife Coalfield.
4. The Midlothian Coalfield.

The chief manufactures on these coalfields are iron, shipbuilding, and textiles.

B. The Pennine Coalfields:

5. The Northumberland and Durham, associated with the iron manufacture in all its branches, including engineering and shipbuilding, and chemicals.
6. The Cumberland Coalfield, associated with iron-smelting.
7. The South Lancashire Coalfield, associated with the cotton manufacture and with iron and chemical industries.
8. The North Staffordshire Coalfield, associated with the pottery industry.
9. The York, Derby, and Nottingham Coalfield—the richest—associated with woollen, iron, and lace manufactures.

C. The Coalfields round the margin of the Welsh Highlands:

10. The North Wales Coalfield, associated with the manufacture of salt and chemicals.
11. The Middle Severn Coalfield, associated with iron, pottery, and woollen manufactures.
12. South Wales and Forest of Dean Coalfield, chiefly engaged in smelting.

D. The coalfields of the Midland Plain, surrounded by younger rocks:

13. The Midland Coalfield, associated with the iron manufacture.
14. The Bristol Coalfield, associated with the woollen manufacture of the West of England.

All these manufactures are more fully treated in the articles on COMMERCIAL GEOGRAPHY.

THE TOWN-CLERK

Most Responsible Post in the Municipal Service. Qualifications and Salaries. The Town-clerk's Assistants. Clerks of County Councils

By ERNEST A. CARR

THERE is a marked and increasing tendency among local authorities to restrict applications for the position of town-clerk to members of one or other branch of the law. It is found, indeed, that men thus qualified have gained probably 90 per cent. of the posts recently offered for competition.

What the Town-clerk must Know. The town-clerk's is the foremost position on the municipal staff. He is the adviser to his council on innumerable points of law, fact, and practice—in itself no light office, having regard to the multiplicity of important activities carried on by a progressive borough and the scarcely avoidable ignorance of many of the councillors concerning them. He controls a busy department of his own, and is also the official head of the whole staff and the responsible officer for the due execution of the council's orders. At the meetings of his authority, he is the chairman's right-hand man; and having familiarised himself with the details of every important scheme and proposal—when he has not framed them himself—is in a position to advise upon these as they are raised before the council. The acquirement of property and extension of municipal works, "slum area" clearances, and the adoption of statutory powers—on such grave matters as these his judgment is of great weight. His store of law, routine, and precedents must be always at his finger-tips, as it were, for the services of the various heads of departments who constantly consult him. He must be able to draft new bylaws and regulations as need arises, and to handle adequately his council's case at a Local Government Board inquiry, or before a parliamentary commission. An expert within his own particular province, and a point of focus generally between the council and its staff, the town-clerk needs to blend the qualities of the specialist with those of the tactful and patient administrator.

"Most Difficult Post in the Service." All things considered, the following pronouncement of a municipal expert on the duties of the town-clerk seem amply justified:

"It would be rather invidious to make distinctions between the departments, but as regards the town-clerk's, this, whilst performing functions of its own, generally has a kind of supervision over all other departments, such as communicating the instructions of the council and committees to the various chiefs and seeing that the same are punctually obeyed. Of course, every chief must be an expert in his own line; but, writing as one who has had twenty-one years' experience in city, county borough, and large urban district, I should say the most difficult position to fill in the municipal service is that of the town-clerk."

Nevertheless, this authority frankly avows that if he were about to launch his own son on a municipal career, he would select for him the town-clerk's department in preference to all the rest. The fact is that, with all its responsibilities and worries, the possibilities it offers are greater—and earlier attainable—than any other branch, certain engineering posts alone excepted.

Salaries of Town-clerks. In respect of remuneration, the town-clerk's lot is indeed a happy one. As chief staff officer, he generally enjoys the largest salary on the pay-list. The actual range of payment may be readily illustrated by a few typical appointments, which in some instances include special duties, in addition to those of town-clerk.

The City of London, and such leading corporations as Manchester and Glasgow, pay their town-clerks £2,000 a year. In the London boroughs salaries vary generally between £1,000 and £1,250—that at Wandsworth, for instance, being £1,150. Other figures are as follows, the commencing salary alone being given in certain instances:

Newcastle	£1,500
Leicester	£1,500
Bolton, £650, rising by £50 annually to	£1,000
Burnley .. .. ..£700 to	£900
Bath	£800
Tynemouth .. .. ..£600 to	£800
Rochdale and Wimbledon, each ..	£700
Exeter	£675
Ayr	£500
Ramsgate, £400, rising by £25 annually (with emoluments) to	£600
Bexhill, £300, by £25 annually to ..	£400

Private practice is, in most of these instances, debarred by the terms of the engagement. Where the appointment is not a whole time one, it is almost invariably given to a solicitor, the salaries paid varying from about £100 a year for small district councils, up to £500 or more for the boroughs, and the person appointed having to provide his own offices and staff. High salaries, in this branch of the service at least, are not confined to the foremost authorities, boroughs of quite moderate importance paying their chief official from £700 to £1,000 or so per annum. Such of the posts named as have recently been offered for competition have been usually restricted to admitted solicitors, or, in Scotland, to law agents and Writers to the Signet. The effect of such a proviso is to limit competition, and to render advancement speedy and sure for solicitors of the requisite ability and training.

Qualifications. It will be evident from what has been said of the town-clerk's duties that a wide experience of municipal matters is of even greater importance than a purely legal training. The average solicitor or barrister of ten years' standing, if suddenly translated to the position of town-clerk, would find his padded office-chair a veritable bed of thorns. Local government work has special requirements which can only be met by years of practice in a municipal office. But men thus qualified often win leading appointments at an early age.

The town-clerkship to the City Corporation, for example, which is perhaps the premier position of its kind in the kingdom, is held by a brilliant young lawyer, who when elected was only 35 years old; yet his previous municipal record included several subordinate positions and some seven years' experience as chief of the Leicester staff. The Rochdale appointment was won by a solicitor of 38, who had also held both deputy and principal rank. The town-clerks of Bolton and Bexhill were but 32 when appointed; and the Tynemouth official, having become a deputy town-clerk at the age of 26, and a town-clerk only a year later, gained his present valuable post when only 30 years of age.

The Best Beginning. We have already seen that a number of town-clerkships are held by barristers and by non-lawyers, and there is nothing to prevent town councils from making similar appointments in the future. But they appear to be increasingly reluctant to do so, and a careful study of many successful town-clerks' careers makes it abundantly clear that in order to enter this branch of the service under favourable auspices it is most desirable that a candidate should begin his training as articled clerk to a solicitor holding an appointment as clerk to a local authority. To a considerable extent at least the town-clerk is made rather than born; and the formula for success may be expressed as ability *plus* municipal training *plus* professional qualification. A further argument in favour of the last item in this formula may be found in the practice followed by many minor authorities of combining the appointments of town-clerk and solicitor in one official.

Not a "Close" Calling. The reader must not conclude, however, from what has been said that town-clerkships form a close preserve, as it were, shut off by a ring-fence from those whose circumstances prohibit their becoming articled clerks in their teens. There is too much wholesome competition in the service to permit of this. A number of men have entered the town-clerk's department as paid junior assistants, and on promotion to the grade of committee clerk, or assistant town-clerk, have shown such aptitude for their work that they have been given their articles under the town-clerk or his deputy whilst retaining their salaried posts. In this way the defect of a non-professional start is most readily cured; but its achievement is only possible by the goodwill of the council and their chief officer, and is too uncertain a method to be desirable, if articles can be obtained earlier in the usual way. Moreover, as many an overworked official has discovered to his cost, it is extremely arduous and difficult to prepare for professional examinations whilst occupied all day with the anxieties of a responsible post. Resolute and energetic men, however, are not debarred by these considerations. Recently a busy Midland corporation promoted to the premier position an official of twelve years' standing who had passed through the grades of junior committee clerk and assistant town-clerk, and whose articles, at the time of his appointment as town-clerk had not expired.

Deputy and Assistant Town-clerks. What has been said on the question of training for town-clerkships renders it unnecessary to discuss at any length the grades from which they are mainly recruited. Assistant and deputy rank are the successive steps by which the majority of principals have ascended to their positions. These subordinate posts are often filled by the promotion of able committee and office clerks, for many of whom they represent the highest positions attainable in the absence of a legal training. On the other hand, a solicitor who has served his articles in a municipal office seldom has any difficulty in obtaining as soon as he is admitted either an assistant town-clerkship in an important borough or a deputyship in a smaller one. His salary in either event will probably begin at £150 or £175, and rise to £300 or £350, with or without the right to practise privately. On securing deputy rank under a busy authority these figures may be doubled at least. Thus, Warrington pays its deputy town-clerk £250 a year, Bolton £350, Bradford £500—rising by £25 yearly to £750—and Manchester £1,000. The higher posts, however, are mostly restricted to qualified solicitors. The Bradford appointment mentioned, for instance, is coupled with the duties of assistant solicitor, and was offered under the following conditions:

"Candidates must be thoroughly experienced in local government law and practice, and have an intimate knowledge of the work of a town-clerk's (or equivalent) department in a large district, including conveyancing and common law, and must also be fully competent to act as advocate in conducting important cases before magistrates, etc."

Clerks to the County Councils. Both in value and in the special training expected of candidates, these posts much resemble town-clerkships, but are naturally far fewer in number. They afford a wide gradation of salary, from the £350 paid by the Isle of Wight to the £2,000 with which the County of London rewards its distinguished clerk. It is usual to advertise vacancies inviting applications from solicitors and barristers only. In practice a candidate who was not well trained in the special requirements of county law and administration would have no chance of success. For these, as for the town-clerk's office, the best training is afforded by a deputyship.

POETRY, FROM MILTON TO COWPER

A Survey of the Chief Works of Milton, Dryden, Pope, Thomson, Gray, Cowper, Burns, and the Minor Poets of the Period

Continued from page 849

By J. A. HAMMERTON

John Milton. The period we are now about to consider is one in which the lessons urged by the critical school of Ben Jonson bore fruit. The greatest name among the poets of the age that witnessed the rise of the Commonwealth and the downfall of the Stuarts is that of the author of "Paradise Lost."

John Milton (b. 1609; d. 1674), "God-gifted organ voice of England," was the son of a scrivener who had been disinherited by his father for changing his faith to that of the Reformers. His early years are thus described in his own words:

"When I was yet a child no childish play
To me was pleasing; all my mind was set
Serious to learn and know, and thence to do
What might be public good; myself I thought
Born to that end, born to promote all truth,
All righteous things."

Though he wrote verses at the age of ten, and paraphrases of the Psalms (including the well-known "Let us with a gladsome mind") as a schoolboy, we find him in the sonnet "On Arriving at the Age of Twenty-three" lamenting his "late spring."

JOHN MILTON

Milton's Early Poems. These were chiefly inspired by the pastoral surroundings of Horton, in Buckinghamshire, where, after leaving Cambridge, Milton spent five years under the parental roof. "L'Allegro" and "Il Penseroso" are mirthful and pensive poems respectively, as their titles imply. In the former occur the familiar lines:

"Quips and cranks and wanton wiles,
Nods and becks and wreathèd smiles."

In the latter is the phrase "the cricket on the hearth" and the oft-quoted reference to

". . . . storied windows, richly dight,
Casting a dim religious light."

"Comus" is a masque, beneath the exquisite allegory of which may be discerned the poet's political bent, and the whole is rich with promise of the work by which its author is most widely known "Lycidas" is an elegiac poem composed in memory of a college friend. It breathes such a contempt for the corrupt holders of ecclesiastical benefices as to make one wonder why it was not made the subject of a Star Chamber "inquiry." Having pondered these poems, the student should read the beautiful lines, "At a solemn music." The works mentioned were composed between the years 1631 and 1637, when, to quote the glowing words of one of the most competent of living critics, Mr. Edmund Gosse, Milton "contributed to English literature about two thousand of the most exquisite, the most perfect, the most consummately executed verses which are to be discovered in the language. This apparition of Milton at Horton," Mr. Gosse goes on to remark, "without associates, without external stimulus, Virtue seeing 'to do what Virtue would by his own radiant light,' this is one of the most extraordinary phenomena which we encounter in our [literary] history."

"Paradise Lost" and "Paradise Regained." The former work is the better, and best known of all his writings. Though owing something, doubtless, to Spenser's "Faëry Queen," it is not only the first English epic; it is unapproached save by Tennyson's "Idylls of the King." There are various forms of this particular class of poetry; its foreign masters are Homer, Vergil, Tasso, Ariosto, and Dante. Milton's original conception was of a drama on the Arthurian legends. Perhaps the Civil War which intervened between the conception and the performance of the work supplied sufficient motive for a theme of a more sublime and solemn character than even those associated with the Round Table. But, as Milton's great editor, Professor Masson, reminds us, Milton inherited, as it were, a subject with which the imagination of Christendom had long been fascinated. "Paradise Lost" is more than the outpouring of a richly-stored mind saturated in the classics and the Bible. It is an epic that has no parallel in our own or in any other language. "It is an epic of the whole human species—an epic of our entire planet, or, indeed, of the entire astronomical universe. The title of the poem, though perhaps the best that could have been chosen, hardly indicates beforehand the full nature or extent of the theme; nor are the opening lines, by themselves, sufficiently descriptive of what is to follow. It is the vast comprehension of the story, both in space and time, that makes it unique among epics, and entitled Milton to speak of it as involving

'Things unattempted yet in prose or rhyme.

It is, in short, a poetical representation, on the authority of hints from the Book of Genesis, of the historical connection between human time and aboriginal or eternal infinity, or between our created world and the immeasurable and inconceivable universe of pre-human existence." Milton's "Ode on the Morning of the Nativity," written in his Cambridge days, conveyed the theory that the pagan gods were fallen angels. "Paradise Lost" deals with the Rebellion in heaven, the Creation, the Temptation, and the Fall. But that Satan is the hero we beg to disbelieve, despite even Professor Masson's dictum. Milton was too full of humanity—witness his twenty years of patriotic service—to idealise the Evil One. It is man himself he sings. Certainly, the deepest interest attaching to both "Paradise Lost" and "Paradise Regained" is inspired by the study of the character of Satan as the tempter of man and the tempter of Christ. But this interest arises from the *object*, or *subject*, of each encounter. The lesson derivable is twofold. On the one hand, we are brought to a consideration of the misuse of a Divinely given freedom; on the other is enforced the conclusion that God is "Grace Abounding" Of "Paradise Lost" Coleridge said that "no one can rise from the perusal of this immortal poem without a deep sense of the grandeur and purity of Milton's soul."

"Samson Agonistes." This was Milton's last work, and is a drama on the Greek model, founded on the Book of Judges, but, as the author expressly states, not designed for the stage. It is the work of one whose cause had been nobly fought for, and hardly lost. The thoughts uttered by Samson came from the heart of the poet who wrote them. The work is severe in style, but derives its highest value from the parallels it offers between the lives of Samson and Milton himself. For our present purpose what we wish especially to emphasise is the importance of the study of Milton's work to all who aspire to the proper and most effective use of their mother tongue. To Milton may be ascribed Spenser's eulogy of Chaucer as "a well of English undefyled." He had, like Achilles, one defect: he had no sense of humour.

Some of Milton's Contemporaries. THOMAS RANDOLPH (b. 1605; d. 1634) need not detain any but the advanced student. EDMUND WALLER (b. 1605; d. 1687) lives as the author of "Go, lovely Rose" and "Lines on a Girdle," lyrics which, as Waller's latest editor, Mr. Thorn Drury, says, "might almost be chosen from English literature to serve as the examples of the charms of simplicity and directness." SIR JOHN SUCKLING (b. 1609; d. 1642) is save . from oblivion by a song, "Why so pale and wan, fond lover?" and a ballad upon a wedding, beginning, "Her feet beneath her petticoat." SIR RICHARD LOVELACE (b. 1618; d. 1658) is the author of a poem, "To Althea, from Prison," the first two lines of the last stanza of which are fairly common property:

"Stone walls do not a prison make,
Nor iron bars a cage"

RICHARD CRASHAW (b. 1613; d. 1649), a transcendentalist, and author of "The Flaming Heart," is responsible for the familiar phrase "That not impossible she." SIR JOHN DENHAM (b. 1615; d. 1669) is the author of a contemplative poem, "Cooper's Hill," which supplies an early model of the rhythmical couplet. ABRAHAM COWLEY (b. 1618; d. 1667) was another of Dryden's predecessors. To-day Cowley is chiefly read for his prose, though, in his own lifetime, he was one of the most popular poets of the day. He belonged to what Johnson called the "metaphysical" school of Donne, of which we have already heard in our Elizabethan studies. Cowley's "Pindaric Odes" prompted the "Alexander's Feast" of Dryden. SAMUEL BUTLER (b. 1612; d. 1680), in his inimitable satiric poem, "Hudibras," which was written in ridicule of the Puritans, displays much learning as well as wit. ANDREW MARVELL (b. 1621; d. 1678) was a friend of Milton, played the part of laureate during the Protector's life, and wrote a "Horatian Ode upon Cromwell's Return from Ireland," which Trench specially commends to English students of Horace. Marvell's lines on the "Emigrants in the Bermudas" are even better known than the Horatian ode. HENRY VAUGHAN (b. 1621; d. 1693) has been aptly styled a "George Herbert in worsted stockings."

John Dryden. We now come to a name secondary in importance to that of Milton only in the period under review. JOHN DRYDEN (b. 1631; d. 1700) is England's greatest satirist in verse. His influence upon his contemporaries was tremendous. His critical deliverances are reverenced to-day. He excelled as a dramatist and as a writer of prose. For the moment, however, we have to concern ourselves with his poems. One of the first of his characteristics that strikes one is his alertness to the significance of events in the world outside of the library. Witness his "Annus Mirabilis" (the "wonderful year" of 1666), wherein he celebrates the English victories over the Dutch at sea and the benefits of the Great Fire of London.

In "Absalom and Achitophel" Dryden directed the whole weight of his powerful intellect to the undoing of the Earl of Shaftesbury's scheme for inducing Charles II. to nominate his illegitimate son the Duke of Monmouth as his successor to the Throne against the lawful claim of the King's brother James, who was a Romanist. At this time, it should be remembered, Dryden, though soon to adopt the Romish faith (see "The Hind and the Panther"), was strongly Protestant, as may be proved by reference to the work that followed "Absalom and Achitophel"—"Religio Laici." Taking as his model the story of Absalom's revolt against David—as Milton had taken his models from the Bible for "Paradise Lost" and "Samson Agonistes"—Dryden named the various parties to the Monmouth plot after the characters in 2 Samuel. The portrait of Shaftesbury, beginning

"In friendship false, implacable in hate,
Resolved to ruin or to rule the State,"

is the most telling example of passionately concentrated poetic portraiture in our literature.

Dryden's Poetic Power. Three other works by Dryden exhibit his splendid lyrical ability—the "Ode to the Memory of Mrs. Anne Killigrew," described by Johnson as "the noblest in our language," the "Song for St. Cecilia's Day," and "Alexander's Feast." Dryden's translations from Homer, Vergil, Ovid, Juvenal, and Boccaccio, are subjects for advanced study. One of his chief claims to our attention is that directness and masculine vigour of his language which almost any half-dozen lines of his verse would illustrate. "Amid the rickety sentiment looming big through misty phrase which marks so much of modern literature," writes James Russell Lowell, "to read Dryden is as bracing as a north-west wind. He blows the mind clear. In ripeness of mind and bluff heartiness of expression he takes rank with the best. His phrase is always a short cut to his sense. He had beyond most the gift of the right word; and if he does not, like one or two of the Greek masters of song, stir our sympathies by that indefinable aroma, so magical in arousing the subtle associations of the soul, he has this in common with the few great writers that the winged seeds of his thought imbed themselves in the memory, and germinate there."

JOHN DRYDEN

ALEXANDER POPE

WILLIAM COWPER

ROBERT BURNS

The Principal Poets between Dryden and Pope. JOHN OLDHAM (b. 1653; d. 1683), the son of a Nuneaton Nonconformist, was a writer of trenchant satires against the Jesuits. MATTHEW PRIOR (b. 1664; d. 1721) wrote a clever parody of Dryden's "The Hind and the Panther," called "The Country and the City Mouse." His muse, as Hazlitt says, was "a wanton flirt." His poems and lyrics are marked by an easy air of abandonment, but have at least the merit of originality as well as wit. JOSEPH ADDISON (b. 1672; d. 1719) wrote poems and a tragedy, "Cato," which Voltaire greatly admired, but his views on poets—his work, for example, in popularising Milton—and his essays, are the chief things by which he is known to-day.

NICHOLAS ROWE (b. 1674; d. 1718) translated Lucan's "Pharsalia," and wrote the still effective drama of "Jane Shore," but is best remembered as a biographer and editor of Shakespeare.

THOMAS PARNELL (b. 1679; d. 1718), author of "The Hermit" and "The Fairy Tale," aided Pope in his translation of the "Iliad," and wrote an "Elegy to an Old Beauty," of which one line is often quoted:

> "We call it only pretty Fanny's way."

EDWARD YOUNG (b. 1683; d. 1765) was a far from admirable character. His "Night Thoughts" have all the gloom but little of the grandeur of "otherworldliness." JOHN GAY (b. 1685; d. 1732) was the author of several delightful songs. "'Twas when the seas were roaring," "Molly Mog," "Sweet William's Farewell to Black-eyed Susan," are among them.

Alexander Pope (b. 1688; d. 1744). Pope tells us that

> "As yet a child, now yet a fool to fame,
> I lisp'd in numbers, for the numbers came."

Many critics maintain that they came too easily. These are they who hold that Pope's polish is as much a proof of his unpoetic soul as Whitman's ruggedness of his. Pope was obviously influenced by Dryden. But Mr. Gosse insists on Pope's great indebtedness to Boileau. "The French satirist had recommended polish, and no one practised it more thoroughly than Pope did. Boileau discouraged love poetry, and Pope did not seriously attempt it. Boileau paraphrased Horace, and in so doing formulated his own poetical code in 'L'Art Poetique'; Pope did the same in the 'Essay on Criticism.'" Mr. Gosse carries the parallel much further, though this goes far indeed, and English poetry must admit a great debt to the French writer who, at an important moment in its development, inculcated in his English pupil purity and decency of phrase. Pope has a special interest for readers of the SELF-EDUCATOR. The son of a London linen merchant, he was excluded from public school and university by reason of his father's religion; and the result was that he was largely self-taught and self-cultivated.

Pope's Characteristics. What did he do? Much by which we are able to judge his time. "He did, in some not inadequate sense," writes Lowell, "hold the mirror up to Nature.

It was a mirror in a drawing-room, but it gave back a faithful image of society, powdered and rouged, to be sure, and intent on trifles, yet, still, as human in its own way as the heroes of Homer in theirs." His work contains great thoughts. They are for the most part gems not of his own mind but gems reset, admittedly with skill, and therefore of permanent value to those unfamiliar of their origin. He was a poet of infinite descriptive ability and some eloquence, chiefly satirical. Like Byron, he was a cripple; and his affliction affected his outlook on the world. His "Essay on Criticism" was written out in prose before he was twenty years old, and then versified. It has been described as "unquestionably the finest piece of argumentative and reasoning poetry in the English language." Professor Spalding says: "None of his works unites more happily regularity of plan, shrewdness of thought, and beauty of verse." For "beauty" read clarity and vigour. The "Essay" is the one work of Pope's with which the young writer should make himself familiar. Professor Courthope has invited attention to the remarkable analogy presented by the poetical career of Pope to the contemporary change in the English Constitution and the parallel ascendancy of Walpole in politics; and maintains that Pope "gave to the couplet as inherited from Dryden a polish and balance which perfected its capacities of artistic expression, perhaps at the expense of its native vigour." Judged by what he was and what he did, not by what other poets were and by what *they* did, Pope will be found to fill a definite and not undistinguished position in the evolution of English letters as they reflect English life.

Thomson, Gray, and Goldsmith. In the poetry of JAMES THOMSON (b. 1700; d. 1748) is heard an echo of that of Spenser. This echo is characteristic of much of the poetry of the eighteenth century. Thomson affords relief from the works of Pope by singing of Nature sincerely, if in a somewhat affected style. His chief poems are "The Seasons" and "The Castle of Indolence," which prepare the way for the beautiful odes of WILLIAM COLLINS (b. 1721; d. 1759) and the scholarly writings of THOMAS GRAY (b. 1716; d. 1771), whose "Elegy written in a Country Churchyard" (Stoke Poges) did for "the rude forefathers of the hamlet" what Pope accomplished for the fashionable folk of the town. Gray wrote little, but what he wrote was written supremely well. He was a man of leisure and refinement, the son—like Milton—of a scrivener. He drew inspiration from Milton and Dryden, and is one of the harbingers of Wordsworth. Mention may here be made of ROBERT BLAIR (b. 1699; d. 1746), who wrote a sombre poem called "The Grave"; WILLIAM SHENSTONE (b. 1714; d. 1763), whose "Schoolmistress" is a tender tribute to a Leasowes teacher, Sarah Lloyd; MARK AKENSIDE (b. 1721; d. 1770), whose "Pleasures of the Imagination" is a poem too dull and too didactic in character to appeal to the modern reader; and OLIVER GOLDSMITH (b. 1728; d. 1774), a name universally beloved—and, in truth, that of a citizen of no one country, but of the world. Let none apply too scornfully or carelessly the term "bookseller's hack," for Goldsmith—poet of "The Deserted Village," writer of that inimitable novel, "The Vicar of Wakefield," and author of the equally delightful comedy, "She Stoops to Conquer"—was a bookseller's hack. Goldsmith had, in generous measure, the saving grace of humour, with infinite tenderness and graceful delicacy of thought. "No writer in the language," says Professor Masson, "has ever surpassed him, or even equalled him, in that witching-simplicity, that gentle ease of movement, sometimes careless and slipshod, but always in perfect good taste, and often delighting with the subtlest turns and felicities, which critics have admired for a hundred years in the diction of Goldsmith." In some respects he touches the heart of man, and especially of the literary man, more surely even than Charles Lamb does. Ireland, that gave us a Swift, also gave us Oliver Goldsmith. The fact is one to be held perpetually in grateful remembrance.

William Cowper (b. 1731; d. 1800). Cowper makes his appeal to young England in the nursery. Where is the English child who has not treasured the ballad of "John Gilpin"? Cowper missed the sweet influences of a mother's love. He laboured from infancy under the disabilities of a weakly frame, and for a time under the terrible burden of insanity. His first masters were Milton and Cowley; his music was also inspired by the works of Thomson. His initial essays in verse were written under the personal influence of the Rev. John Newton, curate of Olney, in Buckinghamshire, a man of melancholic temperament and a converted slave-trader. Cowper's sad experiences of public school life are reflected in his "Tirocinium; or, a Review of Schools." How his famous didactic poem, "The Task," came to be written makes a charming story of woman's influence. Cowper, cheered by the sympathetic friendship of Lady Austen, had written the ballad of "John Gilpin," after Lady Austen had recounted the legend to him; and she then asked him why he did not try blank verse. "I will," he replied, "if you will give me a subject." "Oh," was the rejoinder, "you can write on any subject. Write on this sofa." This was the germ from which sprang "The Task." Thus succinctly Arnold has indicated Cowper's treatment of Lady Austen's theme: "After having come down to the creation of the sofa, fancy bears him away to his school days [at Westminster], when he roved along Thames' bank till tired, and needed no *sofa* when he returned; then he becomes dreamy, traces his life down the stream of time to the present hour, noting what has made him happy, stilled his nerves, strengthened his health, raised his spirits, or kept them at least from sinking; and finds that it has been ever the free communion with Nature in the country." Many charming descriptive passages are interwoven in all this.

It is in "The Task" that is found the often-quoted line:

"God made the country, and man made
the town."

Cowper's Contemporaries. Among these were James Macpherson (b. 1736; d. 1796), the reputed author of "Ossian"; Charles Churchill (b. 1731; d. 1764), author of the satirical "Prophecy of Famine"; Michael Bruce (b. 1746; d. 1767), who wrote that delightful lyric, "Ode to the Cuckoo"; and Thomas Chatterton (b. 1752; d. 1770), who wrote the "Rowley Forgeries" at the age of sixteen,

"The marvellous boy,
The sleepless soul that perished in his pride!"

Chatterton came to London full of hope and confidence in his extraordinarily precocious powers. He died of starvation and poison in a wretched garret, and was buried in the paupers' pit of Shoe Lane Workhouse.

Robert Burns (b. 1759; d. 1796). Scotland's national bard was a poet of the people, who wrote for the people. It was Professor Blackie who declared on his deathbed, "The Psalms of David and the Songs of Burns—but the Psalmist first." These words, said Lord Rosebery on a memorable occasion at Paisley (1896), contain the secret of many a Scottish character. "To Burns," said Lord Rosebery, "we owe it that we canny, long-headed Scots do not stagnate into prose. His genius and character are the Gulf Stream which prevents our freezing into apathy and material life. . . He never fails us. We rally regularly and constantly to his summons and his shrine. His lute awakens our romance, and charms the sunless spirits of darkness. He is the influence that maintains an abiding glow in our dour character." Burns followed no "master" and founded no "school." He stands alone, and in his own domain is without a rival. For the best interests of literature let the young student study such poems as "The Cotter's Saturday Night," "To Mary in Heaven," "To a Mountain Daisy," "Robert Bruce's Address to His Army," "To a Mouse," "Hallowe'en," "Tam o' Shanter," and "The Jolly Beggars," and leave the story of the poet's life for more mature consideration. From the works named may be gained sufficient insight into the humanity, the humour, the pathos, and the lyrical genius of their author. The songs of Burns must appeal to all. They are rich and rare. "The Banks o' Doon," "Green Grow the Rashes O," "The Birks of Aberfeldy," "John Anderson," "Highland Mary," "My Heart's in the Highlands," "Auld Lang Syne," "For a' That and a' That," "The Lass o' Ballochmyle"—these are part of every Scotsman's birthright. But the poetry of Burns is not only a Scottish possession, it enters into the school courses and plays no insignificant part in the formation of the British character.

RATIO AND PROPORTION

Chain Rule. Unitary Method. Proportional Parts. Percentage. Profit and Loss. Examples and Answers

By HERBERT J. ALLPORT, M.A.

105. *The ratio of one quantity to another of the same kind is the number of times the first* [illegible] whole number or a fraction.

Since we use division to find how many times one quantity is contained in another, the ratio of two quantities is expressed thus $\frac{\text{1st Quantity}}{\text{2nd Quantity}}$, or thus, 1st Quantity : 2nd Quantity, the notation in the second case being an abbreviation of 1st Quantity ÷ 2nd Quantity. Hence, we see that to find the ratio of one quantity to another we have simply to express the first as the fraction of the second, exactly as in Art. **92**. The ratio of 3 furlongs to 5 miles is $\frac{3}{40}$, since this is the result we get, on reducing 3 furlongs to the fraction of 5 miles. Evidently, the quantities must be "of the same kind." There is no ratio between 2 tons and 5 sovereigns, for 2 tons cannot be expressed as a fraction of 5 sovereigns.

106. The two quantities which form a ratio are called the *terms* of the ratio. The first term is called the *antecedent*, and the second the [illegible]

Since the numerator and denominator of a fraction may both be multiplied or both divided by the same quantity, it follows that the terms of a ratio may both be multiplied, or both divided by the same quantity without altering the value of the ratio.

107. Four quantities are said to be in *proportion* when the ratio of the first to the second equals the ratio of the third to the fourth.

Example **1**. 2, 3, 12, 18 are in proportion, since $\frac{2}{3} = \frac{12}{18}$.

Example **2**. 7 men, 5 men, 3s. 6d. and 2s. 6d. form a proportion. For the ratio of 7 men to 5 men $= \frac{7}{5}$, and the ratio of 3s. 6d. to 2s. 6d. $= \frac{\text{3s. 6d.}}{\text{2s. 6d.}} = \frac{\text{7 sixpences}}{\text{5 sixpences}} = \frac{7}{5}$.

The proportion is expressed by writing the sign ∷ or the sign = between the two ratios.

Thus, 7 men : 5 men ∷ 3s. 6d : 2s. 6d.
or, 7 men : 5 men = 3s. 6d. : 2s. 6d.

Either expression is read thus: "7 men is to 5 men as 3s. 6d. is to 2s. 6d."

Since the first two terms of a proportion form a ratio, they must be quantities of the same kind. Similarly, the third and fourth terms must be of the same kind.

The first and last terms of a proportion are called the *extremes*, the second and third are called the *means*.

108. In any proportion, the product of the extremes equals the product of the means.

Consider the proportion 21 lb. : 1 cwt. ∷ 1s. : 5s. 4d.

The first ratio is $\frac{\text{21 lb.}}{\text{1 cwt.}} = \frac{21}{112}$. The [illegible] $\frac{\text{1s.}}{\text{5s. 4d.}} = \frac{12}{64}$. The proportion states that $\frac{21}{112} = \frac{12}{64}$.

If we now multiply each of these fractions by 112 × 64, we obtain 21 × 64 = 112 × 12. That is, the product of the extremes equals the product of the means. Any other case can be proved in the same way.

109. The application of proportion to the solution of problems depends entirely on the property just proved; for, by means of it, we can, when we know any three terms of a proportion, find the remaining term.

Example **1**. Find the third term of a proportion in which the first, second, and fourth terms are 7, 11, 77.

The product of the first and last terms = 7 × 77.

Hence, the product of the second and third also = 7 × 77. But the second term is 11.

∴ The third term $= \frac{7 \times 77}{11} = \underline{49\ \textit{Ans.}}$

Example **2**. Find a fourth proportional to 21 yd., 8 yd., 42s.

[illegible] means = 8 × 42.

The first term is 21; therefore the fourth $= \frac{8 \times 42}{21} = 16$; and, since the third term is 42 *shillings* the fourth term = $\underline{\text{16s. } \textit{Ans.}}$

110. We shall now solve one or two problems by the aid of proportion.

Example **1**. If 1 ton 5 cwt. of coal cost £1 11s. 3d., what will be the cost of 3 tons 5 cwt.?

EXPLANATION. We make our "answer" the fourth term of the proportion. Now, the third and fourth terms must be of the same kind (Art. **107**). Hence, since our fourth term is to be a "cost," so also must our third term. We see, then, that £1 11s. 3d. must be taken for our third term. It only remains for us to determine which of the two other terms, viz., 1 ton 5 cwt. and 3 tons 5 cwt., is the first term and which the second. To do this we ask ourselves the question: "Will 3 tons 5 cwt. cost more or less than 1 ton 5 cwt.?" Evidently, it will cost more; so that the answer we are seeking is greater than £1 11s 3d.—*i.e.*, the fourth term is greater than the third. It follows that the second term must be greater than the first. Therefore, we are able to *state* our proportion, thus:

1 ton 5 cwt. : 3 tons 5 cwt. ∷ £1 11s. 3d. : Ans.

We must now reduce the first and second terms to the same denomination (since a *ratio* is a *fraction*, and to express one quantity as a fraction of another we must reduce them to terms of the same unit). The answer is then obtained by multiplying together the second and third terms, and dividing by the first (Art. 109). Since the product of the second and third terms forms the numerator of our answer, and the first term forms the denominator, it is clear that we may cancel common factors of the first and third terms, or of the first and second, but *not* of the second and third.

The work finally appears thus :

1 ton 5 cwt. : 3 tons 5 cwt. : : £1 11 3 : Ans.
20 20 13
$\cancel{25}$ cwt. $\cancel{65}$ cwt. 5)20 6 3
5 13 £4 1 3 *Ans.*

Example **2**. If a certain pasture lasts 56 sheep 24 days, how long will it last 64 sheep ?

Here, the term which is of the same kind as the required answer is 24 days. Put 24 days for the third term. Next, ask the question " Will 64 sheep be able to graze for a longer or shorter period than 56 sheep ? Evidently, since there are *more* sheep, the pasture will last *less* time. The second term must, therefore, be less than the first.

Hence,

64 sheep : 56 sheep : : 24 days : Ans.

$$\therefore \text{ Ans. } \frac{\overset{3}{\cancel{24}} \times \overset{7}{\cancel{56}}}{\underset{8}{\cancel{64}}} \text{ days } \underline{\underline{21 \text{ days.}}}$$

111. Such questions as the above, in which we are given three quantities and required to find a fourth, belong to *Simple* Proportion. We shall now consider questions of a like nature, but having more quantities involved, and thus requiring more than one application of the rule in order to solve them. Such questions belong to *Compound* Proportion.

Example **1**. The carriage of 36 lb. for 45 miles is 6s. 9d. How far will 58 lb. be carried for 14s. 6d. ?

We first consider the following question : " If 36 lb. be carried 45 miles for 6s. 9d., how far will 36 lb. be carried for 14s. 6d. ? " The 36 lb. carried, being the same in each case, cannot affect the question. Therefore, we have 6s. 9d. : 14s. 6d. : : 45 miles : required distance.

$$\text{Hence, this distance} = \frac{45 \times 14\text{s. } 6\text{d.}}{6\text{s. } 9\text{d.}} \text{ miles,}$$

$$= \frac{45 \times 174}{81} \text{ miles.}$$

We next ask, " If 36 lb. be carried $\frac{45 \times 174}{81}$ miles for 14s. 6d. how far will 58 lb. be carried for 14s. 6d." Here, the 14s. 6d. does not affect the question, and we have (since *more* lbs. will be carried a *less* distance),

$$58 \text{ lb. : } 36 \text{ lb. : : } \frac{45 \times 174}{81} \text{ miles : Ans.}$$

$$\therefore \text{ Ans.} = \frac{\overset{5}{\cancel{45}} \times \overset{3}{\cancel{174}} \times \overset{4}{\cancel{36}}}{\cancel{81} \times \cancel{58}} \text{ miles} = \underline{\underline{60 \text{ miles.}}}$$

We see, then, that the given distance, 45 miles, has to be changed in the ratio formed by multiplying together the two ratios $\frac{174}{81}$ and $\frac{36}{58}$.

The ratio formed by multiplying together two or more ratios is called the ratio *compounded* of those ratios.

It may be expressed by writing the separate ratios under one another and bracketing them together.

The above example would then be stated as follows :

$$\left.\begin{array}{l} 6\text{s. } 9\text{d. : } 14\text{s. } 6\text{d.} \\ 58 \text{ lb. : } 36 \text{ lb.} \end{array}\right\} \text{ : : } 45 \text{ miles : Ans.}$$

and the answer is obtained by multiplying the third term by all the second terms, and dividing by all the first terms.

Example **2**. If 25 men dig a trench 210 yd. long, 4 yd. wide, 2 yd. deep in 315 days of 8 hours each, in how many days will 150 men dig a trench 280 yd. long, 3 yd. wide, and 3 yd. deep, working 10 hours a day ?

First, pick out the quantity which is of the same sort as the required answer, *i.e.*, 315 days. This is our third term. We now ask a series of questions, referring always to this 315 days.

(i) If 25 men take 315 days, how long will 150 men take ? Less. Therefore, first ratio is 150 men : 25 men.

(ii) If 210 yd. length takes 315 days, how long will 280 yd. length take ? More. Therefore, second ratio is 210 yd. : 280 yd.

(iii) If 4 yd. width takes 315 days, how long will 3 yd. width take ? Less. Hence, 4 yd. : 3 yd.

(iv) Similarly, considering the depth, we get 2 yd. : 3 yd., and (v) considering length of day, we get 10 hours : 8 hours Hence, our statement is,

$$\left.\begin{array}{rcl} 150 \text{ men} & : & 25 \text{ men} \\ 210 \text{ yd.} & : & 280 \text{ yd.} \\ 4 \text{ yd.} & : & 3 \text{ yd.} \\ 2 \text{ yd.} & : & 3 \text{ yd.} \\ 10 \text{ hr.} & : & 8 \text{ hr.} \end{array}\right\} \text{ : : } 315 \text{ days : Ans.}$$

∴ Required number of days

$$= \frac{\overset{63}{\cancel{315}} \times \cancel{25} \times \overset{4}{\cancel{280}} \times \cancel{3} \times \cancel{3} \times 8}{\underset{\underset{\cancel{2}}{\cancel{6}}}{\cancel{150}} \times \underset{\cancel{3}}{\cancel{210}} \times \cancel{4} \times \cancel{2} \times \underset{\cancel{2}}{\cancel{10}}} \quad \underline{\underline{63 \text{ days } \textit{Ans.}}}$$

CHAIN RULE

112. Suppose we have a series of quantities of different kinds, with a given relation between the first and second, between the second and third, and so on. We find the relation between the first quantity and the last quantity by a method known as *Chain Rule*.

Example 1. If 3 turkeys are worth 5 geese, 4 geese are worth 11 ducks, 3 ducks are worth 4 fowls, and a pair of fowls costs 6 shillings, find the value of a turkey.

Using the sign = to denote " are worth," we have

Required value (in shillings) = 1 turkey.
3 turkeys = 5 geese.
4 geese = 11 ducks.
3 ducks = 4 fowls.
2 fowls = 6 shillings.

Thus, the same denominations (shillings, turkeys, etc.), occur on the left as occur on the right. Therefore, the product of the *numbers* on the left will equal the product of the *numbers* on the right ; from which we obtain

$$\text{Required value} = \frac{1\times5\times11\times\cancel{4}\times\cancel{6}}{3\times\cancel{4}\times\cancel{3}\times\cancel{2}}\text{ shillings}$$

$$= \frac{55}{3} = \underline{18\text{s. }4\text{d. }\textit{Ans.}}$$

Example 2. In a mile race A beats B by 66 yd. B beats C by 80 yd. By how much does A beat C ?

Here, A goes 1760 yd. while B goes 1760 - 66, or 1694 yd. B goes 1760 yd. while C goes 1760 - 80, or 1680 yd.

Arranging the work as in Ex. 1, we have

A's 1760 = B's 1694
B's 1760 = C's 1680
Reqd. C's = A's 1760

$$\therefore\ \text{C goes } \frac{\overset{77}{\cancel{1694}}\times\overset{21}{\cancel{1680}}\times\cancel{1760}}{\underset{22}{\cancel{1760}}\times\cancel{1760}}\text{ yd.} = 1617\text{ yd.}$$

$\therefore$ A beats C by 1760 - 1617 = 143 yd. *Ans.*

UNITARY METHOD

113. All the examples considered in Arts. 110-112 may be solved by the *Unitary Method.* Such a method is neat enough when applied to problems in simple proportion, but is not to be recommended in other cases. We shall, however, work out Example 2 of Art. 110, and Example 1 of Art. 111, to illustrate it.

Example 2, Art. 110. If a certain pasture lasts 56 sheep for 24 days, how long will it last 64 sheep ?

Pasture lasts 56 sheep for 24 days.

$\therefore$ It lasts 1 sheep for 24 × 56 days.

$\therefore$ It lasts 64 sheep for

$$\frac{24\times56}{64}\text{ days} = \underline{21\text{ days }\textit{Ans.}}$$

Example 1, Art. 111. The carriage of 36 lb. for 45 miles is 6s. 9d. How far will 58 lb. be carried for 14s. 6d. ?

For 6s. 9d. 36 lb. is carried 45 miles.

$\therefore$ For 1d. 36 lb. is carried $\frac{45}{81}$ miles.

$\therefore$ For 1d. 1 lb. is carried $\frac{45\times36}{81}$ miles.

$\therefore$ For 14s. 6d. 1 lb. is carried

$$\frac{45\times36\times174}{81}\text{ miles.}$$

$\therefore$ For 14s. 6d. 58 lbs. is carried

$$\frac{45\times36\times174}{81\times58}\text{ miles} = \underline{60\text{ miles }\textit{Ans.}}$$

PROPORTIONAL PARTS

114. It is often required to divide a given quantity into parts proportional to given numbers. The method of working will be understood from the following examples :

Example 1. Divide £8 12s. 6d. into three parts proportional to 2, 3, and 5.

Since 2 + 3 + 5 = 10, it is evident that if we divide the sum of money into 10 equal portions, the three parts required will consist respectively of 2, 3, and 5 of these portions.

Now, £8 12s. 6d. ÷ 10 = 17s. 3d.

$\therefore$ The three parts required are

$$\left.\begin{aligned}17\text{s. }3\text{d.}\times2 &= £1\ 14\text{s. }6\text{d.}\\ 17\text{s. }3\text{d.}\times3 &= £2\ 11\text{s. }9\text{d.}\\ \text{and }17\text{s. }3\text{d.}\times5 &= £4\ \ 6\text{s. }3\text{d.}\end{aligned}\right\}\ \underline{\textit{Ans.}}$$

Example 2. Three men, A, B, and C, rent a field for £24 9s. 2d. A grazes 23 cattle for 17 days, B grazes 27 for 15 days, and C 21 for 18 days. How much of the rent should each pay ?

A's 23 cattle for 17 days require as much as 23 × 17 cattle for 1 day = 391 for 1 day.

Similarly, B uses as much as 27 × 15 = 405 for 1 day.

And C uses as much as 21 × 18 = 378 for 1 day.

The rent should, therefore, be divided in the proportion of 391, 405, and 378.

Now 391 + 405 + 378 = 1174.

Therefore, A should pay

$$\frac{391}{1174}\text{ of £24 9s. 2d.} = 391\times\frac{5870\text{d.}}{1174} = 391\times5\text{d.}$$

$$\left.\begin{aligned}&= £8\ \ 2\text{s. }11\text{d.}\\ \text{B should pay }405\times5\text{d.} &= £8\ \ 8\text{s. }\ 9\text{d.}\\ \text{C should pay }378\times5\text{d.} &= £7\ 17\text{s. }\ 6\text{d.}\end{aligned}\right\}\ \underline{\textit{Ans.}}$$

Example 3. Three boys, A, B, and C, divide 10726 nuts between them. As often as A takes 4, B takes 5, and as often as B takes 3, C takes 7. Find the number each boy has.

A's share : B's share = 4 : 5.
B's share : C's share = 3 : 7.

The numbers representing B's share in the two ratios are 5 and 3. The L.C.M. of 5 and 3 is 15. Therefore, multiply the first ratio by 3 and the second by 5, in order to make B's share be represented by the same number, 15, in each ratio. We thus obtain

A's share : B's : C's = 12 : 15 : 35.

$\therefore$ A has

$$\frac{12}{12+15+35}\text{ of the nuts} = \frac{12}{62}\text{ of }10726$$

$$\left.\begin{aligned}&= 12\times173 = 2076\\ \text{B has }15\times173 &= 2595\\ \text{C has }35\times173 &= 6055\end{aligned}\right\}\ \underline{\textit{Ans.}}$$

EXAMPLES 14

1. A man whose stride is 30 in. takes 3120 steps to go a certain distance. How many steps will a man whose stride is 2 in. longer take to go the same distance ?

2. A garrison of 5000 men has provisions for 137 days. After 50 days it is reinforced by 800 men. How many more days will the provisions now last ?

3. A man contracts to do a piece of work in 48 days, and employs 20 men. He finds, at the end of 36 days, that only half the work is finished. How many extra men must he now engage in order to fulfil the contract ?

4. When candles are 6 to the pound, each candle burns 6 hours. How long will a candle burn when they are 8 to the pound ?

5. In a certain village 2 women in every 5, and 4 men in every 9, are unmarried. There are 24 unmarried women, and the total number of men is to the total number of women in the ratio 3 : 4. Find the number of married men.

6. A cask was filled with wine and water mixed together in the ratio 5 : 3. When 16 gallons of the mixture had been drawn off, and water put in instead, the ratio of wine to water was 3 : 5. How many gallons did the cask hold ?

7. If the carriage of 72 cwt. for 15 miles is £2 5s., how far will 5 cwt. be carried for half-a-crown ?

8. If 4 men or 8 women can plant a field of 5 acres in 3½ days, working 10 hours a day, how long will it take 2 men and 3 women to plant 8 acres working 12 hours a day ?

9. The first of 4 boys can copy 4 pages while the second copies 5, the second does 6 while the third does 7, and the third does 3 while the fourth does 2. How many pages will the fourth boy copy while the first boy does 18 pages ?

10. In a 100 yd. race A beats B by 1 yd. B beats C by 1½ yd. in 120 yd. By how much will A beat C in a mile, supposing A, B, and C to always run at the same rates ?

11. A heap of 126 coins consists of half-crowns, florins, and shillings ; the values of the half-crowns, florins, and shillings are as 2 : 3 : 4. How many shillings are there ?

12. If 100 men can make an embankment 55 yd. long, 20 ft. wide, and 5 ft. high in 4 days, working 11 hours a day, how many will be required to make an embankment 120 yd. long, 25 ft. wide, and 4 ft. high, in 5 days, working 12 hours a day ?

PERCENTAGE

115. The expression "per cent.," which is an abbreviation of the Latin words "per centum," means "for each hundred."

The symbol % is often used to denote "per cent." Thus, 7 per cent., or 7%, means 7 parts out of every 100 parts, *i.e.*, $\frac{7}{100}$ of the whole.

The *number* per cent. is called the *rate* per cent.

116. Clearly, then, a percentage of a given quantity can always be expressed as a vulgar fraction of that quantity. In some cases the corresponding vulgar fractions are so simple that it is advisable to remember them. For example:

$$25\% = \frac{25}{100} = \frac{1}{4}, \qquad 50\% = \frac{50}{100} = \frac{1}{2},$$

$$75\% = \frac{75}{100} = \frac{3}{4}, \qquad 33\tfrac{1}{3}\% = \frac{33\frac{1}{3}}{100} = \frac{1}{3},$$

$$66\tfrac{2}{3}\% = \frac{66\frac{2}{3}}{100} = \frac{2}{3}, \qquad 5\% = \frac{5}{100} = \frac{1}{20},$$

$$2\tfrac{1}{2}\% = \frac{2\frac{1}{2}}{100} = \frac{1}{40}, \qquad 12\tfrac{1}{2}\% = \frac{12\frac{1}{2}}{100} = \frac{1}{8},$$

and so on.

Again, since 5% = $\frac{1}{20}$, 5% of £1 = 1s. Therefore, 5 per cent. of any sum of money is "1s. in the £." Similarly, 2½ per cent. of a sum of money is "6d. in the £."

117. To find any required percentage of a given quantity, express the percentage as a vulgar fraction, and take that fraction of the given quantity.

Example 1. Find the value of 7 per cent. of 35 tons.

7 per cent. = $\frac{7}{100}$.

Hence

$$\begin{array}{r} 35 \text{ tons} \\ 7 \\ \hline 2{\cdot}45 \text{ tons} \\ 20 \\ \hline 9{\cdot}00 \text{ cwt.} \end{array}$$

2 tons 9 cwt. *Ans.*

Conversely, to find what percentage one quantity is of another, reduce the first quantity to the fraction of the second [Art. **92**], and take that fraction of 100.

Example **2.** A tradesman deducts 3s. 6d. from an account for £5 16s. 8d. as "discount for cash." What rate per cent. does he allow ?

$$\text{Required rate per cent.} = \frac{3s.\ 6d.}{£5\ 16s.\ 8d.} \text{ of } 100$$

$$= \frac{42}{1400} \text{ of } 100 = 3\%\ \textit{Ans.}$$

PROFIT AND LOSS

118. When a thing is sold for more than it cost the seller, it is said to be sold at a *profit*. If it is sold for less than the cost, it is sold at a *loss*. Hence,

Profit = Selling Price − Cost Price.
Loss = Cost Price − Selling Price.

A profit, or loss, is generally reckoned as a percentage.

It is always understood that *the percentage is reckoned on the cost price.*

Thus, if an article which costs 9d. is sold for 1s., the seller gains 3d. on an outlay of 9d., *i.e.*, he gains $\frac{3}{9}$, or $\frac{1}{3}$ of his outlay. His gain per cent. is, therefore, $\frac{1}{3}$ of 100, or 33⅓ per cent.

A common mistake is to say that he gains 3d. on 1s., *i.e.*, $\frac{1}{4}$ of 100 per cent., or 25 per cent.

119. The types of questions met with in Profit and Loss, and the methods of solving them, will be understood from the following examples:

Example 1. A merchant buys 56 gallons of wine for £58 6s. 8d., and sells it at 21s. 8d. a gallon. What is his gain or loss per cent. ?

$$\text{He buys 1 gallon for } \frac{£58\ 6s.\ 8d.}{56} = £1\ 0s.\ 10d.$$

He sells 1 gallon for £1 1s. 8d.

Therefore, he gains £1 1s 8d. − £1 0s. 10d., *i.e.*, 10d., on an outlay of £1 0s. 10d., or 250d.

His gain per cent. is, therefore,

$$\frac{10}{250} \text{ of } 100 = 4\%\ \textit{Ans.}$$

Example 2. A watch was sold for £8 11s. at a loss of 5 per cent. What would have been the gain or loss per cent. had it been sold for 10 guineas ?

The watch is sold for 95 per cent. of its cost. We have, then, a question in simple proportion, viz., "If £8 11s. represents 95 per cent. of the cost, how much per cent. of the cost does £10 10s. represent ?" Whence,

£8 11s. : £10 10s. :: 95% of cost : required percentage.

$$\therefore \text{ Ten guineas represents } \frac{\overset{5}{\cancel{95}} \times \overset{70}{\cancel{210}}}{\underset{\underset{3}{\cancel{9}}}{\cancel{171}}} \text{ per cent. of cost}$$

$= \frac{350}{3} = 116\frac{2}{3}$ per cent. of cost, *i.e.*, there is a *gain* of 16 % *Ans.*

Note that in questions like Ex. 2 it is not necessary to find the cost price.

Example 3. **A jeweller prices a brooch 40 per cent. above cost. He deducts 12½ per cent. for cash, and gains 9s. What did the brooch cost him ?**

A brooch which costs 100 is marked 140, *i.e.*, it is marked at $\frac{140}{100}$, or $\frac{7}{5}$ of its cost.

The jeweller deducts $\frac{12\frac{1}{2}}{100}$ of its marked price, so that he sells it for $\frac{87\frac{1}{2}}{100}$, or $\frac{7}{8}$ of its marked price.

But $\frac{7}{8}$ of marked price = $\frac{7}{8}$ of $\frac{7}{5}$ of cost = $\frac{49}{40}$ of cost = $(1 + \frac{9}{40})$ of cost.

He therefore gains $\frac{9}{40}$ of what it cost him.

Hence, 9s. = $\frac{9}{40}$ of cost.

Therefore, cost = 40s. = £2 *Ans.*

Example 4. If 2½ per cent. more is gained by selling a horse for £75 than by selling it for £73 10s., what did the horse cost ?

The difference in the selling prices = £75 − £73 10s. = £1 10s.

Therefore £1 10s. *is* 2½ *per cent. of the cost price, i.e.*, $\frac{1}{40}$ of the cost price.

Hence, cost price = 40 × £1 10s. = £60 *Ans.*

Example 5. A man sells an article at a profit of 5 per cent. Had he bought it 6¼ per cent. cheaper and sold it for 9d. more than he did, he would have gained 15 per cent. Find the cost price.

If he bought for 6¼ per cent. less, he would pay $\frac{93\frac{3}{4}}{100}$ of what he actually does pay.

To gain 15 per cent. he must sell for $\frac{115}{100}$ of the cost, *i.e.*, he must sell for $\frac{115}{100} \times \frac{93\frac{3}{4}}{100}$ of the actual cost.

$$\frac{\overset{23}{\cancel{115}}}{\underset{\underset{4}{\cancel{20}}}{\cancel{100}}} \times \frac{\overset{\overset{3}{\cancel{15}}}{\cancel{375}}}{\underset{16}{\cancel{400}}} = \frac{69}{64} \text{ of actual cost.}$$

But he really sells to gain 5 per cent., *i.e.*, for $\frac{105}{100}$, or $\frac{21}{20}$ of the cost price. The difference between these selling prices is $(\frac{69}{64} - \frac{21}{20})$ of the cost price, or $\frac{345 - 336}{320} = \frac{9}{320}$ of cost price.

And the question tells us the difference in the selling prices is 9d. Hence, 9d. = $\frac{9}{320}$ of cost price, so that the cost price = 320d. = £1 6s. 8d. *Ans.*

EXAMPLES 15

1. By selling goods for £247 a merchant loses 5 per cent. What ought the selling price to be to gain 7 per cent. ?
2. A man buys a number of oranges at 2 a 1d. and an equal number at 3 for 2d. He sells the whole at 5 for 3d. Find his gain or loss per cent.
3. If 4 per cent. more is lost by selling an article for 9s. 2d. than by selling it for 9s. 7d., how much per cent. is lost in each case ?
4. A shopkeeper bought 750 eggs at 15 a shilling. He broke 13, and after selling the remainder, found that he had lost 2% on his outlay. How many did he sell for a shilling ?
5. 24 lb. of tea worth 1s. 10d. per lb. are mixed with 8 lb. worth 2s. 10d. per lb. At what price per lb. must the mixture be sold in order to make a profit of 10 per cent. ?
6. A man sold a house at a profit of 10 per cent. Had he sold it for £168 less, and bought it 5 per cent. cheaper, he would have gained 4 per cent. For what amount did he sell the house ?
7. A tradesman marks his goods 20 per cent. above cost price, but allows a discount of 7½ per cent. off the marked price. What is his net gain per cent. ?
8. A man sold two houses for £990 each. He gained 10 per cent. on the one, and lost 10 per cent. on the other. Find the amount he gains or loses on the whole transaction.

Answers to Arithmetic

EXAMPLES 12

1. $14{\cdot}096\dot{2}5944\dot{1}$.

2. $21{\cdot}9\dot{2}3\dot{6} - 9{\cdot}\dot{3}89\dot{3} = 12{\cdot}53\dot{4}29\dot{7}$.

3. $2{\cdot}25\dot{2}8571\dot{4} = 2{\cdot}25 + {\cdot}00\dot{2}8571\dot{4} = 2\frac{1}{4} + \frac{2}{700} = 2\frac{44}{175}$.

4. Reduce both sums to halfpence. Then, required fraction = 7527 ÷ 47671 = $\frac{3}{19}$ = $\cdot\dot{1}5789473684210526\dot{3}$. (Apply Art. **96** (3) to obtain the last nine digits of the period.)

5. $\cdot1\dot{3}\dot{6}$ of £7 14s. 11d − $\cdot0\dot{2}\dot{4}$ of £6 0s. 3¾d. = $\frac{3}{22}$ of £7 14s. 11d. − $\frac{7}{275}$ of £6 0s. 3¾d. = £1 1s. 1½d. − 3s. 0¾d. = 18s. 0¾d.

6. $\cdot7\dot{3}$ of $1{\cdot}\dot{2}3\dot{4}$ of 12 = $\frac{11}{15}$ of $14{\cdot}8\dot{1}\dot{0}$ = 11 × $\cdot9\dot{8}7\dot{3}$ = $10{\cdot}8\dot{6}1\dot{2}$.

7. $\frac{2}{7} = \cdot\dot{2}8571\dot{4}$; $\frac{1}{7} = \cdot\dot{1}4285\dot{7}$; $\frac{3}{7} = \cdot\dot{4}2857\dot{1}$; $\frac{4}{7} = \cdot\dot{5}7142\dot{8}$; $\frac{6}{7} = \cdot\dot{8}5714\dot{2}$; $\frac{5}{7} = \cdot\dot{7}1428\dot{5}$. Write the decimals under one another in this order.

8. $\cdot13\dot{6} = \frac{123}{900}$. $\cdot\dot{8}\dot{2} = \frac{82}{99}$. Reduce these fractions to their least common denominator, obtaining $\frac{1353}{9900}$ and $\frac{8200}{9900}$. The required greatest divisor will have 9900 denominator, and the H.C.F. of 1353 and 8200 for numerator.

$$\therefore \text{ Ans.} = \frac{41}{9900} = {\cdot}00\dot{4}\dot{1}$$

9. $\cdot\dot{8}\dot{1} = \frac{81}{99} = \frac{9}{11}$. Hence, the rent of each floor is $\frac{11}{9}$ of the rent of the floor above. ∴ ground floor rent = $\frac{11}{9} \times \frac{11}{9} \times$ £51 6s. = £76 12s. 8d.

10. $\cdot\dot{3}8461\dot{5} = \frac{5}{13}$. Hence, $(1 - \frac{5}{13} - \frac{1}{4})$ of the original number is 57. Or 57 passengers = $\frac{19}{52}$ of the original number

$$\therefore \text{ Original number} = \frac{52}{19} \times 57 = 156.$$

EXAMPLES 13

1. £48487 5s. 4d.
2. £2357 3s. 11½d.
3. £23 14s. 6$\frac{6}{19}$d.
4. £537 9s. 9½d.
5. £99 3s. 8d.
6. £117 4s. 2$\frac{3}{16}$d.
7. £23 2s.
8. £427 9s. 10$\frac{4}{11}$d.
9. £52 7s. 6$\frac{3}{16}$d.
10. £8004 13s. 1½d.

GROOM, GARDENER & COOK

Work of the Groom, Stable Hands and Gardener. Qualifications and Duties of Cook and Kitchenmaid

Continued from Page 816

By A. EUNICE T. BIGGS

THE GROOM

The chief duty of a groom is to look after the horses, and to see they are in condition. His work in the stables will occupy most of his time, but in some households, where the total number of servants kept is not very large, he may be expected to perform certain indoor duties as well. He will probably be required to ride with his master or the ladies of the family. These, however, are purely subsidiary duties, his chief work being in connection with the horses under his care. When they are not working regularly they will need to be exercised each day, and a good groom will see that the exercise is suitable for each individual animal.

Feeding and Watering the Horses. These duties will fall to the share of the groom. He will have to supervise, and in many cases carry out, the feeding of the horses. Each horse will need three meals a day, the amount and character of the food varying with the work it is called upon to perform. The groom must be an early riser, for at 6 a.m. or earlier he will have to set about the preparation of the first meal. The food should, as a rule, be given before the horses drink. Care should be taken to procure pure water, which is improved by the addition of oatmeal. The water should not be too cold.

The groom should be on the alert to see that the shoes of his horses are in good condition. After shoeing, especial care should be given to the feet, and it is as well not to attempt much work immediately after a horse has been re-shod. Every day, after exercise, the horses' feet should be washed in water and then well dried with a brush. When the bit is removed it should be at once washed, dried, and polished. All the metal-work of the harness should be well polished, and the leather wiped over and cleaned. The harness should then be hung up in the harness-room on specially provided pegs. No harness should be left lying about, and the room ought to be well ventilated and free from damp.

THE STABLE HANDS

The cleaning of the stables is in the hands of the stablemen. Each day the stables should be thoroughly swept, and then washed, buckets of water and stiff brooms being necessary for the process. If this is in any way neglected the results are very disastrous to the freshness and neatness of the stable. Fresh straw should be placed under the horses directly it is needed.

The stable hands will assist with the care of the horses. The daily grooming takes some time; each horse has to be brushed over every part of the body, care being taken to follow the direction of the growth of the coat. If the horse is splashed with mud or stained, it may need special brushing with a brush dipped in water. Then the body is rubbed over with a cloth. Both mane and tail have to be well combed; they may also need trimming, and a little oil may be used to get a smooth, glossy effect.

Cleaning the Carriages. The carriage should be freed from mud before it hardens and dries. Plenty of water should be thrown over it, and a mop used to clean every crevice.

By means of a jack each wheel is in turn raised and left free to rotate. Then the wheels also are washed free from mud. The whole exterior must be thoroughly dried, and when it is quite dry it must be well polished with a leather. Sweet oil is used to remove stains, and also to preserve the varnish from cracks and blisters.

The brasswork, handles, etc., must be thoroughly polished with paste and leather. The carriage cushions should be taken out, beaten and brushed, and then replaced. The whole of the interior should be brushed and dusted, the foot-rug taken out and shaken, and the window-glass cleaned and polished. These duties may devolve on any of the men connected with the stables, from coachman downwards, but he is himself responsible for the work, and before taking the carriage out he should see that it is satisfactory in every way. If the springs get worn, the hinges of the door creak, or other minor repairs become necessary, he should be on the alert to detect these defects and see that they are remedied.

THE GARDENER

The gardener's duties will vary considerably, according to the area of the land for which he is responsible, and the number of under-gardeners and odd men whose services are at his disposal

In a large estate the head-gardener will probably be allotted a small house, which privilege is also enjoyed by the coachman. His duties will, to a large extent, consist of organising the work of the men under him. He will consult with the master as to the laying out of different parts of the garden, as to possible changes in its form and arrangement, and concerning the adornment of particular parts. He will be responsible for the supply of fruit and vegetables to the house. One of his privileges is a free supply of such food to his own table; he is also justified in receiving certain commissions from seed merchants, provided that he has always his master's interest at heart, and that he does not order from a particular firm merely to secure a large commission.

The head-gardener will have to see that the various products of the gardens, seeds, cuttings, etc., are properly collected and used to advantage. He will do little of the actual work himself, but he must be quick to detect which of his assistants excels in any particular kind of work, and allow him to do that work whenever possible. A man may be very deft in one direction and equally clumsy in another, and the head-gardener should see that each man's talents are made the most of in allotting the various tasks.

THE COOK

The cook is the chief of the servants who take their meals in the servants' hall. If she is working in a small establishment, many duties will fall to her share which in a larger house would have been relegated to other servants. Should she share the household duties with only one or two other servants, her own duties will include the care of various rooms besides her kitchens, and she may, by arrangement prior to her engagement, be called upon to assist with work outside her own particular domain.

It is of great importance that the cook should be an early riser. Unless many apparently trivial duties are performed before breakfast, the work after that meal tends to become disorganised and laborious. The cook should be up in good time, or she will find it none too easy a task to prepare the breakfast, and see that all is in readiness at the appointed hour. A punctual cook adds much to the comfort of the household. Her energy is a good example to her fellow-servants, and the various members of the family will be incited to more punctual habits if each meal is on the table at a fixed hour.

Characteristics of a Good Cook. A good cook will not only be careful to serve the meals at their proper time, but she will take great pains to ensure the food being well prepared and thoroughly cooked. She will not undertake the preparation of more elaborate dishes than she has the experience and skill to execute satisfactorily. She will do her utmost to serve every dish tastefully, and to prepare the food so that it is appetising and digestible.

A good cook is economical in her treatment of food. No scraps are wasted, and she will arrange that food is not allowed to get stale or turn sour. To secure this end it is important that she should examine her larder every day. Provisions that are put away for a second meal should be placed in clean dishes. Soups and liquid foods will probably need to be warmed up and replaced in clean tureens, and it is important that the interior of the bread-pan be frequently wiped out with a clean cloth.

The cook should daily go through her household supplies to see that no important article is missing. Unless this precaution is taken it is very likely that she will suddenly find herself at a loss for lack of mustard, or some other essential ingredient. Flavouring substances, spices, vinegar and similar articles should be added to the store-cupboard before the previous stock is quite exhausted.

The cook should keep a slate in some accessible corner of the kitchen, on which to record any deficiency directly she notice it. Then, when she receives her orders for the day, either from her mistress or from the housekeeper, she can refer to this in stating her wants. If she trusts entirely to her memory, she will probably find it fail her in some important particular.

The Cook's Dress. Neatness should be the keynote of a cook's attire. Her work necessitates long hours in the warm atmosphere of a kitchen, and she will find cotton or print dresses the most serviceable and durable.

The skirt, which should be short enough to clear the ground, should be covered with a large apron provided with a bib. Many cooks wear two aprons—a small neat one, and a larger one which practically covers the whole skirt. This upper apron protects the one underneath, and can be quickly removed should the cook need, say, to answer the door.

Comfortable, well-fitting shoes with fairly thick soles are essential, as constant standing is very trying to the feet.

Kitchen Arrangements. If the kitchen routine is to proceed without a hitch, the cook must be methodical and orderly in all she does. It is a great mistake to allow utensils to accumulate on the tables whilst cooking is in progress. As each basin, jug, or spoon is done with, it should be put aside to be washed later. Articles that have been taken from the store-cupboard, such as currants and flour, should be replaced as soon as they have been used. The cook only hinders her own operations by allowing the table to become strewn with utensils.

The daily duties of the cook will depend to a very large degree on the size of the family and the number of the servants. If but few of the latter are kept, the cook's duties will depend, to a certain extent, upon the arrangment made between herself and her mistress when she was engaged. She should be downstairs early, clean her kitchen range, light the fire, and put on the kettle. She should then proceed to the breakfast-room, which will probably be under her special care. This room will need careful sweeping, dusting, and rearranging. She should then lay the breakfast and put everything in readiness for the meal.

Duties. In some houses all this work in the dining and breakfast-room is done by the housemaid. In this case, after her preliminary kitchen duties, the cook can at once proceed to the hall and staircase. She should remove the mats, shake and replace them, brush the stair-carpet, rub up the rods, and dust each side of the "tread," and also the banisters. If the hall is tiled or covered with linoleum, it will need either washing or wiping over daily.

The cook will then return to her kitchen, sweep and dust it, and make it neat and comfortable before she sets about the preparation of breakfast. Sometimes the cook is responsible for the waiting at table during breakfast if the only other servant is a housemaid. In any case, she, as a rule, clears away after the meal. Whilst the family are at breakfast, the cook generally helps the housemaid to make the beds.

Having removed the breakfast things, the cook washes them up, with the exception of the plate and glass, which is left to the housemaid. Then she should tidy up her kitchen, and by 10 o'clock be in readiness for the visit of the mistress or the housekeeper.

The Preparation of Meals and Menus. The cook may sometimes be expected to suggest a menu for the day's lunch and dinner, or she may have to await instructions. If there are any deficiencies in the stores to be made up, she should then report them, at the same time drawing her mistress's attention to any particular food which should be consumed at once.

After the orders for the day have been received, the cook will find the morning occupied with culinary matters. Many orders will have to be given to the various tradespeople. The cook should see that her mistress is well served, that vegetables are sent fresh from the greengrocer, and that full measure is given.

During the morning the cook should prepare luncheon, and also make ready all that she can for the dinner. Cold sweets can be prepared, and the greater part of the preparation of many dishes may be arranged. When the actual time of dinner draws near, the cook should endeavour to so organise her work that there is no hurry or confusion at the last minute.

Among her further duties will be included the cleaning of the larder and of the scullery, if no scullerymaid is kept. The sinks should be flushed periodically with boiling water to which a little soda has been added. Greasy, soapy water has a tendency to clog the outlet pipes, as the water cools and the grease solidifies. This can be remedied by the use of very hot water every now and then. Certain other tasks, such as the washing and whitening of the front steps, may fall to her share in a small household, and she may, by arrangement, be asked to assist in doing a little laundry work.

THE KITCHENMAID

The kitchen, or scullery maid does the dirtier part of the kitchen work, leaving the cook more freedom to pursue her culinary duties. If both kitchen and scullery maid are kept, the actual cleaning and the washing of saucepans and other utensils falls to the lot of the latter. The kitchenmaid prepares the vegetables for table, and undertakes the less skilled cooking. She relieves the cook of most of her household duties, such as the scrubbing of steps and washing the hall, etc.

In a large establishment, working under a good cook, the kitchenmaid may acquire an excellent knowledge of cooking. This, however, will almost entirely depend upon her superior in the kitchen. Some cooks resent the idea of allowing their kitchenmaids to become proficent, and will banish them to other tasks in the scullery while the more interesting work is going on. The kitchenmaid will probably be entirely responsible for the preparation and serving of her fellow-servants' meals

Hints for the Scullerymaid. Plenty of boiling water should be used in washing up dirty kitchen utensils. The washing-up bowls should be washed out with strong soda-water after use, and then wiped dry. Dishes and plates should be rinsed in clean water after washing, and be put to dry in a specially constructed rack.

Much labour will be saved in the cleaning of baking-tins and saucepans if they are put to soak in hot soda-water as soon as they have been used, and all copper and tin utensils should be polished at least once a week.

No cooking utensils should be left dirty from one day to the next. After the saucepans have been cleaned, they should be carefully dried; pastry-boards and rollers should be scrubbed, and the kitchen table also kept scrupulously clean. The cleaning of the knives and the brushing of the gentlemen's boots will fall to the share of the scullerymaid. However, as is the case with each domestic servant, the exact duties of the kitchenmaid can hardly be defined. They vary in different households, and the requirements and individual wishes of each particular cook determine whether the position of kitchenmaid is altogether desirable and pleasant.

THE HOUSEMAID

The housemaid should possess a love of order and of punctuality. She should be neat and methodical in her work, an early riser, and if she is skilful with her needle she will be able to add much to her mistress's comfort. In a large establishment the duties of the housemaids will vary with the number kept and also with the number of other servants included in the household. The upper-housemaid will have only very light duties to perform, but her responsibilities will be fairly heavy, for she will have to superintend the work of the other housemaids, and see that every detail of it is carried out thoroughly.

The drawing-room will be under her particular care. She may undertake its sole charge, doing all the sweeping and dusting herself; or she may prepare the room for sweeping, and after this has been done by an under-housemaid, she herself may dust and polish.

The Duties of the Housemaid. Where several housemaids are kept, the various duties will be divided among them, but the daily tasks of each will be, to a great extent, similar. Certain rooms will be entrusted to the housemaid, which she will have to arrange before breakfast. She will have to open the shutters and windows to air the rooms, tidy the hearths and lay the fires, sweep the carpets and rugs, and then very carefully dust the whole room. When the housemaid is down in good time she will be able to do all this work before beginning her duties upstairs. If there is no lady's-maid, she must, at the appointed hour, call the members of the family, taking hot water to each room. If the mistress takes a cup of early tea, the housemaid must take this up also. She will then come down to her own breakfast, and when that is finished she will set the breakfast of the household in readiness. In the case of this work being undertaken by the cook, the housemaid will find plenty to occupy her until the family are assembled for breakfast. During that meal she will repair to the bed-rooms and strip the beds for airing. Her next duty is to empty the baths, arrange the washstands, and put fresh water in the water-bottles and jugs.

Bedmaking. The process of bedmaking is next begun. Each bed, after a good airing, is made to suit the individual taste of its occupant. The housemaid will probably be given some assistance in bedmaking, either by the cook in a small household, or by another housemaid in a larger establishment. The sheets should be arranged smoothly and well tucked in, the pillows and bolsters beaten up and shaken so that they are soft and comfortable. Some mattresses will need to be turned and shaken daily, and in the case of a feather bed this is absolutely essential.

When the beds have been made, the bed-rooms will need to be cleaned. The carpets should be gone over with a dustpan and brush and the skirtings dusted. The dusting process should be applied to every article of furniture in turn, and every crevice should be free from dust. The furniture should be carefully polished, also the dressing-table, mirror, and silver.

The bed-rooms should be periodically turned out, a regular routine being observed in carrying out the work. After the bed and most of the furniture have been covered up with dusting sheets, the bed-room carpet is thoroughly swept. It is well to remove from the room all small and portable articles of furniture—vases, dressing-table ornaments, etc., and to loop up the window-curtains. It is a good plan to scatter some tea-leaves or some salt over the carpet before sweeping, to freshen it up.

All polished furniture must be well polished by friction with a leather or silk cloth and by the occasional use of a prepared polish.

Occasional Duties. In a small establishment the housemaid will be responsible for the plate and glass used at table. Once a week she will have thoroughly to polish all the silver, using a good powder for the purpose. In such households the housemaid will lay every meal, wait at table, bring in the afternoon tea, answer the front-door bell, and show in visitors. When, in the spring, the house is subjected to a thorough cleaning, she will be responsible for much of the work to be done.

The lamps and globes used in lighting the house will be under the housemaid's care. If the cleaning of them also falls to her lot, she must be very careful over it. Special brushes, scissors, and cloths should be kept for oil lamps, and the trimming should be performed every day, for lamps never burn well without very careful attention.

Care of the Sitting-rooms. The housemaid will be responsible for the care of the dining-room and the drawing-room. Each room must be carefully freed from dust and dirt daily. A dustpan and brush should be used for the carpet, and every article of furniture must be well dusted and polished. In small households, where there are many grown-up daughters and few servants, the care of the drawing-room ornaments is often undertaken by a member of the family. This frees the housemaid and enables her to get on with other more important duties. Before the midday meal the housemaid should retire to her room and dress herself neatly for duty during the rest of the day. In the morning she will wear a light-coloured print dress and a large apron; in the afternoon these are discarded for a black dress and rather more ornamental muslin aprons. The housemaid's cap should be simple, and her collars and cuffs quite irreproachable in their whiteness.

Evening Work in the Bed-rooms. The housemaid is responsible for opening the bed-room windows at suitable times, and closing them again at sunset, or a little later. When it becomes dark, she must visit each bed-room, draw down the blinds and close the curtains. The bedspreads and pillow shams should be removed, and the bedclothes turned down and the night garments neatly arranged ready for use. Then the bed-room fires should be lighted, if the weather is cold, in time to make the room comfortably warm by bed-time. A can of hot water should be put in readiness in every room. These preparations can be made about an hour and a half before the time of dressing for dinner in a large establishment. Then, when the family are assembled at the meal, the housemaid will return to the bed-rooms, re-arrange the washstand, and set the room in order for the night. Candles should be placed in readiness, the candlesticks having been cleaned during the morning.

An energetic housemaid will get through her work in good time, and have leisure to sew for her mistress if required to do so. She should, therefore, be clever with her needle. Much household mending, remaking, and patching may fall to her share, and if she can do such work efficiently she will add greatly to her mistress's comfort.

THE PARLOURMAID

A parlourmaid's duties are practically those which would be performed by a single man-servant. She is usually kept in those households where no lady's-maid is found, in order that she may perform little services for her mistress. An extra maidservant, such as a parlourmaid, can add greatly to the comfort of the household without much extra trouble. In houses where a cook, a housemaid, and a young maid who assists both cook and housemaid are found, the parlourmaid is often the fourth servant engaged.

The Parlourmaid's Dress. The parlourmaid has only light duties to perform, and she will therefore be expected to be always neat and trim. She should wear a light print morning dress, with a muslin apron, and a black dress covered by a more elaborate apron in the afternoon. Her cap, cuffs, and collars should be invariably neat and clean. It is the duty of the parlourmaid to wait at table and arrange the meal beforehand. If she is assisted by the housemaid at table, she takes precedence of her. If she assists a manservant, she assists him as if he were a butler and she a footman.

Daily Routine. The daily routine of the parlourmaid closely resembles that of a single manservant, except that she will probably be called upon to assist in more purely domestic duties from which he would be exempt. She will wait more particularly on her mistress, and she may be called on to assist the housemaid in bed-room work, such as bedmaking, etc.

The parlourmaid will be responsible for the plate and glass used at table if no manservant is kept; and these she will have to wash and polish after use. Her time will be well filled in performing these duties, in laying the table for the various meals, in waiting at table, and in clearing away when the meal is over.

The parlourmaid is generally required to answer the dining-room and drawing-room bells, to open the front door, and to announce visitors. She will also bring in afternoon tea and serve the coffee after dinner. She will be responsible for the various sitting-room fires, and for the ventilation of breakfast and dining-room after meals.

THE HOUSE-PARLOURMAID

In small establishments, where but few servants are retained, one maid is engaged to perform the joint services of parlourmaid and housemaid. Such a maidservant lays the table for meals, waits at table, clears away afterwards, and washes the plate and glass. She also has charge of the bed-rooms, calling the different members of the family, and carrying up hot water. After breakfast, she makes the beds, generally with assistance, and dusts and arranges each room in turn. In the afternoon she answers the front-door bell, and brings in tea, etc. In the evening she sets the table for the last meal, waits during its progress, clears away afterwards, and then prepares the different bedrooms for the night. Thus the house-parlourmaid performs the most important duties of both housemaid and parlourmaid.

THE BETWEEN-GIRL

The between-girl is generally a young maidservant who spends part of her time in the kitchen assisting the cook, and part in the bed-rooms, etc., helping the housemaid. As the cook's assistant, she does much of her work that ordinarily would be undertaken by the kitchenmaid. She helps in the washing up of pots, pans, and dishes. The polishing of tins and copper utensils will fall to her lot, and she will probably prepare vegetables for cooking. She will peel or scrape the potatoes, and cut up and put the cabbages to soak in salt water, etc. The between-girl may also be called upon to clean boots and knives. Her work in assisting the housemaid will be to help to make the beds, and perhaps to arrange the washstands, dust the skirtings of the rooms, etc.

THE STILL-ROOM MAID

The still-room maid is now but seldom found in households. Her duties are simple, but as still-room maid a bright and capable young girl will find she has abundant opportunities of learning many useful details of household management. Generally, she is regarded as the housekeeper's assistant. When the housekeeper is busy making preserves of various kinds, the still-room maid will be kept busy picking the fruit, etc., used. She will occupy herself stoning fruit in less busy times.

The still-room maid is responsible for the arrangement of the housekeeper's room; she will light the fire there, sweep and dust the room, and lay the various meals. When the meals are prepared, she carries them in to the housekeeper's room, and waits at table on the upper servants, who take their meals there. In some households she arranges the flowers for the various rooms, and prepares the dishes of sweetmeats and dessert for the dining-room.

THE LAUNDRYMAID

The services of a laundry-maid are seldom requisitioned, except in large houses in the country. The difficulty of conducting laundry work satisfactorily in a large town is sufficient reason for the work to be sent to the professional laundress, who will doubtless arrange to carry on her work on the outskirts of the town.

The laundrymaid generally performs her duties in a separate part of the house, either quite detached from the main building or else only communicating with it by a yard or passage. The building will comprise a wash-house, a room for ironing purposes, with properly constructed stoves, and probably presses or cupboards in which the various articles may be thoroughly dried.

Importance of her Work. The laundrymaid has a very important task, and much of the comfort of every member of the family depends on the excellence of her work. She must carefully avoid the use of all chemicals and bleaches, which so quickly rob and spoil fine underwear. She must also be a skilful ironer. The details of her work will be given under the section LAUNDRY WORK.

When the soiled clothes and house linen are given to her, she should carefully count and sort it. Stains and marks should be removed and the different classes of material sorted, in order that they may be subjected to the correct treatment. Some of the clothes will need careful soaking, and this may be done the day before the actual washing process begins.

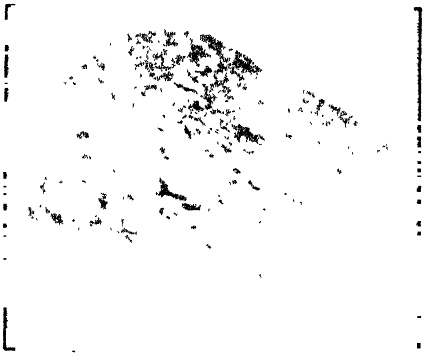
THE OLDEST, OR IGNEOUS ROCKS

How they Cooled and Crystallised into their present formation. The Ten Families of Igneous Rocks and their Characteristics

By W. E. GARRETT FISHER

WE have seen that the *igneous* rocks must be the oldest of all, and as it is always well to follow the order of Nature, we shall begin by giving an account of the most important constituents of the earth's crust which belong to this class. Then we shall describe the *sedimentary* rocks, which have been derived from the igneous by the work of natural agents, by weathering, attrition, and deposition. Lastly, we shall glance at the *metamorphic* rocks, which share the characteristics of both these main classes.

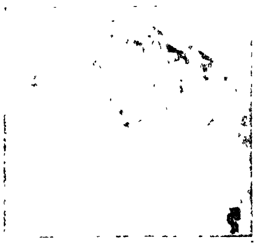
The Igneous Rocks. The *igneous* rocks, as their name implies—from the Latin *ignis*, fire—have come into existence through the action of heat. The older geologists divided them into two great groups, according to the circumstances in which they were prepared in the vast laboratory of Nature. Looking back at the history of the earth, as described in an earlier chapter, we see that the whole substance of which the earth's crust is now composed was once in a state of fusion. Thus every rock which we can find on the surface of the earth must once have formed part of an igneous mass; in other words, it was once liquid, like the lava which pours from the vent of an active volcano or the slag of a blast-furnace which is skimmed off the molten iron. But it would be vain to hope to find any part of the earth's surface still in the condition in which it was left when the molten rocks first solidified. The natural agents of change, which we shall study in a later chapter—wind and rain, ice and running water, and all the powers of the air—have been at work for countless ages to modify those primitive conditions.



23. PUMICE

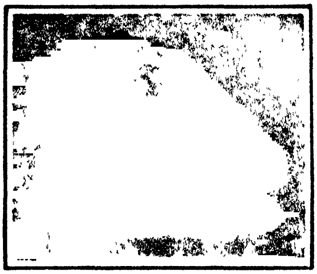
Volcanic and Plutonic Rocks. It is clear, however, that the igneous rocks which we now recognise have had their origin in two ways. They may have been solidified deep down beneath the surface of the earth, and have gradually made their appearance at the level of the ground, where we can now study them, by the double action of those forces which gradually upraise the lower strata in one part of the earth, while they depress the upper portions of the crust in another; or they may have been exposed to view by the slow denudation which is caused by the action of the weathering agents, which also break these rocks down into sedimentary forms, and which are capable—given sufficient time—of removing strata thousands of feet in thickness, so that the giant masses of the Alps are but the trifling remains of the inconceivable mountains which once reared their summits into prehistoric sky. Again, the igneous rocks which we now find on the earth's surface may have been brought to the ground-level in a liquid form by what we call volcanic forces, as is even now happening at Vesuvius, Krakatoa, Mont Pelée, or the other active volcanoes which survive from the remote age when they were far more active and more numerous. Igneous rocks which were produced in the latter fashion are called *volcanic*, whilst those which solidified deep down, and have since been revealed, are called *plutonic*. These names are derived from those of two Greek deities—Vulcan, who was supposed to work inside the burning mountain of Etna at forging the bolts of Jove, and Pluto, who was the ruler of the under-world.

Physical Distinctions. These two divisions correspond to well-marked physical distinctions in the two classes of rocks. The volcanic rocks, which mainly cooled on or near the surface, naturally solidified far more quickly, and are therefore marked by a much finer crystalline structure [see PHYSICS]. Sometimes—as in obsidian, or the so-called volcanic glass—they show no crystalline structure at all. Often they are full of holes, or vesicles, left by the escape of the gases with which they were charged when they first escaped from the vent of the volcano. Pumice-stone [23], in which the holes are more extensive than the substance, is a familiar instance. In general, they closely resemble the slag which the student can examine on the refuse heaps of a blast-furnace. Volcanic products may be *superficial*, poured out in vast sheets on the surface, or *intrusive*, thrust up in *dykes* or *bosses* from the hot interior. The plutonic rocks, however, solidified deep down under the earth, and consequently cooled so slowly that they had time to develop a well-marked and frequently coarse crystalline structure. The immense pressure of the superincumbent rock-masses—often 10 or 12 miles thick—compacted these rocks as they cooled, and gave them a close texture which left no room for the vesicles, or bubbles, so characteristic of the volcanic rocks. There are other distinctions, but these two are sufficient for the beginner to note. Volcanic rocks show small crystals, or none at all, and are often loose in texture or full of holes. Plutonic rocks are close in texture, and show large crystals. For the purposes of elementary descriptive geology, however, this distinction, though it must be clearly understood, need not be used in classifying the igneous rocks. The same rock is found in both conditions, according to the circumstances in which it was produced.



24. GRANITE, WITH CRYSTAL OF FELSPAR

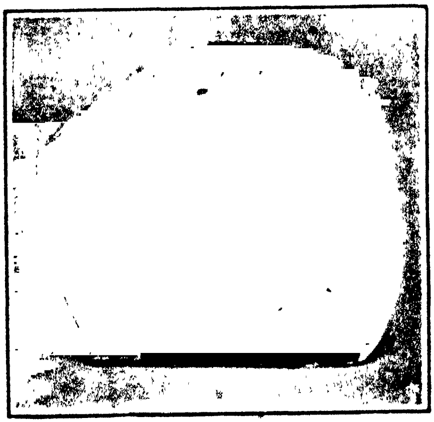
Crystallisation of Rocks. Once upon a time all the igneous rocks existed in the form of a liquid lava. This liquid was closely akin to ordinary molten window-glass, which consists, like it, of a mixture of silicates. Of course, it must not be thought of as transparent, because it contained a great many impurities and colouring matters from which the glass of our manufacture is carefully purified or kept free; but in all essentials it was glass, and sometimes cooled, as in the case of obsidian, into a substance hardly to be distinguished from the coarse glass which is made for bottles. If it was allowed to cool slowly, however, its components arranged themselves into crystals of the fundamental forms corresponding to their chemical composition, and the slower the cooling the more complete was this process of crystallisation. Sometimes it was cut short in the middle. Part of the liquid had crystallised when the remaining *magma*—as it is technically called—was solidified so fast that it had not time to form crystals. Consequently, we find igneous rocks which may be wholly crystalline, like some granites, or partly crystalline, with the crystals set in a formless *matrix*, like porphyry, or not crystalline at all, like obsidian.



25. GRANITE

Again, the igneous rocks differ widely in their chemical composition, though they are all composed—with insignificant exceptions—of the minerals which have already been described. It is true, by the way, that the exceptions are insignificant from a geological point of view; but, humanly speaking, we must treat them with respect, as they include some of the ores from which our currency and much of our manufactures are derived.

Classification of Igneous Rocks. There is as yet no thoroughly satisfactory *classification* of the igneous rocks. There are several more or less efficient systems by which such a classification may be attempted. It is quite unnecessary to trouble the learner with an account of these. One need only say that rocks may be sorted into groups in different ways, according as we consider their chemical composition, their texture, the minerals of which they are built up, their mode of occurrence in the field, their origin, or their distribution in time (geological age) or space (locality). Various attempts have been made to discover a really scientific principle of classification, but as yet they have not been wholly successful. It depends on the object of study whether one or another of the various methods proves to be the most convenient. For our purpose, the learner may be recommended to the classification adopted by Sir Archibald Geikie in his "Text Book of Geology," Book II., Part 2, Sect. vii., where it may be studied at length by those who desire a closer acquaintance with the leading igneous rocks than we can give in these necessarily brief pages. It will be understood that the student must supplement this part of the course by an examination of the various rocks, both in a museum and in the field, and, if possible, by some work in a petrological laboratory, and in a field class. It is sufficient here to give an abstract of Sir A. Geikie's classification, which is based on the chemical and mineralogical composition of the igneous rocks, and arranges them in a progressive order, according to the proportion of silica which they contain, from the most acid to the most basic.



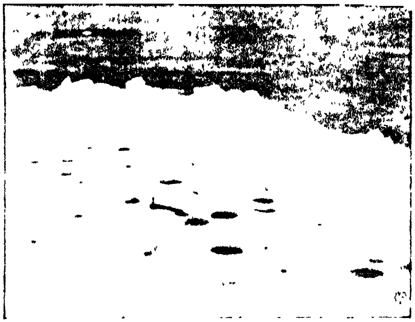
26. MICA (MUSCOVITE)
From Madras

[See the course on CHEMISTRY for explanation of these terms.] There are ten families of the igneous rocks, which Sir Archibald Geikie divides as follows.

Granite Family. This is by far the most important family of igneous rocks. The granites and their allies compose a very large proportion of the earth's crust, and everybody is familiar with the vast rock-masses and imposing cliffs of granite which play so large a part in the harmonies of the terrestrial landscape and in the operations of human architecture. They are chiefly plutonic in origin.

GRANITE consists typically of the three minerals, quartz, felspar, and mica, which form a thoroughly crystalline aggregate. There are very numerous kinds of granite, which vary (*a*) in the size of the crystals, sometimes so coarse as to be several inches in diameter, sometimes so fine that the naked eye cannot distinguish the crystals of the various minerals from one another; (*b*) in the chemical composition of the felspar and mica [see section on MINERALS]; (*c*) in the presence of other minerals in addition to the quartz and felspar which are essential to the constitution of a granite. For a more detailed account of these varieties the student must refer to Geikie—or to Teall's "British Petrography." He will be well advised also to study all the specimens of granite in any accessible geological museum, from which he will learn how a single rock may present itself in innumerable and exceedingly varied forms, which, nevertheless, can all be referred to a single family. They are the most acid—contain the most silica—of igneous rocks. [**24-26**]

GRANITE-PORPHYRY is a fine-grained granitoid rock, which consists of a very fine crystalline matrix of quartz and felspar, looking almost homogeneous to the eye, through which are scattered large crystals of felspar.



27. GIANT'S CAUSEWAY
Showing basaltic columns

QUARTZ-PORPHYRY is a rock consisting of a close-grained matrix (grey, brown, or pink) of quartz and felspar, through which are disposed distinct crystals of quartz. These porphyries—a term reserved for rocks consisting of finely crystalline and apparently homogeneous ground-masses, through which larger crystals are scattered—supply some of the most ornamental of our building stones. They are often confused in popular language with the marbles.

Rhyolite Family. The *rhyolites* are mainly of volcanic origin. Their name signifies this, being derived from the Greek word "to flow." They are distinguished from one another by variations in texture, depending on the conditions in which they cooled from the great lava outbursts of the early world.

RHYOLITE is a typically acid lava, with a high percentage of silica (77 or more). It varies much in structure and texture. Some variations consist of a crystalline aggregate of quartz and felspar which might be mistaken for granite; but the more common form is that of a finely crystalline ground-mass of quartz and felspar, in which occasional larger crystals of these minerals are scattered.

OBSIDIAN, or volcanic glass, is a glassy form of rhyolite which strongly resembles bottle-glass, and, like it, breaks with a conchoidal fracture. It is usually black, brown, or green. About 75 per cent. of its composition is silica, with about 13 per cent. of alumina and traces of other oxides. Its glassy structure is due to its having solidified so rapidly that there was no time for crystals to form.

PUMICE is a rhyolite which has cooled whilst so full of escaping gases that it has developed a spongy, cellular texture, like petrified froth. It is a characteristic volcanic product.

FELSITE is a rhyolite which was originally glassy, but has been devitrified by the process of time until it has developed a characteristic structure, which often causes it to be confused with conglomerate.

PITCHSTONE represents a still further stage of devitrification, and has a resinous or pitch-like lustre, whence its name. It is a volcanic glass, containing tiny crystals of quartz, felspar, hornblende, etc.

Syenite Family. *Syenite*, the rock of Syene, is a holocrystalline mixture of felspar and hornblende, with which mica, augite, magnetite, and quartz are sometimes associated. A typical syenite is a coarse-grained mixture of flesh-coloured orthoclase felspar and black hornblende. There are many varieties of syenite, which are chiefly found as volcanic or intrusive sheets and dykes. Though less abundant than the granites, they play an important part in the formation of rock-masses.

Elaeolite-Syenite Family. These are also intrusive rocks of volcanic origin, which are characterised by the association of the variety of nepheline known as elaeolite with orthoclase felspar. No quartz is to be found in them, since they do not contain enough silica to crystallise out in this form.

Diorite Family. These rocks possess a granitic structure, but contain less silica and seldom any free quartz, whilst they differ from the syenites in containing felspar as plagioclase instead of orthoclase—soda-lime felspar instead of potash felspar. From their typical colour they were formerly known as "greenstones"—a term which has no scientific foundation, though it is still often used for convenience in a hasty classification of rocks in the field.

DIORITE is a holocrystalline mixture of plagioclase and hornblende, with traces of other minerals, such as mica and magnetite. It contains about 60 per cent. of silica.

Trachyte Family. The *trachytes* are volcanic rocks whose name signifies that they present a roughness to the finger. Their essential constituent is sanidine, a glassy variety of orthoclase felspar. *Trachyte* is a lava of tertiary and post-tertiary times, which is found in most of the old volcanic regions of Europe. Special varieties are *phonolite*, or *clinkstone*, which gives out a characteristic ringing sound when it is struck with a hammer, and *trachyte glass*, a variety of volcanic glass which is less acid than obsidian.

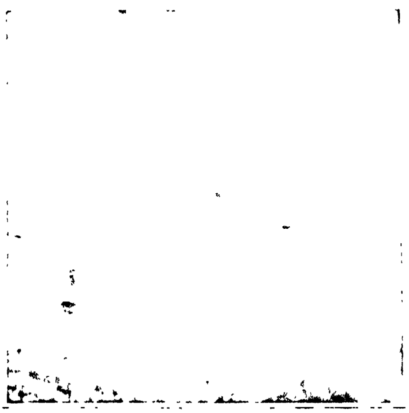
Andesite Family. *Andesites*—originally found in the Andes—are more basic than the trachytes, from which they are also distinguished by having plagioclase as their felspar. They usually have a compact ground-mass, in which prisms of felspar are scattered. They contain about 60 per cent. of silica.

Gabbro, Dolerite, and Basalt Family. This is an interesting series of igneous rocks, characterised by their small percentage of silica. "At the one extreme come rocks with a holocrystalline structure like the gabbros, passing into others of a hemicrystalline character (dolerites) where, amid abundant crystals, crystallites, and microlites, there are still traces of the original glass, and then graduating into types where the texture is still closer, with more abundant ground-mass and often a more basic composition (basalts), until at the other end come true basic volcanic glasses, which externally might be mistaken for the pitchstones and obsidians of the acid rocks. The more coarsely crystalline (holocrystalline) varieties are almost always intrusive in bosses, sills, or dykes. Those of closer texture are often found as superficial lavas as well as in intrusive forms" (Geikie). After the granites, this is probably the most important and numerous group of igneous rocks. We can only find space for a few notes on the leading types.

GABBRO is a coarsely crystalline rock composed of plagioclase (soda-lime felspar), with pyroxene, olivine, and magnetite. The silica is about 50 per cent. The structure is usually similar to that of granite or granitoid.

DOLERITE is usually holocrystalline, and consists of plagioclase, with a ferro-magnesian mineral (augite or olivine) and magnetite. Silica about 50 per cent.

BASALT is a black, very compact, apparently homogeneous rock, with a conchoidal or glassy fracture, in which the constituent minerals can only be observed with the microscope, which reveals a minute crystalline structure. Basalts consist of plagioclase, pyroxene, olivine, and magnetite, and contain from 33 to 50 per cent. of silica. The basalts, of which there are numerous varieties, are typical products of volcanic activity. Some occur as the remains of superficial outbursts, but more commonly they are intrusive, and appear in great dykes and bosses which have been thrust up to the surface of the earth from the heated regions of the inferior crust. Basalt often passes into the condition of volcanic glass when it has cooled very quickly. [27, 28]



28. BASALTIC COLUMNS
Showing sides of prisms and jointing

Limburgite Family. These are volcanic rocks of highly basic composition, in which felspar is wholly absent. *Limburgite* is a fine-grained to vitreous rock, composed of augite, olivine, magnetite, and apatite. Silica about 42 per cent. *Augite* consists of augite and magnetite in a glassy matrix.

Peridotite Family. These rocks are the most basic and contain the least silica, averaging about 40 per cent., of all igneous rocks. Their chief constituent is olivine, with augite, hornblende or mica, and magnetite. They are holocrystalline when fresh, but are usually found in altered states. They are mainly intrusive forms of volcanic rocks.

SERPENTINE, as a rock, is a massive form of the mineral serpentine, which is a product of the alteration of peridotites containing olivine. It is a compact or finely granular rock of a characteristic dirty green colour, streaked with brown or red, like the scales of a serpent, whence its name. It is a hydrous magnesian silicate, which is formed by the action of superficial agents from the olivine originally intruded by volcanic action.

A Lesson on the Ring or Wheel. Circles Touching Lines and Circles. Foiled Figures of Semicircular and Tangential Arcs

By WILLIAM R. COPE

The Ring. Our model for this lesson is the ring, which well illustrates two important principles to be observed—*viz.*:

1. That although the rim of an object, such as that of a cup, vase, wheel, etc., may be the same thickness all round, yet it will not necessarily appear so.

2. How the wheels of vehicles, machinery, etc., should be drawn, as regards not merely the apparently varying thickness, but the apparent *direction* of their major axes.

Horizontal Positions of the Ring. Figures 241 and 242 indicate how the construction should be made when the ring is lying in a horizontal plane. The first difficulty is with regard to the *direction* of the major axis, and when determining this the student should not be misled by the apparent direction of the edges of surrounding objects, such as the edges of, say, a board, box, table, etc. *Whatever the apparent direction of the latter may be, the major axis of the ring or wheel will always appear horizontal when the ring is lying in a horizontal plane.* This should be verified by the student by placing the ring on a flat table or board, so that the edges of the latter are receding from him in various directions, as in 247 and 248. Therefore, commence the construction by drawing a horizontal line AB for the major axis of the top outer ellipse, carefully observing how high or how low it should be with regard to neighbouring objects.

When the length of AB has been fixed, bisect the axis in the point C, and through C draw the minor axis DE at right angles to AB. Then find out the apparent length of this minor axis compared with AB, and through the four points A, B, D, and E draw the curve of the ellipse, which represents the outer top edge of the ring. Now we come to the most important principle to be observed concerning this and similar objects, and that is, *although the top inner edge is really parallel with the outer edge, it does not appear so.* By careful observation of the model it will be seen that the ring *appears considerably wider at AF and JB towards the ends of the major axis* than it does at EG and DH, the ends of the minor axis. The student should now make further experiments with cups, vases, jars, etc., and he will find that there is generally an apparently wider thickness at the ends of the major axis than at the ends of the minor axis. More illustrations bearing on this point will be given later when dealing with vases of various shapes. Thus it will be seen how important it is to determine the apparent thickness at AF, JB, EG, and HD very accurately. It should be noted that the major axis of the inner ellipse does not quite coincide with that of the outer ellipse, but is very slightly above. The further top thickness, DH, is also apparently slightly less than the nearer top thickness EG. Then draw the inner ellipse through the four points E, G, J, and H. Now find out the apparent upright thickness EK, which is *practically about the same* as AF or JB but *theoretically a little larger*, because EK is slightly nearer than AF or JB, but the difference is scarcely appreciable, unless the ring is very large. The lower outside edge, it must be remembered, is part of another ellipse vertically under the top outer one, which was drawn first. In 241 and 242 the construction shows the invisible portion by dotted lines. There is yet another curve, the lower and inner edge, which is but little seen in 241, but better in 242. This curve is also part of an ellipse, as shown in 241 and 242, which will explain better than words what the curve appears like, and its relation with the upper and inner ellipse.

Oblique Positions of the Ring. Figures 243 and 245 are representations of the ring in a leaning or slanting position. When beginners attempt to draw such views they generally make a very bad mistake about the *direction* of the major axis AB, because they do not use their eyes properly, and do not know the very good guide, that if the pencil is held so that it apparently passes through the two points C and D—the apparent intersections of the upper and lower inner edges—the major axis appears to be in *the same direction*, but not exactly in the same *position*, for the major axis is practically midway between the point E on the further side, and F on the nearer part of the outer edge. *The above guide holds good when the ring is in any position whatever* [see 241 to 245]. After the direction, position, and length of the major axis are determined, the construction is the same in method as in 241 and 242. The student should remember and *see* that the major and minor axes are always at right angles to each other.

Vertical Position of the Ring. Figure 244 is an interesting and important view, supposing the ring to be below the eye-level, and standing in a *vertical* plane, as the wheels of a cart or carriage might be. Here, again, beginners make errors, because they think the major axis must be upright since the ring is upright, *but it is not necessarily so*; in fact, the axis can only appear *vertical* when the centre of the ring is exactly on a level with the eye. The above statement should be compared with what was explained about the cylinder in the position shown in 148, and the student will find that the law is really the same, for the ring may be considered as a hollow cylinder with its

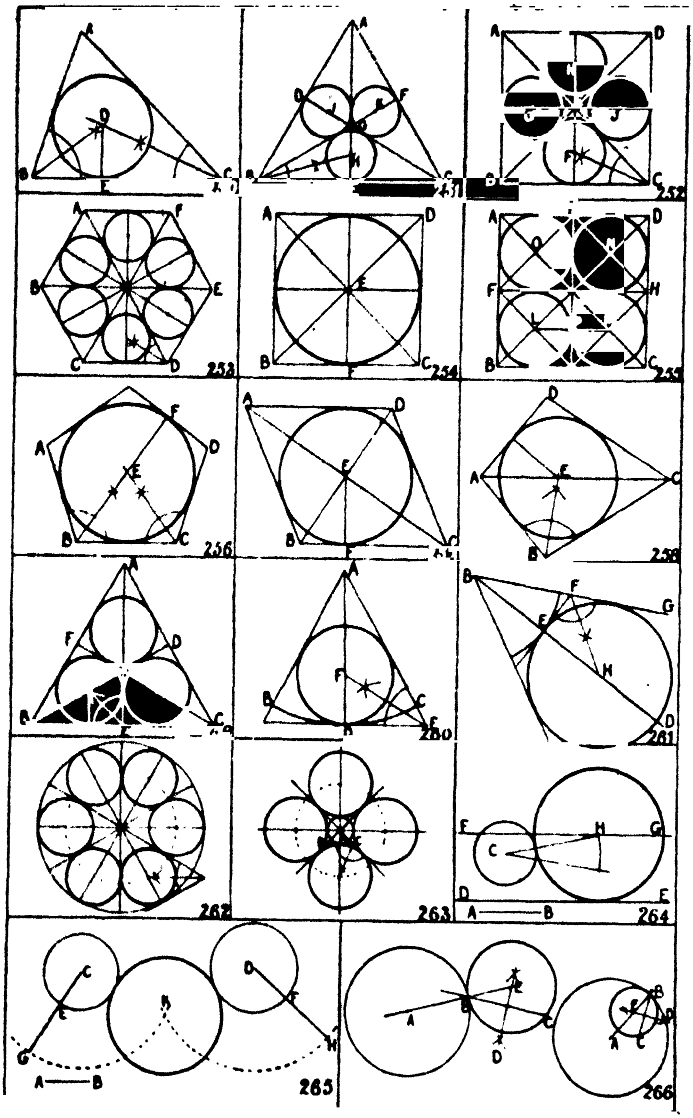
A LESSON ON THE RING AND OBJECTS SIMILAR IN CONSTRUCTION



CIRCLES TOUCHING LINES AND CIRCLES

axis receding to the right in 244 in the direction *DC*; therefore, the major axis *AB* must be drawn at right angles to *DC*—the axis of the object.

Application of Above Principles. See how the foregoing principle is applied in the drawing of the clock in 246, where an imaginary line through I. and VII. for the major axis of the dial is at right angles to *AB*, the axis of the clock, although the face is really in a vertical plane. The clock is assumed to be above the eye-level.

Again, in 249 the major axes of the two wheels are both at right angles to the axle of the cart. Thus, the longest direction of the wheels is apparently slanting, and yet the wheels are upright in reality. Further attention should be given to the width of the rim of the front of the clock in 246; the hat brim in 247; the rim of the plate in 248; and the widths *AB* and *CD* (at the ends of the major axes) of the rim of the wheels in 249, which are wider than *EF* and *GH* at the ends of the minor axes.

Rules and the Perceptive Faculties. It is necessary that students should not merely draw by rule, but they should endeavour to so train their perceptive faculties that, after a time, they may be able to see intuitively, nay, almost without effort, the varying changes in the appearance of an object. Rules, if correctly remembered, will give much guidance with regard to *how to see*. There are, unfortunately, many students who retain only a vague notion, or even, perhaps, a distortion or transformation, of some rule which has been explained to them, and then, of course, the rules are worse than useless. Therefore, try to remember rules correctly, and, as well, do all you can, by practising drawing, to improve the hand in skill and the eye in seeing aright.

PRACTICAL GEOMETRY

Circles Touching Lines and Circles.

The problems in this part depend for their solution upon the following truths in Euclid:

i. If a straight line be a tangent to a circle, and from the point of contact a line be drawn perpendicular to the tangent, the centre of the circle shall be in that line (Euc. III. 19).

ii. If one circle touch another internally in any point, the straight line which joins their centres being produced shall pass through the point of contact (Euc. III. 11).

iii. If two circles touch each other externally in any point, the straight line which joins their centres shall pass through that point of contact (Euc. III. 12).

250. To Inscribe a Circle in a Given Triangle *ABC*. Bisect any two angles *ABC* and *BCA* by lines intersecting at *D*. From *D* draw *DE* perpendicular to either of the sides of the triangle, then *DE* is the radius and *D* the centre of the required circle.

251. IN A GIVEN EQUILATERAL TRIANGLE *ABC*, TO INSCRIBE THREE EQUAL CIRCLES, EACH TO TOUCH ONE SIDE AND TWO CIRCLES. Bisect the angles by lines which also bisect the sides in *D*, *E*, and *F*, and intersect at *G*. Inscribe a circle in the triangle *GBC* (Prob. 217). Mark off *GJ* and *GK*, each equal to *GH*, then *J* and *K* are the centres of the other circles.

252. IN A GIVEN SQUARE *ABCD*, TO INSCRIBE FOUR EQUAL CIRCLES, EACH TO TOUCH ONE SIDE AND TWO CIRCLES. Draw the diagonals and the diameters intersecting at *E*. Inscribe a circle in the triangle *EBC* (Prob. 217). With centre *E* and radius *EF* mark off *EG*, *EH*, *EJ*, each equal to *EF*, then *G*, *H*, and *J* are the centres of the other circles.

253. IN ANY GIVEN REGULAR POLYGON (SAY *ABCDEF*), TO INSCRIBE AS MANY EQUAL CIRCLES AS THE FIGURE HAS SIDES, EACH CIRCLE TOUCHING ONE SIDE AND TWO CIRCLES. Divide the figure into equal triangles and inscribe a circle in each, as shown.

254. TO INSCRIBE A CIRCLE IN A GIVEN SQUARE *ABCD*. Draw the diagonals and diameters to find the centre *E*, and with radius *EF* describe the circle.

255. WITHIN A GIVEN SQUARE *ABCD*, TO INSCRIBE FOUR EQUAL CIRCLES, EACH TOUCHING TWO SIDES AND TWO CIRCLES. Draw diagonals and diameters as before. Join *F*, *G*, *H*, and *K*. The intersections *L*, *M*, *N*, *O*, with the diagonals, are the centres of the circles. Join *L* and *M*, then *LP* or *MP* is the radius required.

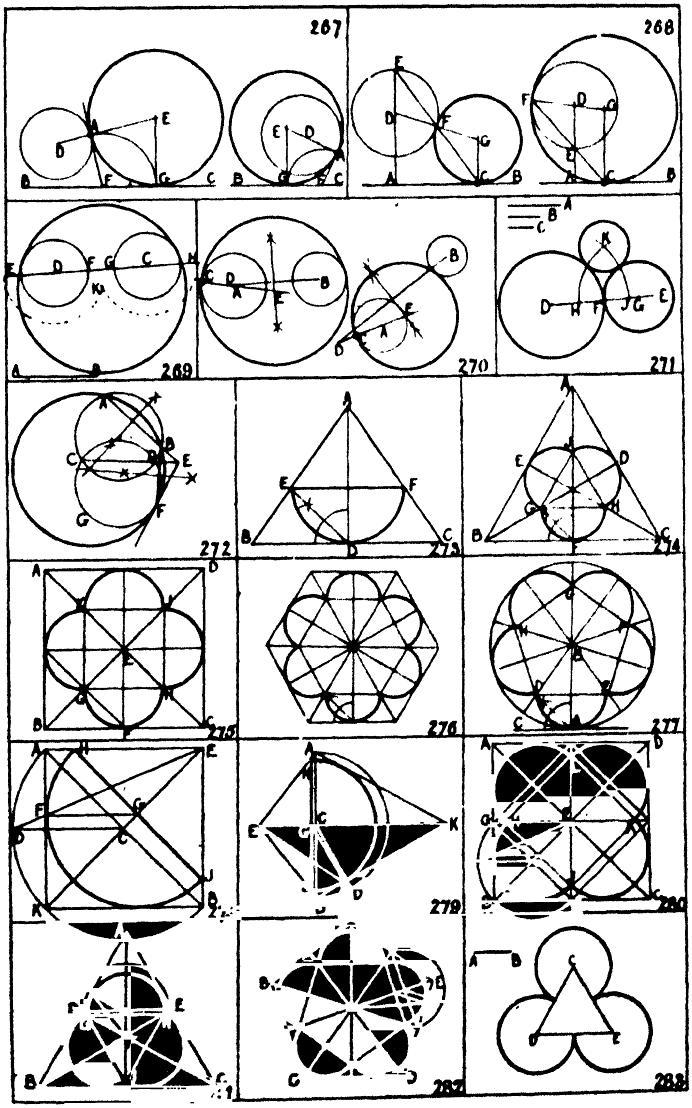
256. TO INSCRIBE A CIRCLE IN ANY REGULAR POLYGON. Bisect any two angles *ABC* and *BCD*, then *E* is the centre, and a perpendicular (say *EF*) from *E* to either of the sides is the radius.

257. TO INSCRIBE A CIRCLE IN A GIVEN RHOMBUS *ABCD*. Draw the diagonals to find the centre *E*, and a perpendicular (say *EF*), from *E* to either of the sides is the radius.

258. TO INSCRIBE A CIRCLE IN A GIVEN TRAPEZIUM *ABCD*. Draw the diagonal *AC*, and bisect one of the other angles, then *E* is the centre, and the radius is a perpendicular to either of the sides.

259. WITHIN A GIVEN EQUILATERAL TRIANGLE *ABC*, TO INSCRIBE THREE EQUAL CIRCLES, EACH TOUCHING TWO SIDES AND TWO CIRCLES. Bisect each of the angles by the lines *AE*, *BD*, and *CF*, thus obtaining three equal trapeziums, in each of which inscribe a circle as in 258.

260. TO INSCRIBE A CIRCLE IN A GIVEN SECTOR *ABC*. Bisect the angle by *AD*. Through



CIRCLES TOUCHING LINES AND CIRCLES. FOILED FIGURES

D draw a tangent DE to meet either AB or AC produced in E. Bisect the angle AED by the line EF intersecting AD at F, which is the centre, and FD the radius of the required circle.

261. To Describe a Circle to Touch the Arc of a Sector and the Two Radii Produced. Bisect the angle by BD intersecting the arc at E. Through E draw the tangent EF. Bisect the angle EFG by the line FH intersecting BD in H, which is the centre, and HE the radius of the circle.

262. To Inscribe Any Number of Circles in a Given Circle. Divide the circle into twice as many sectors as circles required, and inscribe a circle in each sector (Prob. 260). The centres are found as shown by the dotted circle.

263. To Describe Any Number (say Four) of Equal Circles About a Given Circle. Divide the circle as in 262 and produce the diameters. At the point A draw a tangent BC. Then proceed as in 261. The other centres are found as shown by the dotted circle.

264. To Describe a Circle of a Given Radius AB to Touch a Given Circle C and a Given Line DE. Draw FG parallel to DE at a distance equal to AB from it. With centre C and radius equal to the sum of the radius of circle C, plus AB, describe an arc cutting FG in H, which is the centre required.

265. To Describe a Circle of a Given Radius, Touching Two Given Circles Externally. Let AB be the given radius. Find the centres C and D of the given circles, draw radii CE and DF and produce them. Set off EG, FH equal to AB. With centre C and radius CG describe an arc. With centre D and radius DH, intersect in K. With centre K and radius AB describe the circle. If the arcs were continued the centre for another circle would be obtained.

266. To Describe a Circle to Touch a Given Circle A in a Given Point B, and to Pass Through a Given Point C, Either Within or Without the Circle. Join B and C. Bisect BC by a perpendicular DE. Join B and A and produce BA to meet DE in E, which is the centre and BE the radius of the circle required.

267. To Describe a Circle to Touch a Given Circle at a Given Point A, and a Straight Line BC. *First externally:* Find D, the centre of the given circle, and draw DE through A. At A draw the tangent AF meeting BC in F. With F as centre and FA as radius describe an arc cutting BC in G. At G erect a perpendicular to BC intersecting DE in E, which is the centre. *Second, including the given circle:* Draw the radius AD and produce it beyond D. Draw the tangent AF meeting BC in F. Make FG equal to FA. At G erect a perpendicular to BC meeting AE in E, which is the centre, and EG the radius.

268. To Describe a Circle to Touch a Given Circle and a Straight Line AB at a Point C. *First externally:* Find D, the centre of the given circle, and draw DA perpendicular to AB, and produce it to E. Join EC. Through F (where EC cuts the given circle) draw DG intersecting a perpendicular from C in G. G is the centre and GC the radius of required circle. *Second, including the circle:* Find the centre D, and draw the perpendiculars AD and CG as before. Through E (the intersection of AD with the circumference of the given circle) draw CF cutting the circle in F. Through F and D draw FG intersecting CG in G, which is the centre, and GC the radius of required circle.

269. To Describe a Circle of a Given Radius AB, to Touch Two Given Circles, and Include Them. Join the centres of the circles and produce the line both ways. Mark off FE and GH equal to given radius AB. With centres C and D and radii CH and DE respectively, describe arcs intersecting at K, which is the centre of circle required.

270. To Describe a Circle to Touch Two Given Circles A and B, and One of Them in a Given Point C. Join A, the centre, with C and produce. Make CD equal to the radius of the other circle B. Join B and D and bisect BD by a perpendicular intersecting CA produced in E, which is the centre, and EC the radius of the required circle.

271. To Describe Three Circles to Touch Each Other, their Radii A, B, and C being Given. Draw any line DE, and set off on it DF and FG equal to A and B respectively. With D as centre and DF as radius describe one circle. With G as centre and GF as radius describe a second circle. Mark off FH and FJ each equal to C. With centre D and radius DJ describe an arc. With centre G and radius GH describe another arc intersecting the former in K, the centre of the third circle, whose radius is C.

272. To Describe a Circle which shall Pass Through Two Given Points A and B, and Touch a Given Circle FGC. Describe any circle passing through A and B, and cutting the circle FGC in C and D. Through C and D draw CE to meet AB produced in E. From E draw a tangent EF to the circle FGC. Then F is the point where the described circle will touch the given circle. Describe a circle to pass through the points A, B, and F [see 200].

Foiled Figures. The following problems relating to foiled figures are exceedingly useful in geometrical design for window tracery and other ornamental forms. It should be observed that in 274–282 the foiled figures are formed of *semicircular* arcs, but in 283 of *tangential* arcs.

273. To Inscribe a Semicircle in an Isosceles Triangle ABC. Bisect the angle BAC by AD. Bisect the angle ADB by DE cutting AB in E. Through E draw EF parallel to BC. Upon EF describe a semicircle.

274. To Inscribe, in an Equilateral Triangle ABC, Three Equal Semicircles, Each Touching One Side and having their Diameters Adjacent. Bisect each angle of the triangle by the lines AF, BD, and CE. Bisect the angle AFB by the line FG cutting BD in G. Through G draw GH and GJ parallel to BC and BA respectively. Join HJ. On the lines HG, GJ, and JH describe semicircles as shown.

275. In a Square $ABCD$, to Inscribe Four Equal Semicircles having their Diameters

Adjacent, Each to Touch One Side of the Square. Draw the diagonals and diameters. Bisect the angle *EFB* by *FG*, and obtain the inner square *GHJK*. Upon each side of this square construct a semicircle.

276. Within a Regular Polygon, say a Hexagon, to Inscribe as Many Semicircles as the Figure has Sides, Each Touching One Side and having their Diameters Adjacent. Divide the polygon into equal triangles and inscribe a semicircle in each as shown.

277. To Inscribe any Number of Equal Semicircles in a Circle, Each to Touch the Circumference, and have their Diameters Adjacent. Divide the circle into twice as many equal parts as semicircles required. Draw the diameters, and at the end of one of them (say at *A*) draw a tangent. Bisect the angle *BAC* by *AD*, and obtain *BE*, *BF*, *BG*, and *BH*, each equal to *BD*. Draw the pentagon *DEFGH*, and describe a semicircle on each side.

278. To Inscribe a Semicircle in a Given Square *AKBE*. Draw the diagonals *AB* and *KE*. Describe a semicircle on *AB*. Draw *CD* perpendicular to *AK* and cutting the semicircle in *D*. Join *DE*, and through the intersection *F* draw *FG* parallel to *DC*. *G* is the centre and *GF* the radius of the required semicircle.

279. To Inscribe a Semicircle in a Given Trapezium *AEBK*. Draw the diagonals. On the shorter, *AB*, describe a semicircle. From *C* draw *CD* perpendicular to *BK* and cutting the semicircle in *D*. Join *DE*, and proceed as in last problem.

280. In a Given Square *ABCD*, to Inscribe Four Equal Semicircles, Each to Touch Two Sides, and have their Diameters Adjacent. Draw the diagonals and diameters as shown. In each small square, as *BEFG*, inscribe a semicircle as in **278**.

281. In a Given Equilateral Triangle *ABC*, to Inscribe Three Equal Semicircles having their Diameters Adjacent, and Each Touching Two Sides of the Triangle. Bisect each angle of the triangle by lines which divide the triangle into three equal trapeziums. In one trapezium (say *ADFE*) inscribe a semicircle as in **279**. Make *FJ* equal to *FH*. Join *HJ* and *GJ*. Upon *HJ* and *GJ* describe semicircles.

282. In any Regular Polygon (say a Pentagon *ABCDE*), to Inscribe a Number of Equal Semicircles, each to Touch Two Sides of the Polygon, and have their Diameters Adjacent. Draw the lines bisecting the angles and giving five equal trapeziums. In each trapezium inscribe a semicircle as in **279**.

283. To Describe a Trefoil of Tangential Arcs, the Radius *AB* being Given. Construct an equilateral triangle *CDE* with sides each double of *AB*. With each angle as centre and *AB* as radius describe the arcs.

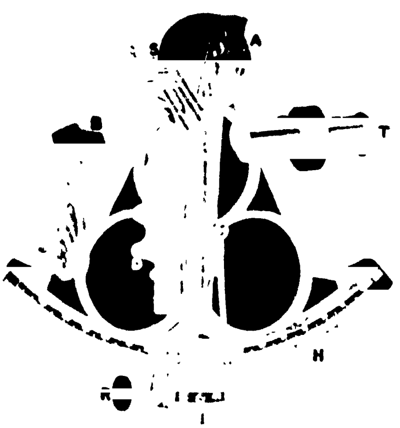
MARINE or HYDROGRAPHICAL SURVEYING

Explanation of the Sextant. Artificial Horizon and the Station Pointer. Observations of the Tides and the Use of Floats

By Professor HENRY ROBINSON

IT is not proposed in this article to refer to deep-sea soundings and other special works of an allied nature, but to confine the subject to that which comes within the province of a civil engineer.

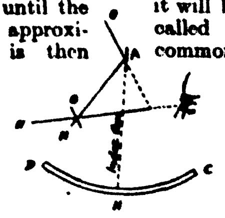
Some of the instruments that have already been described in LAND SURVEYING are also used in marine surveying. There are, however, several instruments which will be explained before proceeding with the "field" operations.



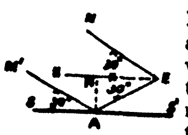
63. SEXTANT

The Sextant. This hand instrument [63] is very useful for measuring both vertical and horizontal angles up to 120°. Its construction is as follows: A mirror (A), called the *index glass*, is fixed to an index arm (I), which carries a vernier that reads on the graduated scale (H), and from it the values of the observed angles are obtained. Any movement of the index glass throws a reflection into another mirror (B), called the *horizon glass*. The latter is rigidly fixed, the lower half of the glass being silvered and the upper clear. Thus, a ray of light coming from the direction of N [64] passes through the clear portion of the glass B, down the telescope, to the eye. A ray from the direction of an object at O strikes the mirror A, is reflected to M, and then, through the telescope, to the eye. Therefore, through the telescope come rays both from the direction of N and O, each set forming a perfect image. By operating the index glass (A), images will appear to be moving over each other until the two under observation appear and approximately coincide. The index arm is then clamped by a screw, the screw used the objects until their coincidence is perfect.

65. ARTIFICIAL HORIZON



64. ARRANGEMENT OF MIRRORS IN SEXTANT



66. ANGLES OF REFLECTION

The angle between the two objects can now be read. A small magnifying glass (M) is provided to assist the observer in reading the vernier. Smoked or tinted glasses (S) of various shades are provided for use in strong light, or when taking observations to the sun.

To determine the altitude of the sun, direct the telescope on to the horizon through the clear portion of the glass B, the instrument being held in the right hand by the handle (D). Unclamp the index arm (I) and bring the reflection (made by the mirror A) of the sun on to the silvered portion of the glass B. Clamp and adjust the index arm, as previously explained, so that the top limb of the sun coincides with the line of the horizon, then read off the value of the angle in the usual manner.

The Sextant at Sea. When measuring the altitude of an object above the "sensible" horizon with the sextant at sea, a correction must be made to allow for the "dip" of the horizon—*i.e.*, its apparent angular depression below a truly horizontal line traversing the eye of the observer. The amount of this correction is uncertain owing to the variable refractive power of the atmosphere. Rankine gives a formula for finding the value of the correction:

$$\text{Dip in Seconds} = \tfrac{9}{10} \times 206264''\cdot 8 \sqrt{\frac{2h}{r}}$$

$$= 57''\cdot 4 \sqrt{h} \text{ in feet.}$$

When h = height of observer's eye above the sea

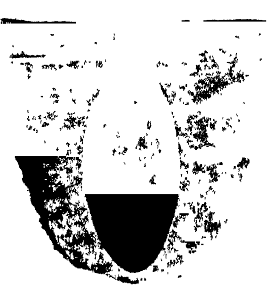
r = radius of curvature of the surface of sea.

Before leaving the description of the sextant it will be necessary to explain an instrument called the "artificial" horizon, which is commonly used with the sextant.

Artificial Horizon. The angles observed with the sextant at s measured the *sensible* horizon, which, however, is not always possible on land, therefore an "artificial horizon" is necessary. The most suitable form of artificial horizon is that consisting of a tray of mercury having a glass cover or roof. The illustration [65] shows one made by Mr. J. H. Steward. The angle observed with the artificial horizon is double the actual angle.

The theory of the instrument is described by Mr. W. F. Stanley in his book on "Surveying Instruments," and is briefly as follows.

A small luminous body [66, M'], placed at a distance will have its image reflected from a level reflecting surface [SS'], at an angle equal and opposite to the incident ray, the angles M'AS and EAS' being equal. Let E be the place of the eye or the sextant. This will receive an image from the distant body M', sensibly parallel with M'A in ME. The angle MEA will therefore be double the angle of incidence M'AS; the half angle produces the horizontal line EH (provided the plane of reflection SS' is level). Therefore, if we take half this angle MEA, as it appears in the sextant, it will give an angular position of the object in relation to the horizon at the height of the eye, or be tangential to the surface of the earth. If M'AS be 30°, the angle AEM will be 60°, showing the elevation of the object to be half this angle—that is, 30°. The sextant takes angles up to 120°, therefore 60° will be the limit of meridian altitude that the artificial horizon will measure.



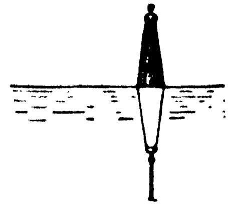
67. BOTTLE FLOAT

Tides. It is necessary for the purposes of some marine surveys to take careful observations as to the set of the tides. It will be impossible in this course to deal exhaustively with all the peculiarities of tides, but a few brief observations are necessary in order that some general information may be conveyed. Complete records of the tides in any particular locality would involve months of careful observation on account of the variations that take place at different times of the year. In one place the normal number of tides per day of six to seven hours for each rise or fall will often differ from another place which will have tides of longer or shorter duration. The reason of the varieties in the motion of tides is due to several causes, the height of the barometer being one. It is found that a high barometer accompanies a low tide and a high tide synchronises with a low barometer.

The relative positions of the sun and moon, the direction of the wind and the conformation of the land affects the tides; it is the two last that produce the greatest irregularities. The method employed for gauging the rise and fall of tides, when no pier, wharf, etc., are available, is by erecting a *tide-pole*. These poles are generally constructed out of an old spar, properly marked in feet, and firmly weighted and fixed in the sea-bed in the most sheltered place possible. To obtain the accurate time of high and low water, observations must be taken every few minutes, some little while before and after high and low water, the exact time being calculated from the results thus obtained.

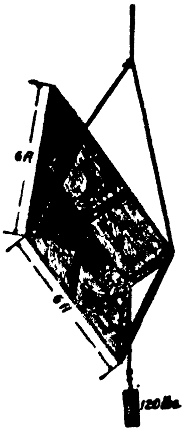
The direction of the tide must be obtained by float observations, as explained later.

It must not be assumed that because it appears to the eye that the tide is flowing in a certain direction that such is the case. Take for example a tidal river. The land water being of a different specific gravity, and warmer than that of the sea-water, will flow over the incoming tide, thus producing two distinct currents in opposite directions. This peculiarity is of extreme importance to engineers, and it is only by careful float observations that the true direction of currents can be obtained.



Floats. The direction of currents can be accurately obtained by using various forms of floats. The action of the wind on the exposed surface of a float which projects too much from the water may cause it to travel in a direction totally different to that of the current. Therefore a float must be made so that as little surface as possible is exposed to the wind. A simple and useful form of float may be constructed from a bottle, as shown by the illustration [67].

Where it is necessary to determine currents at considerable depths a float constructed as shown by 68, or something similar, must be employed.



68. DEEP-SEA FLOAT

The method of determining the position of a float from time to time is similar to that explained hereafter when dealing with the location of soundings [70].

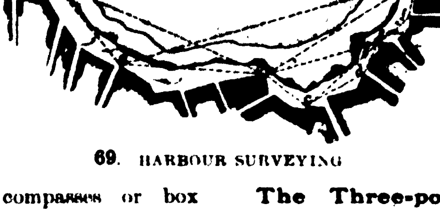
In carrying out a marine survey on a coast line, the configuration of which has been obtained by triangulation (such as shown in 69), the method to be employed must to some extent depend on local circumstances. The nature of the sea-bed must be examined either by diving operations or by borings, the results of which should be noted on the plan, or chart, by reference letters, such as "r" for rock, "s" for sand, "m" for mud, and so on.

All moorings, buoys, beacons, groynes, lighthouses, prominent rocks, etc., should be clearly and accurately shown. The bed of the sea is surveyed by *soundings* taken from a boat with a loaded line. All soundings on published charts are given (in fathoms) for low water at ordinary spring tides.

The position of each sounding can be obtained either by angular measurement from the shore to the boat or from the boat to the shore.

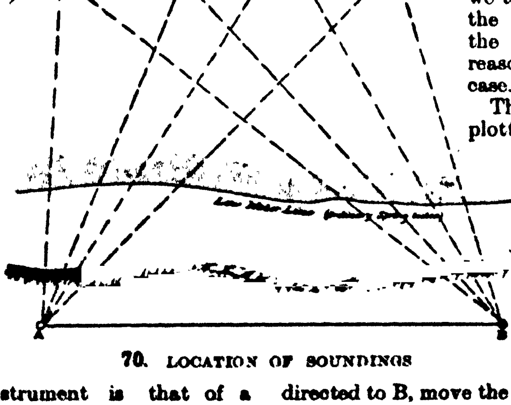
The following is a description of the first method :

Set out on the shore a base line [70, AB] of known length and position with regard to the chart or plan. At A and B set up theodolites. The observers follow with the telescopes of the instruments the movements of the boats from which the soundings are being taken. On receiving a prearranged signal from the boat, each attendant observes the angle between the boat and the base line, thus locating that particular sounding. The time also is noted. These angles can also be obtained, when minute accuracy is not required, by employing prismatic compasses or box sextants. From the angles thus obtained at the stations A and B, the position of each sounding (as shown by the points C, D, E, and F on the illustration) can be determined and plotted on the chart or plan by means of a protractor.



69. HARBOUR SURVEYING

A better and more convenient method of obtaining the positions of the soundings is by taking observations from the boat with the sextant, and then by means of the *station pointer* they can be plotted directly on the chart. The following description will explain the whole operation :



70. LOCATION OF SOUNDINGS

The Station Pointer. The illustration [71] shows the arrangement of this useful instrument, which is employed, as already stated, for plotting on a chart or plan the position of a boat from which angular observations have been taken with the sextant to three well-defined points on the shore, the positions of these points being known. The form of the instrument is that of a circular metal protractor with three arms radial to a common centre (S), one fixed (A), and two movable. The movable arms are provided with verniers and screws. The theory of the instrument is based upon the 21st proposition of Euclid, Book III., which shows that the angles subtended by the chord of the segment of a circle measured from any point in the circumference are equal.

Thus, if the angle [72] between A and B is observed to be, say 60°, the observer knows that he is somewhere on the circumference AEDB, on any part of which, as at E or D, the angle subtended by AB will be the same. The measurement, therefore, of an angle between two objects gives this information—that the observer is on the circumference of a circle which passes through two objects, the diameter of which varies according to the angle, with an equal length of AB. This will be seen by comparing 72 and 73. In the former, AEB = 60°, and in the latter, AGB = 30°. Therefore, for example, if a mariner finds that a rock exists at X, and two well-defined objects exist at A and B, he has only to take care that the angle measured between them is considerably smaller than that measured at X [73], which may be taken from his chart, to ensure his passing outside its position.

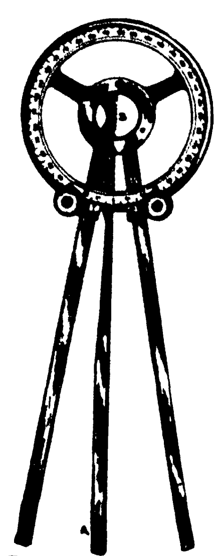
The Three-point Problem. To find the precise position of the boat two angles must be taken [75]. This is called the "Three-point Problem." It is evident that where two circles cut one another is the observer's position, for though he may be at E [74], so far as his angle between A and B is concerned at that position, the angle observed between C and F will not agree, nor will such agreement be found unless the observer is on the circle CDHF. He can only be on both circles at once when he is at D.

Suppose that instead of taking the objects CF to measure the second angle, we take it between BC [75], the observer must be at the point D for the same reasons as in the previous case.

The observations can be plotted by means of circles, or more rapidly by using the station pointer in the following manner. Set the angle ADB off on one side of the fixed arm, and the angle CDB on the other side. Place the instrument on the chart so that the fixed arm is directed to B, move the instrument about on the chart till the other arms fall on the points A and C. The centre (S) of the instrument must then be the required position, and is pricked on to the chart. If the points ABCD fall on the circumference of one circle, the point is indeterminate.

The Lords Commissioners of the Admiralty have issued a pamphlet on the station pointer, which deals exhaustively with the subject.

Soundings must be reduced to a known datum in order to connect the level of the sea-bottom to that of the shore. Soundings of equal values are usually connected together by dotted lines, as in contours on land, the value of the contour being indicated by the dots. Thus, a four fathom contour would be shown by four dots, then a space, and so on Care must be observed in connecting the soundings together, otherwise shoals, or sandbanks may appear on the chart where none in reality exist.



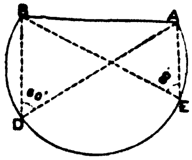
71. STATION POINTER

Foreshore Survey. The survey of the foreshore above low-water mark is carried out in the same way as land surveying. The levelling operations should be extended to, and even below, low water by the staff-holder wading into the sea. The levels so obtained are more accurate than those taken by soundings. Should the work have to be carried out at night, the cross hairs and staff require illuminating, which may be done in the following way: A mirror is soldered to the top of the cap of the telescope in such a position that it projects downwards over the object-glass, making an angle of 45° with the horizontal axis of the instrument. An elliptical hole is cut in this mirror. A lantern supplies the light, which is reflected on to the cross hairs. The staff can be illuminated by a torch, and is thus easily observable through the elliptical hole in the mirror.

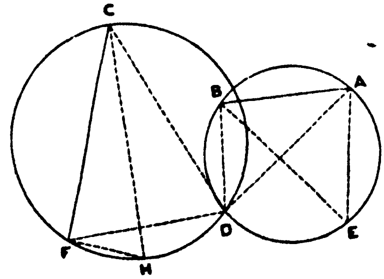
Base by Sound. The length of a base line can be obtained by sound. Although this method is not accurate, it may be employed when only approximate measurements are necessary. It consists in taking the interval of time which elapses between the *sight* of a flash from a gun and the arrival of the *sound*, the observer being at one end of the required base line and the gun at the other. It is preferable to have both a gun and an observer at each end of the line taking alternate readings. The time should be taken by chronometer watches, the beats of which are recorded by the ear and not by the sight, the number per second being thus accurately obtained. The chronometer is held to the ear and the beats counted as nought, nought, etc., until the flash is observed, and then one, two, three, etc., until the report is heard. The mean time of a number of observations, arithmetically obtained, is not correct on account of the acceleration when travelling with the wind being less than the retardation when travelling against it. The following formula must be applied:

$$T = \frac{2tt^1}{t + t^1}$$

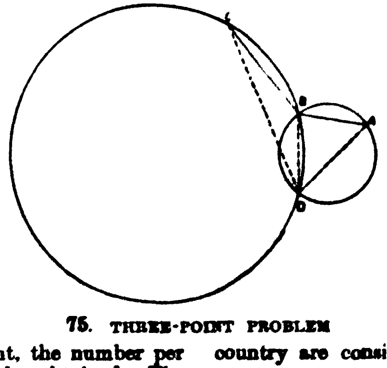
when T = mean interval required; t = interval observed one way; t^1 = interval observed the other way. The mean time (T), multiplied by the velocity of the sound for the temperature at the time of observation, will give the distance between the two places.



72. EXAMPLE 1



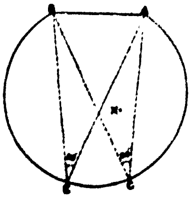
74. INDETERMINATE POINT



75. THREE-POINT PROBLEM

Sound travels at the rate of 1,090 feet per second at 32° F., with an increase or decrease of 1·15 feet per second for each degree of rise or fall in temperature.

Synopsis. The point which we have reached marks a definite stage in our study of civil engineering. This instalment concludes the teaching of Surveying, except for the references which we shall have occasion to make in describing the constructional part. The scheme of our treatment to follow may be indicated. The next article describes the history and practice of the Ordnance Survey, with information regarding the value of the different scales for different purposes. The procedure usual and necessary in seeking to obtain parliamentary powers for public and private works is explained in detail. Then we proceed to study the practice of civil engineering. The course concludes with a description of civil engineering abroad, and the diverse influences, such as climate, labour, transport facilities, etc., which modify the practice from that usual in this country are considered.



73. EXAMPLE 2

OIL & WATER COLOUR PAINTING

Painting in Oils—continued. **Setting the Palette. Brushes and Painting Ground. Water Colours. Tempera Painting. Fresco Work**

By P. G. KONODY and HALDANE MACFALL

Setting the Palette. We now come to the setting of the colours on the palette. In their order of arrangement artists vary. Some set black at the left end, and run up through the blues, to greens, to browns, to reds, to yellows, to white at the other end [1]. Some put white in the centre, and run off to the right through the yellows to reds and browns, and then run off towards the left to greens, to blues and to black. On the other hand, Whistler's palette was as shown in 2. He considered this eminently scientific. But a far more scientific setting would be to put black in the centre, as in 3.

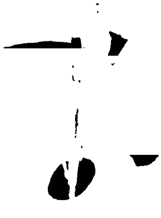
Brushes. The choice of brushes, sable or hog, round or square, is very much a matter of personal taste. Every artist has his own predeliction, which is to a certain extent ruled by his touch. For small work and delicate detail fine sable brushes are indispensable, but the large square hog brush is more useful for the laying on of broad tones, or for crisp modelling on a large scale. A round brush should invariably be used for drawing the outline. The student will soon find which brushes best suit his style, but he should at the beginning have a fairly large assortment of sable and hog brushes of different sizes. The great drawback of the former is, of course, their high price, which is probably the cause of the introduction of hog brushes. As far as can be ascertained, many of the old masters appear to have worked entirely with hair brushes, and it is very questionable whether hog brushes were at all in use before the eighteenth century.

1.

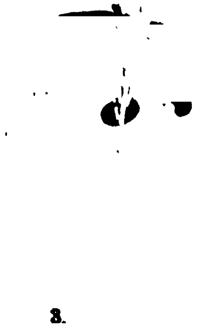
The Painting Ground. Some artists paint on the grey surface of the prepared canvas. Some tone the whole canvas a warm brown. It is with some the practice to mix in the centre of the palette a mass of the general tone of the picture, and to pull each colour through this as they paint, so as to keep the general harmony. But the methods of painting vary with the different schools.

Having sketched roughly in charcoal the general scheme, the artist either paints it in in black and white, or he starts away to paint it "direct." The use of charcoal for the first rough sketch, for "spacing" the composition on the canvas, is, however, avoided by many artists, who prefer to draw the outline immediately with the brush in monochrome, as the charcoal is apt to make the ground gritty. Whenever this method is adopted, it is advisable to do the preliminary "spacing" with charcoal on a sheet of paper, and, when the rough outline of the picture has thus been settled, to copy it on to the canvas.

The method of brushing also greatly varies. There is one school that builds up by careful brushing, there is another school that paints "direct"—that is to say, the brush is charged at each stroke with the true value of colour, and the brushful is then made to draw the form on the canvas in a stroke, and is not again touched or cross-brushed, but left when the stroke is completed. Yet a third school builds up colour with little touches of the three primary colours laid side by side.



2.



3.

Methods. Again, as to the thickness of the paint, some artists paint with the brush loaded with thick colour; others use a full, very moist brush. Each method has its advantages and its drawbacks. The school that paints the picture first in black and white, then runs transparent glowing colour over the modelling, and so employs this "glazing," as it is called, to give colour to the solid painting below it. But this method looks weak beside the forceful, direct method of vigorous paint, such as Velasquez's of old, or Whistler's or Sargent's in our own day. The "direct" painters usually paint the whole canvas at once, carrying forward the picture as a whole each day; the more detailed school paint, say, the head in a portrait first, then paint up the rest to it afterwards.

In painting, the student should always try to get the effect of the volume of air about the object, which gives so much of beauty to its colour values. Faces or objects seen at a certain distance have no hard and harsh outlines, but are seen, as it were, through a veil of intervening atmosphere. The student will easily realise, for instance, what distance gives to colour by putting up a white handkerchief before him, and seeing how white it is against a dead-white object across the room.

Style. The student has now learnt to set his palette, choose his colours, and clean his brushes. He should attack his painting by always trying to get his colour absolutely true, and then putting it upon his canvas boldly, as if he drew with the brush. He will be drawn to express himself after the manner of some particular master, and there is no better schoolmaster for him than the great, whom he should endeavour to rival, and, if it lie in him, to beat.

Each, according to his taste, will be drawn to a certain style. The broad, largely spaced manner of a Brangwyn will appeal to one, with his swinging line, telling masses, and great, wind-filled skies; whilst the extreme delicacy of an Orchardson will appeal to another. The large manner of Paolo Veronese will stir the senses of one with its sense of majesty and grandeur, whilst the solemn dignity of a Leonardo da Vinci will move another, and the decorative charm of a Botticelli appeal to the taste of a third. The broad, masterly painting of Velasquez will teach one the lesson of his art; the Japanese beauty of arrangement, simplicity, harmony, and exquisiteness will enthral another. But whether the student seek after the larger manner, the daintier, or the more exquisite, he should remember above all else that it is by colour, and by the sense of colour that his painting creates, that his art as a painter will eventually be judged—a sculptor by his form, an illustrator by his rhythmic beauty of line.

Painting in Water-colours. In painting in water-colours, the same rules apply as to the choice of colours as in the case of oils, only, perhaps, to a greater degree, for water-colour is used very thin and transparent, and is more easily destroyed by dust and damp. The following list gives a good range of safe colours, but it should always be remembered that the madders are not absolutely stable rose pigments, and that vermilion is liable to turn black.

Ivory black.
Charcoal grey.
French ultramarine.
Cobalt.
Viridian (transparent oxide of chromium).
Light red.
Venetian red.
Indian red.
Rose madder.
Madder carmine.
Purple madder.
Opaque oxide of chromium.
Burnt umber of Cappagh.
Burnt umber of Cappagh brown.
Raw umber.
Burnt sienna.
Raw sienna.
Chinese vermilion.
Yellow ochre.
The three cadmium yellows (deep, orange, and pale).
Aureoline.
Lemon yellow.
Chinese white.

As is the case with oils, there are several water-colours that were much used in the last generation which are more than faulty, if not absolutely bad. Gamboge was a villainous yellow, and Hooker's green, sap green, indigo, Prussian blue, Antwerp blue, Vandyke brown, and sepia, all fade with time. The chrome yellows are detestably bad, and injurious colours to use, as well as the beautiful emerald green, Naples yellow, orpiment, and the lakes. Red lead, also, is death to other colours.

The colours for water-colour painting in pans are better than those in tubes or dry cakes. The pans being moist, yield up their pigment easily and quickly—a very important matter in water-colour painting, and still more important in sketching. The best box to hold these "pans" is the black tin water-colour box sold by the artists' material dealers, with a place for the brushes, and flaps for use as palettes.

As regards white, the artist should be careful to avoid all whites that contain lead, as these turn dingy and end in absolute blackness in quite a short while. The best white to use is pure *Chinese white*, which is not only quite permanent, but has the additional merit of preserving good colour when bound with it.

As regards black, the *charcoal grey* used by black-and-white artists is a beautiful black, yielding exquisitely pearly greys and deep velvety darks. Indian ink is a brown black, and can be washed over. Lampblack is a deep, strong black.

Brushes and Painting Surface. A very few brushes, if good ones, will last for years. Three or four black or brown sables of varying size are all that are required; indeed, one good medium-sized brush will give all degrees of point necessary, if one also have a flat "camel-hair" for laying in broad washes, or for moistening the paper.

In water-colours the effect of the washes depends greatly upon the surface on which they are placed; the white paint in oils is, in water-colours, replaced by the white ground on which the more or less transparent washes of colour are dependent for their tone. The best paper is white, and should be strong and smooth in surface, except where rough surfaces suit the particular handling of the individual artist. The Old Water Colour Society's paper is the best in the market; whilst several firms also provide good hand-made thick *linen papers*. Before painting on a paper it is always best to run a wash of very slight tint over the whole; this will betray grease-spots and mildew, and the best way to get rid of them is to avoid the paper that betrays either.

The old-fashioned system of stretching the paper on a drawing-board is now almost superseded by the use of "sketching-boards," the paper being pasted down to cardboard, and saving infinite pains and trouble. The student should avoid tinted papers, and learn to use the white ground, to yield him the beauty of translucency which is so valuable in water-colours.

It should be remembered also that very often when the colour does not run easily upon the paper it may be the fault of the hardness of the water. In this case distilled or boiled water will make all the difference.

If the paint in the pan goes dry, a little warm distilled water will soften the hardened gum of the pigment, if left to soak.

The Choice of Colours. Now, with his colours, his brushes, water, and good white paper, the student is ready for work. With a pencil he sketches in the main lines, and then proceeds to wash in his masses. He has to choose between the two schools of water-colour painters—the Transparent Colour School (or purists) and the Body Colour School.

The purists do not use opaque colour, and, above all, will not allow the use of Chinese white in their washes. The body-colour men use white floated through their tints, and also use opaque colours solidly. The former is unquestionably the more legitimate method, and the student would do well in the beginning strictly to avoid all opaque colour. The true beauty and value of water-colour lies in its luminous transparency, and this is lost by the use of body colour.

The colours, whether solid or transparent, may be used broadly in washes to give broad effects, or they may be used minutely in what is called stipple, to give minute detail. But to whatever school of painting the artist may belong—the transparent, or wash school, or the body-colour school, the broad, impressionist school, or the stippled, detail school—there are certain laws that apply to all. He should wash in his background at the same time that he paints his main objects, so as to give those objects their full value; otherwise he will find that the white paper of the background has forced the value of his objects, so that when he tones down that background the objects look poor and weak.

Some Hints. The student must, as in oil painting, master the simple rules of perspective, and, if a figure painter, master anatomy.

Remember always, in painting in the open, not to paint your sketch at all hours of the day. Go back and paint under the same conditions of time and sunlight.

Master the rapid making of greys with, say, light red, cobalt, and yellow ochre, and so on.

It is always wise to wash in your backgrounds first; then you have not the ugly tendency to get your main objects out of their atmosphere.

Here, again, as in oils, let the student study the masters of his craft—the old men like the grand master Cotman, and the great men of to-day like Sargent. Look what Sargent and Brangwyn can do with their broad, sweeping masses, knowing exactly where to place them. Randolph Caldecott, again, is a fine master to teach the value of broad washes. Let the student haunt the exhibitions also, and study day after day the work of men he admires, and try, when he gets home, to rival them from memory. Melville's work is very masterly and telling.

In painting, brush in the mass of a thing first; and with a full brush, or a brush charged with clean water, fill in or take out detail as you want it.

Cotman of old, and Sargent, Whistler, George Clausen, Charles Green, Crawhall, Alexander, Pryde, and the like to-day all have lessons to teach us. But do not *copy* too much. A few copies from one master should never be exceeded. Master their methods, and use them to help the style you wish to evolve.

What will trouble the student much in water-colours is the hardness of his edges. He can, and should, avoid this by damping his paper *slightly* before painting upon it.

Methods of Working. Perhaps it will be some guide to the student to give the method of working of one or two of the great English painters.

David Cox's manner of painting was simple in treatment. He only used the barest pencil outline—often none at all. He then washed in his masses with many superimposed layers of colour, beginning with a ghostly picture of the landscape, and building it up as a whole, always keeping his work transparent and pure in values, and most carefully preserving the sense of atmosphere throughout. His drawings have a resulting effect of facility and freedom of labour and from heaviness that make his work a great achievement. He unfortunately used a wretched palette—gamboge, lake, Prussian blue, indigo and sepia, being amongst his twelve colours. He spoke passionately against the use of white in water-colour work.

The "Wet Manner." Prout outlined his work in brown ink and tinted in the whole.

De Wint painted boldly in the "wet manner," saturating his paper with water, and then floating on to it his colours in a full brush whilst the paper was quite wet. He never interfered with his masses afterwards. He used two large brushes, one with a fine point, the other round and blunt. He, too, unfortunately used amongst his nine colours such wretched pigments as purple lake, Prussian blue, indigo, gamboge, brown-pink and sepia, and his reds killed the blues as time wore on. He only used white, and that for his lights, towards the end. In his best work he "left out" the lights as pure white paper.

Whistler ran Chinese white through nearly every wash; and achieved such atmosphere as it would be difficult to surpass. Yet he was so incapable of using pure wash that when trying to paint on ivory he gave it up, because the white would get in, and the value of the underlying ivory was thus lost. Sargent uses water-colour in big washes of pure colour, using white only to enhance the high lights.

Long before the invention of oil painting, with which the brothers Van Eyck are generally credited, artists in Italy and in the North practised another method, which, after having been neglected for some centuries, has lately come once more into favour, though the practice of this art of *tempera painting* is still confined to a comparatively small group of artists. Fortunately, Cennino Cennini, an early 15th century Italian painter, has left us a treatise on painting, in which all the methods in use at his time are technically described. An admirable translation of "The Book of the Art of Cennino Cennini," by Christiana J. Herringham, which has been published in an inexpensive form by Mr. G. Allen, is accessible to every student, and will be of invaluable help to anybody who wishes to master the technique of tempera painting.

Tempera Painting. Cennini has well defined the nature of tempera painting. "It is true," he says, "that pictures are painted just as I explained to you to work in fresco, with three exceptions. One is that you must always paint the draperies before the faces. The second is that you must temper your colours always with yolk of egg, and thoroughly tempered, always as much of the yolk as of the colours you temper with it. The third is this: That the colours must be ground very fine—well ground—just like water." Tempera painting is thus painting with yolk of egg as medium. The advantage of the method lies in the transparency and purity of the colour, which cannot be rivalled by oil-paint. Moreover, tempera colour is permanent, and not subject to chemical processes of disintegration. Most of the tempera pictures of the early Italian and Flemish masters have preserved their pristine bloom and freshness to the present day.

On the other hand, tempera is a most difficult medium to handle, and will never yield the depth of shadow which can be obtained by oil-colours. It requires very precise drawing, because corrections are difficult to make; while delicate gradations, such as can easily be produced with oil-colours, are practically impossible to get with this method. Tempera can only be recommended for decorative work in more or less flat tints. It is almost useless in the hands of the modern painter who aims at realism, at the life-like, plastic appearance of things, and at atmospheric effects. Tempera colours could produce a Botticelli, but never a Rembrandt.

Surface. The best surface for tempera painting is offered by wood panels, which can be bought ready for use from artists' material dealers. Since a demand has sprung up, various preparations of tempera paint have been placed on the market, but it is best to follow the example of the old masters and prepare one's own material. An immense amount of disappointment will be saved by a judicious selection of the wood required for the panel. If possible, this should be old, well-seasoned oak. The planks of old boats are admirable for this purpose, as they are not likely to warp.

To guard against any action in the wood, the back of the panel must be specially strengthened by strips of wood criss-crossing, and fixed so firmly to the panel that it is impervious to the injurious effects of heat or damp. The next step is to make a preparation, with which the wood is covered to get a delicate surface for the tempera paint.

Take a quantity of plaster-of-Paris and leave it to soak in a tub of water for two or three months. This is to destroy the life in the plaster, which is liable to ruin the colours if the mixture is used too soon. The preparation should be stirred well every day for a few weeks. Then the water can be poured off, and the plaster rolled into cakes. These are the balls of *Gesso*, ready for further preparation.

The Method. This gesso is ground to a powder and mixed into a smooth paste with water. Melt some carpenters' glue, and while it is boiling pour it into the gesso paste, which must previously be warmed to prevent the glue from thickening immediately. The paste and glue have to be well stirred together. There is an easy method for finding out whether a sufficient quantity of glue has been added. Pour a little of the mixture on to a piece of paper and dry it over the fire. Moisten the finger and rub the gesso; if any white comes off on the finger, it is a sign that the mixture does not contain enough glue.

It should be remembered that glue can always be added, but that it cannot be taken away from the mixture. It is advisable to give the panel a preliminary coating of glue, but this is not absolutely necessary. Apply the gesso, while it is rather stiff, with a brush, and spread it evenly over the surface—not too thickly, but it should not be transparent—and leave it to dry. When the preparation has become hard, rub the surface down with fine sandpaper to a convenient degree of smoothness. This is, of course, a matter of personal taste. If the tempera is laid on too thickly, it is liable to chip at the sides.

Dry Ground. To prepare the tempera for a dry ground, take only the white of an egg, mix very stiffly with the powdered earth colours that colourmen sell. The medium to use is the white and the yolk of egg beaten up, and mixed with a little water, or, better still, only the white of egg and water. The great advantage of tempera over oil is that it dries almost immediately. It can be used on canvas, or even on paper, but the most delightful effects result from its being applied transparently on the gesso surface.

In many of the masterpieces of the greatest workers in tempera it will be seen that many of the small details of the picture are raised in relief, such as the crowns and the halos of saints, or the embroidery on the richly decorated garments. There are some very remarkable examples of this raised work in our National Gallery, notably some of the pictures by Carlo Crivelli. This moulding is all executed in gesso—that is, in the substance which has already been described as a suitable basis for tempera painting. Only, for relief work it is made with less liquid and more glue, and applied very stiffly with the brush, layer above layer, until the desired relief is obtained. Then, when the artist is satisfied with the plastic shape, the surface is painted and gilt to get the desired pictorial effect. This method has been successfully revived in recent years by some Birmingham artists, who have produced some delightfully quaint and effective caskets, chests, and other decorative objects in mediæval taste.

It may be useful to the artist to know that fairly reliable tempera colours can be obtained from a German firm in Düsseldorf, who have made a special study of this medium, and who have issued a catalogue in which the colours, which are guaranteed to be absolutely permanent, are specially marked.

Fresco. Fresco painting is the term applied to paintings executed on a wet plaster ground, for which purpose tempera colours are generally used. In fact, fresco work is the ideal application of this difficult medium, since large decorative mural paintings should accentuate the flatness of the wall rather than deceive one into believing that the wall opens to reveal a glimpse of real life and nature; and this deception, which is one of the chief aims of most modern painters, can only be achieved with oil colours.

The Italian masters of the fifteenth century were the ideal decorative painters. Painting direct on the wall of church and cloisters and palace, they were forced to consider the surroundings, and realised that wall painting should have no independent existence, but be the handmaiden of architecture. Many modern painters do their decorative work in the studio without thinking of its ultimate destination. The result is that when the canvas is fixed in position on the wall, it probably looks incongruous and detracts from, instead of adding to, the effect of the architectural setting. But a great improvement has lately set in in this direction, and we have now a few artists who, like Frank Brangwyn, are fully appreciative of the exigencies of decorative work.

The First Consideration. The first technical consideration should be the surface of the wall chosen, which must be specially prepared. Procure, in the first place, the necessary quantities of lime and sand, according to the space that has to be covered. Sift both, so that they are entirely free from lumps. If the lime is very fresh it will require the addition of twice its quantity in sand. Mix these materials with water, and allow the lime to rest for some time to avoid the risk of bad cracks when the plaster is dry. The surface on which the fresco is to be laid must be well cleaned and drenched with water. Having thoroughly stirred the lime and sand, spread it evenly, in one or two applications, on the wet surface until the mixture itself settles to form a new, flat ground.

That this flat surface should be rough in grain is an advantage. This quality is obtained by mixing the mortar with as little liquid as practicable. In a few hours the preparation will be dry and ready to receive the artist's first design, which should be in charcoal, as any false lines in tempera paint would immediately become one with the plaster, and therefore ineffaceable. When the drawing is correctly executed in charcoal, the outlines should be drawn in with ochre or sienna, and the charcoal brushed away with a feather brush. Before the actual painting is begun the mixture of lime and sand must be repeated. It is *most* important that the whole picture should be painted while the plaster is wet, so that the paint and plaster amalgamate, become absorbed into each other, and make one perfect whole, which should withstand the attacks of time and weather. From this painting on a fresh plaster ground the whole method has received its name—the word *fresco* being Italian for fresh.

Surface of the Plaster. Since it is impossible to paint at once over the whole surface, the artist must spread this second mixture of lime and sand thinly over just the amount of wall space which he can cover with paint in one day. Having already marked the first simple outlines of his picture, he should follow these, filling them in with the wet plaster, so as not entirely to obliterate the skeleton of his design. Every day another portion is thus added, until the whole picture is completed. It cannot be insisted upon too emphatically that the essential point in fresco painting is the wetness of the plaster which receives the paint. This second coating of plaster must be applied lightly, and for this purpose a brush of hog-hair should be used, steeped in clear water, and the mortar wetted with it. A strip of wood as broad as the palm of a man's hand is passed over the surface to remove any surplus plaster and to distribute it quite evenly over the section chosen for the day's work.

In case of any accident or change in the design, the faulty part must be soaked off bodily, painted and plastered together, and a fresh surface created. From this it will be seen how important it is that the first design should be quite correct, as a small fault requires such drastic correction. The medium for this fresco work is a special form of tempera, which can be made by the worker himself.

Beat up the yolk and white of one or two eggs with water. The paints used in fresco are the powdered earth colours obtainable from all colourmen. This powder must be made into a thin paste, well mixed with the egg and water. When being applied to the wet plaster, the paste must be still further diluted, so that it may mingle and become one with the ground. Once more the necessity for wetness in the plaster and liquidness of the paint must be insisted upon. For fresco painting on canvas the method is the same.

A SURVEY OF FLAX, HEMP AND JUTE

The English, Scotch, and Irish Linen Trades. The Manufacturing Processes Reviewed. Canvas Floorcloth and Linoleum. Rope Spinning

Group 28

TEXTILES

7

Continued from page [illegible]

By W. S. MURPHY

LINEN cloth has always been held in high esteem by cultured nations.

It was not till the tenth century that the linen industry of Europe came into historic prominence, when the Flemish town of Ypres became prosperous and important on its linen manufactures, the speciality of which was a fine cloth, since called *diapers* among ourselves, an evident corruption of "d'Ypres."

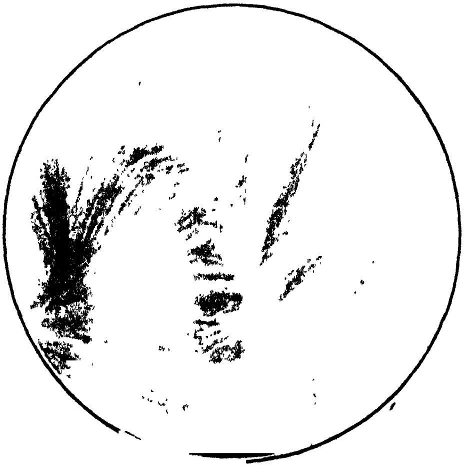
British Linen Manufacture. The first mention of Irish linen occurs in the thirteenth century. In Scotland the trade must have been important about the same period, because the bodies of the Scottish foot soldiers unearthed in the last century on the field of Bannockburn were clad partly in linen. The large trade of England, being carried on in each little parish for local consumption, totally eludes observation before the year 1720, when the fibre appears as the universal provider of warp for cotton, which could then be spun only for weft.

At present there are four important centres of the trade—*viz.*, Belfast, Manchester, Leeds, and Dundee.

Just at the time when cotton was coming to drive English linen out of many markets, the rival fibre stimulated for a short period the production of linen yarn. Up till the year 1773, cotton could not be spun strongly enough for cloth warps, and linen was used.

During the latter half of the seventeenth century, the Irish linen industry, quietly practised for centuries in the Ulster province, received a fresh impetus from the invasion of skilled weavers of cambrics from Picardy, driven thither by the Revocation of the Edict of Nantes.

Lisburn, Ballymena, Armagh, Coleraine, and Lurgan were the chief centres of the linen industry, and to these towns Belfast is the nearest great seaport. Having a fair share of the industry itself, Belfast became naturally the emporium of Irish linen. When the factory system began to supersede hand-production, mills were built in Belfast, and the seaport quickly attained first rank as a linen manufacturing town.



31. FLAX FIBRE

As we have already indicated, the linen trade of Scotland is of old standing. Two of the principal centres of the industry are Dundee and Dunfermline, the former in the coarser linens, and the latter in damasks and diapers. The history of the Dundee linen trade strongly resembles that of Belfast.

About the close of the seventeenth century, a small colony of Huguenot linen weavers had settled in Edinburgh, on the spot now known as Picardy Place. Some of these weavers migrated to Dunfermline, helping materially to establish that reputation for damasks and fine linens which Dunfermline still enjoys.

The Manufacturing Processes. In many respects, with all our progress, we have not advanced beyond the methods practised five thousand years ago. The spinning wheel which we illustrate [82] by a picture lent by Messrs. Bannerman & Sons, Ltd., Manchester, contains the principle of flax spinning, and all our machinery is little more than an elaboration of that contrivance. Our young men have plenty of scope for their ingenuity in the improvement of linen manufacture. The process is a long series of graded operations. We will take up each stage of the process in detail, but a short summary may be given here.

1. *Retting* frees the fibre from the rest of the stem.
2. *Scutching* breaks off the woody substance still clinging to the fibres, and tends to open them out.
3. *Roughing* gives the fibres a preliminary clean, sort, and range.
4. *Hackling* combs out the fibres, separating the short from the long.
5. *Sorting* classifies the fibres.
6. *Spreading* is a kind of rough carding, which lays the fibres alongside each other, and forms them into a sliver or soft rope.
7. *Drawing* lengthens out the slivers and gives them the form of thread.
8. *Roving* continues the last process, and prepares the thread for the spinner.
9. *Spinning* refines, twists, and forms the thread by means of successive machines.
10. *Reeling* winds the spun yarn into hanks.

11. *Winding* forms the spools of weft for the shuttles of the loom.

12. *Warping* lays the warp yarn on the dressing or weaving beam.

13. *Dressing* coats the thread of the warp with size, to strengthen it for the weaving.

14. *Healding* sets the warp in position for weaving on the loom.

15. *Weaving* unites warp and weft in cloth.

16. *Bleaching* whitens the cloth.

In addition, we have to see the flax fibres made into thread for lace-making and sewing. Many of these processes are almost identical with some of the processes in cotton, wool, and silk manufactures ; and while the linen industry must always be studied as a distinct entity, the plan of our course has been arranged so that all the textile workers having a common interest in any machines or methods may study them together.

The linen manufacturer produces a vast range of goods—from the lightest of cambrics to the coarsest of canvases ; from the plainest of sheetings to the most beautiful of damasks and brocades ; and from the finest of lace threads to the strongest of cables. This brings him into close competition and association with the workers in hemp, jute, and other fibres of that class.

Jute Manufacture. So closely related in treatment and product are all the best fibres that it is almost a pity they are not united as one industry. We can hardly say, however, that a lad who has been taught the linen industry is, on that account, equipped for work in a jute mill in all its departments. In actual fact, reasons historical, economic, and industrial forbid that desirable event, and we must meanwhile take things as they are.

Softening. The retting, scutching, and baling of the jute fibre take place in those tropical lands where it is grown—at present, almost exclusively India. When we receive the jute fibres they are fairly clean, long, and lustrous ; but we also find them harsh and brittle. For more than half a century these defects hindered the development of the jute industry in this country. As has been already stated, the problem was solved by the invention of the softener. The bales are opened out, and the fibre formed into *stricks* or *strikes* by the attendant on the softening machine, or his helper.

A vast combination of fluted rollers and oil-distributors, ingeniously devised, the softener delivers the fibres in a condition equal to flax in flexibility. Thence, jute follows a process of manufacture similar in its main details to that of flax, already detailed.

Jute not only rivals flax for many purposes, but it also has a department almost to itself, worthy of special note.

Floorcloth and Linoleum. Floorcloth was originally invented by Nathan Smith, in 1763, and patented by him as a substitute for carpets. He must have been something of a poet and hygienist this Nathan Smith, because there was a curious mixture of sentiment and sanitation in his idea. Jute was not known at that time. Mr. Smith's idea was to use the flax fibre and the flax-oil—linseed-oil—for the production of an ideal floorcloth, thus utilising all the product of the plant in one fabric. Jute, as the bulkier, softer, and cheaper fibre, displaced flax in the body of the floorcloth, but the method of manufacture remained practically the same.

Floorcloth is a canvas saturated and covered over with paint. Paint is a dry colour mixed with some kind of oil, and as linseed-oil is a quick drier, it is well suited for the floorcloth manufacturer's purpose. Each coat of paint must be dry before the next is laid on, and if the paint did not harden quickly, the process of manufacture would be tedious and costly. The process of manufacture is very simple. The canvas is primed—that is, coated back and front with size. The size is scoured smooth with pumice-stone, and then the thick linseed-oil paint is applied thickly, and spread smooth with a trowel. After drying for 12 or 14 days, it is smoothed well with pumice-stone, and coated with paint as before. The back is now solid ; a coating of size is applied to the front side of the canvas, which is treated in the same manner as the back. For high qualities as many as four coats of paint are laid on the right side of the cloth. In this condition it is plain, and by giving it a coat of varnish we might send it out as plain floorcloth. But the common taste demands some kind of ornament. We therefore proceed to print on the surface a pattern or design, by means of paint-covered blocks, which leave the coloured lines and masses standing out in relief. When sufficiently dry, it is varnished over, and again dried.

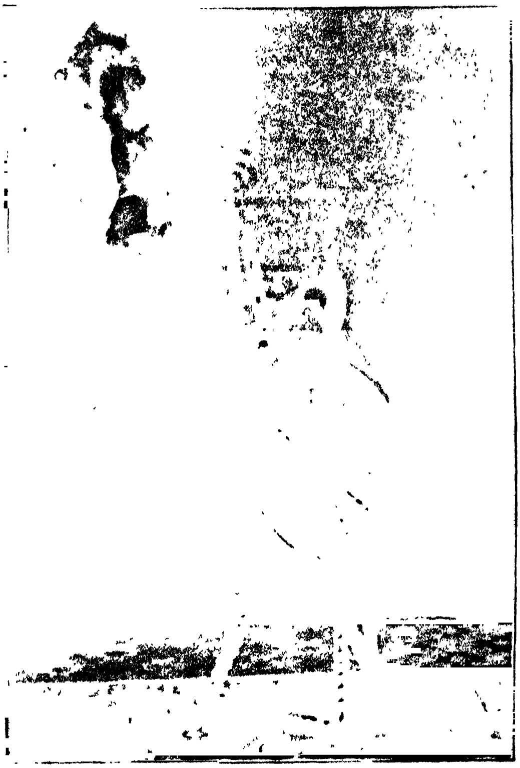
Such is the old-fashioned process of floorcloth manufacture. We shall, when the whole process is being studied in detail, show the various improvements made and machinery used in the modern factory ; but, in the main, the methods are the same.

Cork and Improved Linoleums. Though floorcloth had many merits, it failed in competition with carpets because of its hardness, coldness, and lack of sound-deadening qualities. This led to many attempts being made to produce a softer cloth of similar manufacture. In 1844 Elijah Galloway took out a patent for a fabric he named *kamptulicon*, made from ground cork and indiarubber, amalgamated by the action of heated rollers. This fabric attracted considerable notice when shown at the Exhibition of 1862, and several factories were started for its manufacture. It was used in many great public buildings, notably the Houses of Parliament ; but the materials of which the fabric was made rendered it costly, and beyond the reach of all but the wealthy classes.

In 1860 Mr. Frederick Walton conceived the idea of making a substitute for indiarubber from linseed oil, and three years later took out a patent for the application of this material to the production of floorcloth. By melting oxidised linseed oil with kauri gum and resin, mixing the mass with ground cork, and rolling the material thus obtained on a canvas back, a floorcloth was manufactured quite equal to Galloway's fabric, and much cheaper.

The new floorcloth was named *linoleum*, and had some success, as well as rivals, most notably the fabric called *corticine*, made by a similar process, but discovered independently.

Later developments in linoleum manufacture have chiefly been in the direction of rendering permanent and artistic the patterns and designs popular taste demands on floor coverings—whether composed of floorcloth or carpet. The stages of the progress linoleum manufacturers have made in this direction are interesting. As is well understood, a merely surface pattern quickly disappears from linoleum under the tread of many feet. To give an indelible surface, Mr. Walton devised a cork covering composed of different coloured granules, imposed on the canvas and pressed with heated rollers, producing granite pattern. Next, the cork covering was made up of small pieces, coloured to form a design, and impressed on the backing, the result being a kind of mosaic. This, however, lacked the plasticity demanded by art, and other attempts were made, bringing out two methods of inlaying—one called the "grid," and the "other the "stencil." In the one, the small pieces of differently coloured cork composition were definitely moulded; in the other, they were coloured by a stencil process. The former, it was claimed, gave clearer outlines; but for the other, the merit of softer effects was asserted.



32. SPINNING WHEEL

Ropes and Twines. If antiquity or primitiveness be a merit, the ropemaker should take a high place. The art of spinning is merely a making of ropes; weaving is the plaiting of cords. Most probably the first of the textile industries, ropemaking was certainly the last to be noted by the inventor and the capitalist. Carried on in small country villages, or in the back streets of seaports—for purely local consumption—ropemaking was scarcely recognised as an industry till the beginning of the 19th century. Yet in the days before the steamship ropemaking was one of our greatest imperial assets; on the strength and toughness of her shrouds and cables the safety and power of the ship depended. Southey tells us that Nelson, just after he received his death-wound, observed that the tiller-ropes of the Victory had been shot away, and ordered new ones to be rove. Woolwich Arsenal originated from the ropery in which cables and sail tackle were made. All round the coast for centuries the ropemakers and net-makers have plied their useful craft; but they made for home and local consumption only, and therefore did not come within the purview of the statistician, the wealth they created passing unnoticed into the coffers of the Empire.

Scope of the Industry. Twine and ropemaking is an industry which extends much farther than most people are aware; it includes bootlaces, staylaces, and window - blind cords; twines, nets, lines, and netting; pulley-ropes, driving-ropes, crane - ropes, cables and hawsers; wire ropes, of steel, iron, brass, and copper, and many small specialities.

Materials Used. The rope factory is the last resort of textile fibres rejected by the spinners of cloth yarns. Ropemakers have no reason to object to this, because the practice has brought to the industry many very useful and cheap fibres. Our raw materials comprise nearly all the vegetable fibres, the sole condition of use required of any fibre being cheapness and suitability for either general or special purposes. In addition, ropes are made of iron, steel, brass, and copper. Paper and glass could be utilised, and might serve special purposes very well, but these materials have not yet been employed to any extent.

Roperies. Primitive in its origin and essential character, the rope industry did not attract the machine inventor for a long time Up till near the close of the 19th century the rope-spinner might have been seen working on the open fields, in agricultural districts remote from railways and the tracks of traffic. A lone figure comes walking backwards across the field, lengthening out a strand of rope at every step, while at the far end a lad is working a whorl, in the hook of which the end of the strand is fixed. From round his waist the man draws wisps of hackled hemp, and keeps twining it on to the strand, feeding with one hand, and with the other holding and regulating. We need hardly observe him further, for that man has been practically unemployed several years.

When rope-spinning ceased to be an open-air industry, largely dependent on weather conditions, the path of the spinner was roofed in, and named the rope-walk. Here, under shelter, the work could go on all the year round, and machinery could be used. The simple whorl, with its single hook twining one thread or strand, became a wheel driving many whorls, each one giving work to a spinner. Then spinning machinery grew up outside, and came in to change the function of the ropemaker altogether, or at least in great part. Where first-class and special ropes were wanted, the old rope-walk was retained, and the spinner continued his old way; but alongside, another rope-walk was built, and on the middle path rails were laid, along which ran an automatic spinner, called a traveller, twining the threads into strands and the strands into ropes.

33. JUTE SLIVER

Where the old shed of the ropewalk stood, a new factory, filled with spinning machinery, now stands, and it also tends to grow. Add on to the twisting and reeling departments twining and balling machines, for they are merely adaptations of the same principles. Next, the steam engine, or the electric dynamo, having come as our motive power, we construct rope-laying machines, vertical and horizontal, in which the principle of the twister has been adopted on a large scale. As an adjunct to these, the closing machine, similar in construction, but simpler, is installed, and our rope and twine factory is complete.

Still extending our industry we add on a wing to the twine-spinning side, and therein instal machines for netting and plaiting, where fishing-nets and lacing bands of all kinds are made. On the rope-laying side we may build another wing, and form a wire-rope department. Provided we possess the capital, the wire-rope venture involves no difficulty. Our machines are simply hempen rope-laying machines, only heavier and stronger.

Principle of Rope-Spinning. Many an observant man has, no doubt, wondered for a moment at the firm consistency and solid structure of a rope. So far as one can see, there is no reason why the strands of a heavy cable should hold together. Weaving plaits weft and warp into unity; but the threads of the strands of the rope have been merely twined round each other by an impulse or force which must gradually lose its effect. According to rational expectation, we ought to find some day our rope slowly uncoiling and resolving itself into its original fibres. It is this tendency to uncoil which constitutes the unity of the cable.

Every effort those little fibres make to free themselves from each other binds them more tightly in the larger unity.

If we try to break up a cable by loosening the strands and threads, we have against us the natural effort of the fibres to free themselves. A cable dies, not because the natural force in the fibres has been too strong for man's art, but for the opposite reason—viz., that the fibres have ceased to struggle, have lost the power of resistance. That is why a new rope is stronger than an old one of the same quality.

Summary of this Course. Our study of textiles up to this point has been a broad review of the various trades engaged in it, and a consideration of the raw materials used, their sources of supply, and their cultivation. In our next issue we begin a study of fibre treatment- and proceed later to consider the manufacture of yarns, the processes of weaving, and special manufactures, such as felts, carpets, hosiery, and laces. Attention is given in its proper place to the preparation of artificial fibres, which constitutes one of the most marvellous applications of chemistry in modern industry. The concluding section is a comprehensive digest of the modern practice of dyeing, which seems every year to remodel itself and take advantage of the latest discoveries in synthetic chemistry.

AGENTS OF HUMAN EVOLUTION

Continued from page 778

Evidences of the Working of the Agencies of Evolution. Effects of Disease in Evolution. Immunity. Geological Evidence

By Dr. GERALD LEIGHTON

The Survival of the Fit. We may well believe that in the ages that are gone, when man was a primitive savage, the conditions which determined his survival were widely different from those acting upon the civilised man of to-day. The laws of their application were doubtless identical, the actual conditions different. Survival in those periods depended mainly upon physical strength and activity, great powers of bodily endurance, keenness of vision, and the other qualities which we associate with the life of the savage. Violence and privation were then active agents of selection, and those best able to withstand them survived.

But the case is different to-day. These conditions are no longer selective in civilised lands. The weakling, the stupid, or the blind, if born in a superior position, has a better chance of survival than many a stronger individual born to poverty. Selection along the old lines has ceased, the race is not necessarily to the swift nor the battle to the strong. But this does not mean that selection is no longer going on. Individuals do not, even now, all live to old age, or even to maturity. Immense numbers still perish both before maturity and during the time of their ability to have offspring. There is still a tremendously powerful agent of selection at work amongst civilised men, or amongst those who come into contact with him, and that agent is *infective disease*. In most countries infectious diseases are so prevalent that no individual escapes infection unless he be immune, nor death unless he has some degree of resistance.

The Causes from which Men Die. The only way in which we can find out the direction in which a species is evolving is to observe the characteristics of those individuals that perish, and compare them with those of the survivors. We thus discover the traits which determine survival.

This is the precise difficulty with plants and animals in nature. Their deaths may be due to any one of a number of causes acting upon some individual deficiency of which we are entirely ignorant. Most plants and animals are destroyed by some agency or other before maturity. Only a few, *even of the fit*, are allowed to survive. The majority of the deaths amongst them are probably haphazard. It was this fact which doubtless caused Lord Salisbury to deny the existence of natural selection.

But we know man much better than any other animal or plant. The peculiarities of every human being are, of necessity, noted before his death by some of his contemporaries. His offspring and descendants are also under close observation. For some thousands of years the chief causes of mortality among his races have been studied with anxious attention.

During recent years very precise scientific methods have been adopted. An army of trained and experienced medical workers has delved in almost every nook and cranny of the world, and in all civilised countries a Government department has tabulated the results of their labours. We know now precisely the causes from which men die, we know approximately the number of deaths due to each cause, and the average ages at which men die from this or that cause. We have, therefore, ample materials on which to found a judgment as to the effects produced on descendants, and, therefore, on the race, by these precisely ascertained and tabulated causes of elimination.

Haphazard Deaths Rare. "In the great majority of instances," says one writer, "men, especially civilised men, perish of disease. Haphazard deaths, comparatively speaking, are very rare. Moreover, where men live in dense and settled masses, and so can take disease from one another, the great majority of deaths are due to zymotic diseases—to diseases caused by minute living organisms.

"If ever natural selection has been at work, we should see its processes demonstrated by the familar causes of death among the living beings we know best. It is universally admitted that men differ greatly in their susceptibility to infection and in their powers of subsequent resistance. If, then, a lethal disease be very prevalent, it is evident that it presents a very stringent form of natural selection.

"In England, for example, hardly anyone escapes measles, whooping-cough, or tuberculosis, unless he be immune, or death unless he be resistant. Whenever any form of selection is stringent, it is accompanied by an evolution of those qualities which enable the survivors to escape. It follows, in the case of disease, that selection should cause an evolution of an inborn power of resisting infection, or of an inborn power of recovering from infection. The two qualities are quite distinct. They are also useful against quite distinct diseases."

The Two Kinds of Disease. We may regard diseases in this connection as of two kinds:

1. Those against which the patient can acquire some degree of immunity by recovery from an attack; for example, smallpox, measles, scarlet fever.

2. Those against which no power of resistance can be acquired by the individual.

Now apply the theory of natural selection of those individuals that are best fitted to survive, and observe the result. Note that though one attack of disease of the first kind usually confers individual immunity, yet in such cases the *race* never attains to immunity. Each succeeding generation remains susceptible as to infection as the preceding one. Thus Englishmen who, on recovery from measles, are individually immune, have offspring who are as susceptible to infection as were their parents.

Immunity. This happens in spite of the fact that individual Englishmen have acquired immunity from attacks of measles in childhood, and that this has gone on for generations. But measles is an agent of selection. It eliminates and weeds out those who cannot acquire immunity against it, and therefore the direction the evolution takes is towards an increase of the *power of acquiring* immunity. That is to say, those individuals which had inborn in them the greatest resisting power are the fittest to survive in that particular environment, and do survive, transmitting their inborn resistance to their descendants, the result being that the race increases its power of acquiring immunity against measles, which, therefore, in time becomes a comparatively trivial disease for that race.

But if measles be introduced into a new environment—for example, among a race such as the Polynesians, who have had no previous experience of it, amongst whom there has therefore been no selection of the fittest in this connection—what is the result? The disease may wipe out a whole tribe. There has been no opportunity for natural selection to evolve the power of acquiring immunity. For that reason, though Englishmen are as susceptible to infection by measles as Polynesians, they recover from it much more easily.

Consumption as a Factor in Evoluton. On the other hand, observe what has taken place with regard to those diseases against which the individual is unable to acquire a personal immunity, such as tuberculosis. Look again at the human race. For hundreds of years consumption has ravaged the Old World, and more especially the crowded parts of it, such as England. But Englishmen now increase in towns and crowded cities, the natural breeding-place of consumption.

Under similar conditions of life the natives of the New World, where until recently consumption was unknown, perish. When they are infected with consumption from white men they tend to extinction even in rural districts, not to mention in cities. Plainly there has been a great evolution, but as plainly it has resulted from the survival of the fittest by natural selection, and not from the transmission of any acquired characters.

There has been an inborn immunity evolved in this case as the result of long exposure to the selecting agency of the disease. So the Englishman has evolved his capacity to resist the infection of consumption and to gain the power of recovering from an attack of measles. The argument applies equally to animals other than man, and to agencies other than disease.

In the face of such facts as the foregoing it is impossible not to recognise the existence of the principle of natural selection, and we may proceed to note briefly other objections which have been brought forward against Darwinism.

The White Ruler of a Black People. The swamping effect of intercrossing has been regarded as one of the most formidable difficulties of the Darwinian theory. According to this objection, even where a very advantageous variation occurs in offspring, it would seem that this is just as likely to disappear in succeeding generations as to persist and be selected. It would tend to disappear as the result of intercrossing. It was urged that the same variation does not occur simultaneously in a number of individuals inhabiting the same area, which would be necessary in order that the variation might be handed on by heredity.

The difficulty is illustrated by the hypothetical case of a white man becoming the ruler of a black population, his whiteness representing the advantageous variation. As the result of his mating with a black woman his offspring would be yellow, and in course of time the variation would be swamped by intercrossing and the royal family would be black again.

This objection has been met by the supposition that the advantageous variation does occur in a sufficiently large number of individuals at the same time, and examples of this are given by Dr. Wallace in his work on "Darwinism," to which our readers are referred for further details on the point.

The Effects of Isolation. The importance of the isolation of a portion of a species in the process of organic evolution has been insisted upon by various writers, notably by Romanes. Isolation of those individuals who exhibited any special variation would undoubtedly preserve such a variation. Moreover, complete isolation involves the idea that new competitors as well as enemies are not a factor in the case, and, in the absence of these, intercrossing would be prevented. Isolation, to prevent the effects of intercrossing, is, of course, rigidly practised in artificial breeding by selection.

The point is, how far does the same factor operate in organic evolution in Nature? It happens in cases where any particular species reach oceanic islands and places where adaptation to new environments becomes a necessity. It is significant that such islands are very rich in distinct species. It is quite evident that some form of the isolation of new variations is a necessity for their persistence, otherwise they would be lost. But this isolation may be attained in other ways than geographically—for example, by physiological selection of individuals.

We still require more precise evidence in regard to the swamping effects of intercrossing where there is no isolation. All that is necessary here is to draw attention to this aspect of the evolution problem.

Darwin himself, in his "Origin of Species," admits that "isolation is of considerable importance in the production of new species," though he was, on the whole, "inclined to believe that largeness of area is of more importance."

There are other minor difficulties which have been advanced from time to time against the full acceptance of Darwinism, but they belong rather to the detailed study of the subject, and we must read the original writings of Darwin and Wallace to appreciate them. Indeed, those works should be read by every educated man. They are fascinating in themselves and epoch-making in their history.

The Evidence from Geology. Here, however, we must leave Darwinism for the present, and turn to a different aspect of organic evolution. From the present we turn to the past, from the living to the dead, from the story of the nations to the story of the rocks. In them also, if we read the signs aright, will be found precisely analogous evidence of the universal law of evolution in the world.

In the early part of this course we saw that, in order to gain a complete history of any species, it was necessary to study what is known of its distribution in the bygone ages. This aspect of biology is necessarily confined mainly to creatures which have or had a hard skeleton, which, though buried for many centuries, still is sufficiently preserved to indicate its structure. The study of the distribution of species from the point of view of time is termed *Palæontology*, and it is bound up with that of geology. In order, therefore, to fully appreciate this part of our task we must read also the section of this work dealing with geology.

The Story Told by Fossils. From what we have already learnt of the theory of organic evolution, we have come to the conclusion that animals have gradually become complex from more simple forms. We know that this complexity has not been an uninterrupted progress, but that, from various causes, animals have been extinguished from time to time, sometimes on a very large scale, and that they have also undergone degeneration in certain directions as well as progress.

The study of geology introduces us to extinct animals. Indeed, in some groups we find that there are more extinct species than existent ones. It is therefore to be expected that evidence of organic evolution will be abundant amongst fossil forms as well as in the species now inhabiting the globe. We may reasonably hope to find forms which, as it were, fill in the gaps between existing species and their remote ancestors, forms which may be regarded as connecting links between various species still existing, evidences of the actual variations which have been the stepping-stones to the modern forms of life.

To a certain extent the study of Palæontology satisfies these expectations. But many gaps still remain unfilled, and the connecting links in many cases are still to be found. Some urge this incompleteness as an argument against organic evolution, but, considering the comparatively short time which has elapsed since search has been systematically made in this direction, and the enormous area in the world open to investigation, the real wonder is the enormous mass of material which has already been collected.

Why the Record is Imperfect. A moment's thought will show us that a number of favourable conditions are necessary in order that the species of any given age may be adequately preserved. "In the first place, the animals to be preserved must not die a natural death by disease, or old age, or by being the prey of other animals, but must be destroyed by some accident which shall lead to their being embedded in the soil.

"They must be either carried away by floods, sink into bogs or quicksands, or be enveloped in the mud or ashes of a volcanic eruption; and when thus embedded they must remain undisturbed amid all the future changes of the earth's surface. But the chances against this are enormous, because denudation is always going on, and the rocks we now find at the earth's surface are only small fragments of those which were originally laid down. . . . In view of such destruction we are forced to conclude that our palæontological collections, rich though they may appear, are really but small and random samples, giving no adequate idea of the mighty series of organisms which have lived upon the earth.

"All that we have a right to expect is that, as we multiply the fossil forms in any group, the gaps that at first existed in that group shall become less wide and less numerous; and also that, in some cases, a tolerably direct series shall be found, by which the more specialised forms of the present day shall be connected with more generalised ancestral types. . . . Now, evidence of evolution of these varied kinds is what we do find, and almost every fresh discovery adds to their number and cogency." (Wallace.)

It would be quite beyond the scope and object of this course to enter into a minute description of the fossil forms of life; all we desire to do is to ascertain their bearing on the problem of organic evolution, and the kind of evidence they afford.

OILS. PAINTS. VARNISHES

Oils and Fats. Paints. Varnishes. Spirits. Distemper. Size. Wax. Resin. Turpentine. Pitch. Creosote. Paraffin. Benzine. Etc.

By Professor HENRY ADAMS

Oils and Fats. The term oil is a generic expression embracing the hard, solid, odourless waxes, tallows, and fats, the viscid fluid oils, the odorous essential oils, and the solid, fluid, and volatile hydrocarbons obtained in Nature or by destructive distillation.

The subject may be divided into three well-defined groups—the fixed oils and fats, the mineral oils, and the essential or volatile oils.

Fixed or Fatty Oils. *The fixed or fatty oils*, although varying considerably in external appearance, really form a distinct and homogeneous group of subtances having great similarity of chemical composition. As found in commerce, oils possess a faint, characteristic taste, a slight odour, and some colour, generally brownish-yellow. These characteristics, however, are due to certain impurities. In a really pure condition most oils have scarcely any characteristic taste, odour, colour, or physiological influence.

The ordinary method of separating vegetable oils and fats from nuts, seeds, etc., of which they form constituent parts, is by pressure, with or without the assistance of heat. They are also obtained by the agency of solvents, principally by the use of bisulphide of carbon and the light petroleum spirit, benzine, these being methods of production of comparatively recent introduction. Fixed oils are used very extensively in the manufacture of soaps and perfumery. Other purposes for which they are largely used are burning, lubricants, paints, varnishes, in the manufacture of linoleum, etc.

Linseed Oil. *Linseed oil* is a dark yellow to amber-coloured oil obtained by pressing the seeds of the flax plant. *Raw linseed oil* is produced by steaming the crushed linseed before removing the oil. *Boiled linseed oil*, which is darker and dries more quickly than raw oil, is produced by boiling the raw oil with litharge or a similar substance. It is commonly called simply *boiled oil*. Linseed oil is largely used in paints and varnishes, and also in the manufacture of linoleum, etc., The refuse after the oil is pressed out is in the form of slabs called *oilcake*, used for fattening cattle.

Olive Oil. *Olive oil* is a greenish-yellow fluid obtained by pressure from the fruit or pulp of the common olive tree, and may be divided into three kinds : (1) *Virgin oil*, which is the product of the first pressing without the application of heat, etc. ; (2) ordinary olive oil, or *sweet oil* which is obtained from the second pressing after subjecting the pulp to boiling water; and (3) *Pyrene oil*, which is a greatly inferior oil produced by a third pressing. Olive oil is extensively used in liniments, ointments, etc., in medical work, as a salad-dressing, and in cooking, while the poorer kinds are used for lubrication, illumination and soap-making.

Castor Oil. *Castor oil* is obtained from the seeds of the castor oil plant (*Ricinus communis*) by first passing them between rollers, and then, after placing in hempen bags, subjecting to pressure in a powerful press, which squeezes out the oil. This oil is afterwards raised to boiling point in order to separate the impurities. When purified it is used as an opening medicine. In its raw state it is sometimes used as a lubricant.

Cotton-seed Oil. *Cotton-seed oil* is the name given to the oil expressed from the seeds of the various cotton plants. The seeds are first separated from the fibre, and then crushed, the oil obtained closely resembling olive oil, as a substitute for which it is often used. Cotton cake, which is the substance left after the oil has been produced, is extensively used as a manure, and also as a food for cattle.

Palm Oil. *Palm oil* is a fatty oil obtained from various palm trees, chiefly from the fruit of the oil palm, of the West of Africa, by the tribes of which it is used for butter. It is employed for lubricating machinery, and also in the manufacture of candles, soap, etc.

Rape Oil. *Rape oil*, also called *colza oil* and *rape seed oil*, is a thick, yellowish oil obtained from the seed of the rape plant. It is chiefly used for lubrication and in the manufacture of indiarubber, and, to a limited extent, for illumination.

Cocoa-nut Oil. *Cocoa-nut oil* is a white, solid substance obtained from the cocoa-nut palm, and when subjected to pressure, is divided into two parts, one liquid and the other solid, the latter being known as cocoa stearin and used largely in the manufacture of candles. Cocoa-nut oil is also used in making marine soap, which lathers in sea water.

Tallow. *Tallow* is an animal fat derived mainly from sheep and oxen, and consists chiefly of stearin, palmitin, and olein. The tallow known to commerce is nearly always of a yellow colour, but animal tallow, when pure, is white. Commercial tallow is divided into several kinds, the best of which are used for candle-making, while the inferior qualities are used in the manufacture of soap, for dressing leather, and similar purposes. The purest is known as Russian tallow.

Margarine. *Margarine* is a substance extracted from hog's lard, and also from the fatty matter of various vegetable oils, the better qualities of margarine being obtained from olive oil, and consisting of stearin and palmitin. It is used for a substitute for, or an adulterant of, butter. *Pure butter* is produced by the churning of cow's milk.

Lard Oil. *Lard oil* is a colourless oil obtained from hogs' lard. It is used for lubrication and burning, for adulterating sperm and other oils, and in some places, especially the United States, for the manufacture of soap.

Sperm Oil. *Sperm oil*, which is an abbreviation of spermaceti oil, is, as its name implies, obtained from the spermaceti or sperm whale. It is used as train-oil, but not so extensively as the oil obtained from the common whale, which is known as *whale oil*. Sperm oil is also used as a lubricant.

Mineral Oils. *Mineral oils* are mixtures of hydrocarbons which are obtained directly from mineral sources, thus differing from the essential and fatty oils which are of vegetable and animal origin. *Petroleum* is the real mineral oil, and it is from this that the other oils are derived as described further on.

Essential Oils. *The essential or volatile oils* constitute a very extensive class, which possess, in a concentrated form, the odour characteristic of the plants or vegetable substances whence they are obtained. They are for the most part insoluble in water, or soluble only sparingly and with difficulty; but in alcohol, ether, fatty oils, and mineral oils, they dissolve freely. In many important respects they differ from the fatty oils; they are not oleaginous to the touch, and make no permanent grease spot, they have an aromatic smell and a hot, burning taste, and in chemical constitution they present no relationship to the fats and oils.

Essential oils have a wide range of uses, of which the principal is in perfumery. The value of flavouring herbs, condiments and spices is due in large measure to these oils which they contain, and further the commercial value of tea, coffee, wine, and other beverages is largely dependent on the delicate aroma which they owe to minute quantities of such oils. For the flavouring of liqueurs, aerated beverages and other drinks essential oils are used, and their employment is not less important in the manufacture of confectionery and in the preparation of many dietetic articles. In the arts the cheaper oils, such as oil of turpentine, are used in the manufacture of varnishes, and oils of turpentine, lavender, and spike are used as vehicles for painting, more particularly for the painting of pottery and glass.

An *emulsion* is a mixture of liquids where one is suspended in the other in the form of globules, both liquids being insoluble in each other, as, for instance, oil and water. It may also be a mixture in which a liquid contains solid particles in suspension—as, for example, camphor emulsion.

Wax. *Wax* is a solid, fatty substance of animal and vegetable origin, allied both in sources and constitution to the fixed oils and fats, from which it differs principally in its greater hardness and higher melting-point. Of wax from animal sources there are in commerce beeswax, which is by far the finest, Chinese insect wax, and spermaceti. The more important vegetable waxes are Japanese wax, myrtle-berry wax, carnauba wax, and palm wax.

Beeswax. *Beeswax* is secreted by all honey bees, and by them formed into the cell walls and other parts of their comb. It is separated by draining the honey, melting the drained comb in boiling water, and collecting the wax which solidifies on the top as the water cools. In this state it is formed into cakes of raw or yellow wax, good examples of which are of a light yellow colour, translucent, with a faint odour of honey.

The uses of beeswax are multifarious, but it is most largely consumed in making candles for the religious services of the Roman Catholic and Orthodox Greek Christians, and for wax figures and models.

Chinese Insect Wax. This wax is a secretion deposited by an insect on the twigs of a species of ash. The wax is, in its origin, etc., closely related to the lac produced by the allied species of *coccus*. When separated from the twigs, which it encrusts, and purified, it is a hard, translucent, white, crystalline body, similar to spermaceti, and in composition consists of *cerin*, one of the constituents of beeswax. It is little known in Europe, but forms an important trade in China and Japan, where it is largely used for candle-making and for medicinal purposes.

Japanese Wax. *Japanese wax* is a hard, wax-like fat, obtained from the small stone fruits of several species of *rhus* cultivated in Japan. It is not a true wax, but consists principally of the glycerine palmitin with small proportions of stearin and disseminated crystals of free palmitic acid. It is largely mixed with, and used as a substitute for, beeswax, except for uses where its rancidity renders it objectionable.

Myrtle-berry Wax. This is obtained from the fruit of several species of *myrica*, in the United States, New Granada, Venezuela, the Cape of Good Hope, etc. It is a hard, greenish substance, with a pleasant, balsamic odour, and consists principally of free palmitic acid with a little stearic acid and myristic acid. It is consumed principally in the United States in combination with beeswax for candles.

Carnauba Wax. Carnauba wax is an exudation on the surface of the growing leaves of the carnauba palm of tropical South America. The wax is obtained by cutting off and drying the young leaves, from which it is then shaken as fine dust, and caked by melting either over an open fire or in boiling water. It is a substance of considerable commercial importance in Brazil, whence large quantities are sent to Europe for use in the candle trade and otherwise, as a substitute for beeswax.

Palm-tree Wax. *Palm-tree wax* is an exudation formed on the stems of certain South American palms. As scraped from the trees and compacted by melting, it is a mixture of resin and wax. The pure wax, which is used for candles, may be separated by digesting with boiling spirit. This wax is little seen in European commerce

Spermaceti. *Spermaceti* is a solid, waxy body found in special cavities in the head of the sperm whale, where it is held in solution by sperm oil while the creature is alive. Spermaceti candles of definite size are employed as a standard for illuminants on account of the uniform, steady light they afford. The substance is further used in the dressing of fabrics, and in medicine and surgery.

Resin. *Resin* is a secretion formed in special resin channels or passages of plants, from many of which, such as coniferous trees, it exudes in soft tears, hardening into solid masses in the air. It is also obtained by making incisions in the bark or wood of the secreting plant. Certain resins are obtained in a fossilised condition, *amber* being the most notable instance of this class, and *African copal* and the *kauri gum* of New Zealand are also procured in a semi-fossil condition. The resins which are obtained as natural exudations are in general compound bodies containing more than one simple resin and varying proportions of essential oil. These compounds, when soft, are known as *oleo-resins*, and when imperfectly fluid, they are called *balsams*. Other resinous products are, in their natural condition, mixed with gum or mucilaginous substances, and known as gum-resins. A typical resin is a transparent or translucent mass, with a vitreous fracture and a faintly yellow or brown colour, inodorous, or having only a slight turpentine odour and taste. A series of gradations among resins may be traced from the hard, glassy, transparent copals through soft elemis and oleo-resins, semi-fluid balsams, and fluid wood oils, to the most limpid essential oils. The hard, transparent resins are used principally for varnishes and cement, while the softer, odoriferous oleo-resins and gum-resins, containing essntial oils, are more largely used for pharmaceutical purposes and incense.

Amber. *Amber* is a fossilised resin, of a pale yellow to reddish colour, the product of extinct varieties of pine trees which formerly grew where the Baltic Sea is situated, and by the waves of which the amber is now cast upon the surrounding shores, more especially on the Prussian coast. It is used chiefly for making beads, brooches, and the mouthpieces of pipes, and when heated with nut oil and thinned with turpentine, forms amber varnish.

Copal. *Copal* is a hard, lustrous, amber-like resin, which, when dissolved in turpentine or alcohol, forms one of the most valuable varnishes. There are many varieties, as Madagascar copal, Sierra Leone copal, South American copal, etc., but by far the most important—from a commercial point of view—is Zanzibar, or East African copal. It is found in two distinct conditions: the first, raw or recent, called *chakaze*, corrupted to "jackass copal;" the second, the true, or ripe copal. The raw copal is obtained direct from the trees or at the roots, and is not used in European commerce. The true, or fossil, copal is found embedded in the earth to a depth of three or four feet in places where not a tree is to be seen.

Canada Balsam. *Canada balsam* is a colourless resin, secreted in the form of a liquid under the bark of the balsam fir tree of North America, from which it is obtained by puncturing the bark. It thickens with age, and is used in making varnishes, but as it remains transparent permanently, it is chiefly used for mounting small objects for use under the microscope.

Turpentine. *Turpentine* consists of the oleo-resins which exude from certain trees, especially from some conifers, and from the terebinth tree (*Pistacia Terebinthus*). It was to the product of the latter, now known as *Chian turpentine*, that the term was first applied. Chian turpentine is a tenacious, semi-fluid, transparent body, yellow to dull brown in colour, with an agreeable, resinous odour and little taste, and on exposure to the air it becomes dry, hard, and brittle. In their general characters, turpentines are soft solids or semi-fluid bodies, consisting of a mixture of one or more resins with essential oils.

Oil or spirit of turpentine, pine oil, or turps, as a commercial product, is obtained from all or any of these oleo-resins, but on a large scale only from crude or common turpentine. The essential oil is rectified by distillation with water and alkaline carbonates, and the water which the oil carries over with it is removed by a further distillation over calcium chloride. Oil of turpentine is a colourless liquid of oily consistency, with a strong odour and hot, disagreeable taste. On exposure to the air it dries to a solid resin, and when oxidised in the presence of water, gives off peroxide of hydrogen, which is utilised in the preparation of the disinfectant called "Sanitas." Oil of turpentine is largely used in the preparation of varnishes, and as a medium by painters for their "flat" colours.

Rosin, resin, or colophony, is the residue left behind after the oil of turpentine has been distilled off from crude turpentine. It varies in colour from white to dark brown, according to the purity, the age of the tree, and the heat used in the preparation. It is used as a flux for solder, for rubbing on violin-bows, for combining with tallow in candle-making, also in inferior varnishes and sealing wax, as well as in the manufacture of the common yellow soap.

Alcohol. *Alcohol* is a volatile organic body, constantly formed during the fermentation of vegetable juices containing sugar in solution. It is extracted from spirituous liquors of different kinds by successive distillations. The alcohol, being more volatile than water, gradually accumulates in the first portion of each distillate. After a few operations, the spirit obtained is as strong as it can be made by this process, and further repetition does not separate more water from it. In commerce, the strongest spirit is known as spirit of wine, and contains about 90 per cent. of alcohol. The remaining 10 per cent. of water must be removed by some chemical agent that will combine with water and retain it at the boiling point of the spirit, and be without any specific action on the alcohol. Lime is generally used for making the absolute alcohol of commerce. For this purpose the caustic lime is broken into pieces about the size of a walnut and placed in a retort, spirits of wine is now poured into the vessel, just sufficient to cover the lime, and the whole is left for a night, during which time the lime gradually slakes from the absorption of water, and the anhydrous alcohol is left to distil off.

Absolute or *pure alcohol* is a colourless liquid, of a pleasant smell and acid, burning taste, with a specific gravity of 0·794. It mixes with water in all proportions, is a solvent for organic principles, bases, resins, oils, etc., and as such has an extensive use in the arts and in medicine. Different grades of alcohol are sometimes designated in trade according to the source from which they are derived, as *grain alcohol*, prepared from maize or other grain; *root alcohol*, from potatoes and beets, and *moss alcohol*, which is made in large quantities in Russia, Norway, and Sweden. *Proof spirit* contains 49·3 per cent. by weight, or 57·1 per cent. by volume of pure alcohol; *overproof* and *underproof* are designations of a stronger and weaker solution respectively. Distilled liquors or ardent spirits, such as whisky, brandy, and gin, contain 40 to 50 per cent. of absolute alcohol, wines from 7 to 20, porter and ale from 5 to 7, and beer from 2 to 10 per cent.

Methylated Spirit is a mixture of ordinary spirit of wine or alcohol, with one-ninth of its volume of wood-naphtha (*methylic alcohol*). The naphtha communicates a disagreeable flavour which renders the spirit unfit for drinking. It is of much use in the arts as a solvent, for preserving specimens, in the manufacture of varnishes, for burning in spirit lamps, etc.

Lac. *Seed-lac* is obtained from *stick lac*, which is the name given to the resin-covered twigs of various trees of Southern Asia, by removing the resinous substance from the twigs and grinding to a fine powder in water, which dissolves the greater part of the colouring matter, leaving the granular residue which, after drying, is the seed-lac.

Shellac is seed-lac melted, strained through thick canvas, and formed into thin layers or plates. Shellac, which varies in colour from a dark amber to an almost pure black appearance, may be bleached by dissolving in a boiling lye of caustic potash and passing chlorine through the solution till all the resin is precipitated. Lac is a principal ingredient in sealing wax, and forms the basis of some of the most valuable varnishes, besides being useful in various cements. Though lac is to be found everywhere, British imports are almost entirely drawn from Calcutta, which derives its supply chiefly from the hills of Chutiá Nágpur, but also to a less degree from Assam and Mirzápur in the North-Western Provinces.

French Polish. *French polish* is a liquid used for polishing wood, prepared by dissolving shellac and a little colouring matter in methylated spirits of wine. It is applied with a sponge or rag, and the surface is then rubbed very thoroughly with a soft pad, sticking being prevented by an occasional touch of linseed oil on another rag. The operation is usually repeated two or three times, to prevent the grain of the wood from rising thorugh the polish. *Glazing* is a cheap imitation of French polishing put on as a varnish.

Varnish. *Varnish* is a fluid preparation which, when spread out in thin layers, dries either by evaporation or by chemical action into a hard, transparent and glossy film. The materials which form almost exclusively the permanent body of varnishes are the drying oils and resinous substances, the chief of which are the copals, lac, dammar, elemi, amber, mastic, sandarac and resin. For certain forms of varnish the drying oils themselves act as the solvent for the resin, but in other cases volatile solvents are employed, those chiefly used are methylated spirit, wood spirit, ether, benzine, turpentine and other essential oils.

According to the solvent employed, the ordinary kinds of varnish are divided into three classes—(1) spirit varnishes, (2) turpentine varnishes, (3) oil varnishes.

Spirit Varnishes. *Spirit varnishes* dry with great rapidity owing to the volatilisation of the solvent spirit, leaving a coating of pure resin of great hardness and brilliance, but the film is deficient in tenacity, cracking and scaling readily on exposure. The resin lac, either as grain, shell or bleached lac, is the basis of most spirit varnishes, but sandarac is also used largely, and to these are added, in varying proportions, the softer resins elemi, Venice turpentine, mastic, etc., which give elasticity and tenacity to the varnish. The solvent is almost exclusively methylated spirit. Spirit varnishes are used principally for cabinet work and turnery, stationery, gilding and metal-work.

Turpentine Varnishes. Turpentine is the solvent principally used for making dammar varnish, the solution being effected by powdering the resin and boiling it with a proportion of spirit of turpentine, after which more turpentine is added in the cold state to bring the preparation to a proper consistency. Turpentine varnishes are also made in which the principal resinous bodies are sandarac and common resin, and, moreover, turpentine is largely employed to reduce the consistency and to improve the drying properties of copal varnish.

Oil or Fatty Varnishes. In these the basis or solvent consists principally of linseed oil, but the other drying oils—poppy and walnut—may also be used. It is in the form of boiled oil, or of oil prepared with driers, that these oils are used in varnish making. The resin principally used in oil varnishes is copal, and its varieties differ very much in hardness—that is, in the temperature at which they melt and distil.

Paints. *Paints* may be divided under several heads, according to the chief ingredient or base which is mixed with the vehicle or medium, or carrier—such as lead paints, oxide paints, zinc and baryta paints, graphite paints, etc. Generally speaking, lead paints are used upon woodwork, oxide of iron and graphite paints upon ironwork, zinc and baryta paints upon surfaces exposed to the impure air of towns, where white or delicate tints require to be preserved from the sulphur impurities which turn lead paints black. Besides the base and vehicle, it is generally necessary to add a *drier* to oxidise the vehicle rapidly and cause it to dry quickly, and a *solvent* to dilute the vehicle so that it will flow readily from the brush, besides the *pigment* for giving the required colour.

Lead Paints. *White lead* is a mixture of hydrated oxide and carbonate of lead in proportions of approximately 25 per cent. of the former and 75 per cent. of the latter. The Dutch method of manufacture is a long process, but is briefly as follows: Metallic lead, in the form of discs called "buckles" or open cast grids, is laid on earthenware pans containing vinegar, which are afterwards piled into bins, covered over, and left for about three months. During this time the temperature rises and a complex chemical change takes place by which the buckles are converted into white carbonate. The white lead is ground to a fine powder and mixed with 10 per cent. of linseed oil, forming the paint known as white lead in oil.

Red lead, or minium, is a pigment made by exposing litharge or massicot to air at a very high temperature, under which conditions it absorbs more oxygen. When mixed with linseed oil and mastic it is used as a cement; but it is used chiefly as a pigment, for the reason that when mixed with either linseed oil or water it forms a good first coat owing to its great covering powers.

White Lead paint is not only poisonous, but it rapidly blackens in the presence of the sulphurous fumes which are present in the air of all towns. On the coast, where it is subject to the action of the sea air, it is liable to "chalk off," that is, rub off with the hand as if the wood had been chalked.

Zinc Paints. *Pure zinc oxide paint*, ground in pure, refined, boiled linseed oil, furnishes a permanent white with great covering power, without requiring the addition of driers, but it is necessary to ensure that it is *zinc oxide*, and not merely *Charlton white*. Being a pure white, it permits of mixing to delicate shades of colour which the yellowish tinge of white lead will not allow. It is non-poisonous, and not acted upon by sulphuretted hydrogen. The largest manufacturers of zinc white are the Vielle Montagne Company of Jenappe, Belgium, who turn out about 12,000 tons per annum.

Charlton white or *lithopone* is composed of zinc sulphide and barium sulphate. It is sometimes used as a substitute for white lead paint for inside use, as it has greater covering power and keeps its colour better, but it does not give so hard or permanent a surface.

Iron Oxide Paint. *Iron oxide paint* has, as the base, a magnetic oxide or sesquioxide of iron prepared from hæmatite ore. It has been used for many years as preferable to lead paints for painting ironwork, but is now giving way to graphite paints, which experience shows to be more lasting.

Graphite. *Graphite*, or *black lead*, is one of the forms in which carbon occurs in Nature, and it receives its name from its use in the manufacture of writing pencils. Besides pencils, it is used for burnishing iron to prevent rust, and also for placing between rubbing surfaces of machinery to prevent friction. The best quality of graphite used for pencil making is obtained chiefly from Siberia, while the coarser varieties, from Ceylon and elsewhere, are used for stove polish and lubrication.

Graphite paint is a mixture of graphite with pure linseed oil. It is the best preservative among the oil paints for surfaces of iron and steel.

Metallic Paints. There are several varieties of these for giving lustrous surfaces, such as bronze, gold, silver, etc. The most recent is "Lustrogen," an aluminium paint, which is said to retain its brilliancy indefinitely, and to have a covering capacity of 900 to 1,000 square feet to the gallon. It resists sewer gas, sea-air, sulphuretted hydrogen, damp, and heat, and is suitable for stable fittings and all ornamental ironwork.

Enamel paints consist almost entirely of zinc oxide mixed with a varnish and the necessary colouring materials. It is the zinc white which gives these paints their peculiar durability.

Fire-resisting paints contain soluble glass in their composition. For example, a good white paint is made with finely ground zinc white (*oxide of zinc*) mixed with a solution of soluble glass (*silicate of soda*), with a strength of 40 to 45 degrees of the Beaumé hydrometer, until it has attained the consistency of ordinary paint.

Cyanite is a colourless preparation put on as a paint, for preventing wood from flaming when exposed to fire.

Fire-resisting putty is made of soluble glass (*silicate of soda*) mixed with ground chalk, and hardens within six or eight hours. It may be coloured with sulphide of antimony, iron filings, or zinc filings, incorporated with chalk.

Polishers' putty, or putty powder, is powdered oxide of tin, used for polishing glass, granite, and other hard substances.

Water Paints. Certain washable paints or distempers are known by this name, such as *Duresco*, made by the Silicate Paint Co., of Charlton; *Olsina*, by Mander Brothers, of Wolverhampton; *Hall's Sanitary Washable Distemper*, by Sissons Brothers & Co., Ltd., of Hull; *Magnite Sanitary Water Paint*, by Clemons, Marshall & Carbert, of Leeds; and *Mayresco*, by Mayfield Brothers, of Sulcoates, Hull.

Luminous Paint. Balmain's luminous paint is made by heating a mixture of sulphur and powdered oyster-shells in a closed crucible, forming a polysulphide of calcium, which is then mixed with mastic varnish. It is used for clock dials, lanterns for powder magazines, etc., owing to its peculiar property of emitting light, in darkness, without a flame; also for keyhole escutcheons, match boxes, and other small articles requiring to be seen in the dark. It is generally painted over the under side of a sheet of glass to protect it from being rubbed off.

Size. *Size* is a substance of a gelatinous nature, like weak glue. The best is made from leather parings, parchments, etc., boiled in water and afterwards purified. For common purposes, it is made from potatoes, glue, or scraps of horns, hides, etc., and is used for preparing writing-paper, and also by painters for stopping the pores of the material to which it is applied to reduce its absorbent power. It may be rendered less liable to putrefaction by adding one-tenth of a pound of boracic acid to each gallon of liquid size, or a little carbolic acid will effect the same purpose. The smell may be rendered less objectionable by the addition of a little oil of cloves or essence of peppermint. *Sichel-glue* is a non-odorous size which dissolves in cold water.

Pumice-stone. *Pumice-stone*, or *pumice*, is a light, spongy mineral substance, formed by the solidification of the foam on molten lava due to the escape of gas or steam. It is generally of a whitish-grey colour, and consists of about 70 per cent. silica, 20 per cent. alumina, and 10 per cent. soda, potash, and iron oxide. It is extensively used as a smoothing material for ivory, horn, wood, paint, marble, and various metals. It is much used by house-painters for rubbing down the various coats of paint work. For some purposes it is ground to a powder and used in a similar manner to emery paper.

Artificial pumice is made from a mixture of calcined and crushed quartz and alumina, moulded up into the form of bricks.

Sal-ammoniac. *Sal-ammoniac* is the earliest known salt of ammonia, and is now called ammonium chloride. It was first manufactured in Egypt, and for many years Europe was supplied with it from that country. It occurs usually in the form of a hard, white cake, opaque, or only slightly translucent, with a cooling and rather disagreeable taste. The first attempt to manufacture sal-ammoniac in Europe was made in London about the beginning of the eighteenth century; but the first successful manufacture in this country was established in Edinburgh about the year 1760.

Spirits of Salt. *Spirits of salt*, known also as *hydrochloric acid, muriatic acid*, or *hydrogen chloride*, is a colourless, strongly acid solution, made by dissolving hydrogen chloride gas (*hydrochloric acid gas*) in water. It is extensively used in the arts. When *killed* by the insertion of scraps of zinc, it is used by tinmen as a soldering fluid in conjunction with sal-ammoniac.

Blue Stone. *Blue stone*, or *Roman vitriol*, or more correctly *sulphate of copper*, is prepared on a large scale direct from the cementation water from pyrites mines, by evaporation to the crystallising point. It is also prepared by the oxidation of sulphide of copper in a furnace at a comparatively low heat, and by the direct action of sulphuric acid on metallic copper, as well as by various other processes. Sulphate of copper is very largely used as a basis for the preparation of other copper compounds, in electro-metallurgy, calico printing, and in the American method of extracting silver from its ores. It is also used in the preparation of the copper pigments, Scheele's green, Schweinfurt green, and Paris green. A solution of sulphate of copper is considered to be the best curative for dry rot in timber, put on as a paint, if the fungus has not obtained too firm a hold.

Copperas. *Green vitriol, ferrous sulphate*, or *copperas*, is a salt of iron, of a bluish-green colour and an astringent, inky, and sweetish taste. Copperas is manufactured, with alum, by the oxidation of the iron-pyrites contained in aluminous schists, such as those of the coal-measures of Renfrew and Lanark. It may also be prepared by Spence's method of heating ground puddling-furnace slag, tap-cinder, or Cleveland ironstone with sulphuric acid. Copperas is used in dyeing and tanning, in the manufacture of ink, Prussian blue, and Nordhausen sulphuric acid or fuming oil of vitriol, in medicine as an astringent and tonic, and in analytical chemistry.

Ink. *Ink* is a thin fluid used for writing and drawing, and also a thicker substance used in printing, being distinguished under the titles of *writing ink* and *printing ink*.

Common black writing ink is mostly made by steeping a mixture of galls, copperas, and gum-arabic, while the colouring matter is gallotannate of iron, and sometimes a little logwood is added to improve the colour.

Printing ink is a mixture of boiled oil and the colouring pigment. When the ink is required to be fine, nut and other fine oil is used, sometimes mixed with a little resin; but for the coarser inks resin only is used. The pigment for black inks is generally lampblack, while, to improve the impression, soap is also added.

There are also many other varieties of ink, as: India, China or Indian ink, book ink, copying ink, marking ink, lithographic ink, etc.

SHORTHAND

Seventh Instalment of the Special Course of Shorthand Taught by Messrs. Pitman & Sons on their Twentieth Century Plan

By SIR ISAAC PITMAN & SONS

TWO highly important abbreviating principles are introduced to the student's notice in this instalment, namely the expression of additional consonants either by halving or doubling the length of any consonant.

The Halving Principle. Light consonants are made half their usual length to indicate the addition of *t*; thus

ache, *ached*, *sect*, *Kay*, *Kate*, *skate*,

pay, *pate*, *plate*, *prate*, *pout*, *bowl*,

bolt, *bolts*, *bullet*, *mow*, *moat*.

Heavy consonants are made half their usual length to indicate the addition of *d*; thus

ebb, *ebbed*, *bow*, *bowed*, *guy*, *guide*,

guided, *glide*, *Gride*, *grey*, *grade*,

grades, *live*, *lived*, *livid*, *ease*, *cased*.

It will be noticed from the foregoing examples that a vowel coming before a half-length character is read first, the same as before a full-length consonant; as

oft, *act*.

A vowel coming after a half-length consonant is read NEXT to the primary letter; thus

tie, *tight*, *no*, *note*.

When a consonant is hooked *finally*, it may be halved to express the addition of EITHER *t* OR *d*; thus *paint* or *pained*; *plant* or *planned*; *tint* or *tinned*; *tents* or *tends*; *vent* or *vend*; *mounts* or *mounds*; *rent* or *rend*; *puffed*, *paved*.

In words of *more than one syllable*, with certain exceptions, a letter may be halved to express the addition of EITHER *t* OR *d*; thus

between, *Bedwin*, *rabbit*, *rabid*, *credit*,

crowded, *collaret*, *coloured*, *disappoint*,

despond, *backward*,

forward (*wd* contraction for *-ward*);

dockyard (*yd* contraction for *-yard*);

seated, *suited*, *stated*.

The four consonants in addition to being halved to express the addition of *t*, are also halved and thickened to represent the addition of *d*; thus

mate, *made*, *aimed*, *mode*, *tempt*,

timid, *deemed*, *neat*, *need*, *sent*, *send*,

felt, *felled*, *heart*, *hard*, *moored*.

The forms *ld* and *rd* are, however, used only when these consonants immediately succeed each other, as

paled, *paired*, *mailed*, *marred*.

When a vowel comes between *l-d*, or *r-d*, these consonants must be written in full; thus

pallid, *parade*, *mellowed*, *married*.

Lt is written upward; as belt, except after *n*, *ng*, *w*, *kw*, when it is written downward, as

knelt, *ringlet*, *dwelt*, *quilt*.

The consonants *mp*, *ng*, cannot be halved to express the addition of either *t* or *d*, unless they are hooked, initially or finally; thus

impugn, *impugned*, *impend*, *slumbered*,

rampart, *anger*, *angered* or *anchored*.

The double consonants *lr*, *rr*, cannot be halved for the addition of *t* or *d* under any circumstances. The heavy half-length signs are allotted to *md*, *nd*, *ld*, and *rd*.

Exercise.

1 Pet, pit, Tate, taught, kit, aft, east, shot.
2 Wit, await, light, alight, yet, plot, crate.
3 Bed, aided, edged, jade, goad, egged, mead.
4 Old, erred, blade, bread, glade, broad, dread.
5 Pound, fined, accident, inward, brickyard.
6 Meat, mud, night, Ned, admit, doomed, fillet, failed.
7 Bailed, ballad; showered, charade; tarred, tirade.
8 Pelt, polite, kilt, melt, omelet, inlet, runlet.
9 Impound, dampened, lingered, hungered.

The upward *h* must be written in words that contain *h* halved, with or without final circle or hook, as

hat, hats, heat, hunt, hints,

haft, heaved.

After the *-tion* hook, the stroke *st* may be written upward when it cannot be written downward; thus

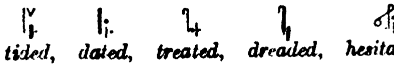
excursionist, liberationist, salvationist.

The half-length *r* [/] should never be written alone, nor with *s* only [ ] added. Write [not] *rate,* [not] *write,* [not] *writes.* It should generally be used finally for *rt,* and for *rd,* when it is not convenient to write ; thus

dart, fort, lard.

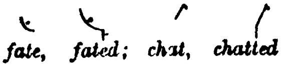
Two half-length strokes, or two strokes of unequal length, must not be joined together UNLESS THEY MAKE AN ANGLE; thus / *cht* must not be joined to / *cht* for *chit-chat;* nor *pr* to \ *pt* in *propped;* nor — *k* to – *kt* in *tactics,* nor ⌒ *m* to ◡ *nt* for *minute.* Detach the signs, or write the letters in full; thus or  *chit-chat,*  *propped,*  *tactics,* *minute.* In *ford,* *named,* etc., the junction, being evident, is allowed.

Half-sized *t* or *d* immediately following the consonants *t* or *d* is always disjoined; thus



tided, dated, treated, dreaded, hesitated.

Verbs written with the half-length principle form their past tense thus



fate, fated; chat, chatted;

nod, nodded; part, parted.

Verbs written by a half-length letter ending with a hook form their past tense thus *print,*  *printed,* *plant,*  (to preserve the straightness of the stroke) *planted,* *stint,* *stinted,* *acquaint,* *acquainted,* *grant,*  *granted,* *rant,*  *ranted.*

When a word ends with *t* or *d* followed by a vowel, the letter must be written in full, and not indicated by the halving principle; thus

guilt, guilty; dirt, dirty; loft, lofty;

fault, faulty; mould, mouldy.

The circle *s*, as already explained, is always read *last* when it is written at the end of a word; thus

pun, punt, punts; join, joint, joints;

frown, front, fronts.

Exercise.

1 Hate, height, hit, hits, huffed, hounds.
2 Fashionist, elocutionist; evolutionist, revolutionist.
3 Wrote, writ, write, rout, port, tart, lured.
4 Pit-a-pat, bribed, tick tack, emanate, numbed.
5 Attitude, audited, vegetated, obtruded.
6 Fitted, potted, jotted, netted, rooted, pirated.
7 Branded, grounded, stunted, unacquainted.
8 Fort, forty; malt, malty; neat, natty; loved, love-day.
9 Tin, tint, tints; pine, pint, pints; shunt, shunts.

Grammalogues. The following additional grammalogues should be memorized:

call-d(¹), *cannot*(¹), *could, great, not*(¹),

short(¹), *told, toward, that*(¹), *without.*

The Double-Length Principle. Curved consonants are made twice their usual length to indicate the addition of *tr, dr,* or *thr*; thus

flow, floater, laugh, laughter, father,

vain, vendor, thunder, oyster, shatter,

mother, smoother, centre or *sender, lighter,*

slighter, builder, border.

When *dr* or *thr* follow an initial *l*, they are expressed by and not by doubling the *l*; thus

older, leader, leather.

After *f, sh, m* also, *dr* is expressed by and not by doubling; thus

fodder, shudder, Modder.

Straight consonants hooked finally, or which follow *another stroke*, are made twice their usual length to indicate the addition of *tr* or *dr*; thus

pain, painter, ten, tender, wren, render,

won, wonder, yon, yonder, Hun, hunter,

rafter, neck, nectar, rector, detractor,

disputer, debater.

The character *mp* is doubled to express *mpr* or *mbr*; thus

temper, chamber.

The character *ng* is doubled to express *ngkr* or *nggr*; thus

shrinker, longer.

The hooked consonants *mpr, mbr,*  *ngkr, nggr* are generally more convenient for verbs, because they can be readily halved for the past tense; thus

scamper, scampered, cumber, cumbered,

canker, cankered, linger, lingered.

In a few common words, it is allowable to double a letter to express the addition of the syllable *-ture*; thus

feature, future, signature, picture.

When the present tense of a verb is written with the double-length principle, the past tense is written with the half-length principle; thus

ponder, pondered, tender, tendered,

encounter, encountered, slander, slandered,

hinder, hindered, pamper, pampered.

When a word ends with a vowel preceded by *tr, dr*, or thr, these consonants must be *written* and not indicated by doubling; thus

flatter, flattery, winter, wintry,

sunder, sundry, feather, feathery.

The circle *s* at the end of a double-length character is read *last*, as usual; thus

tenders, feathers, counters.

EXERCISE.

1 Enter, Easter, loiter, shutter, matter.
2 Founder, asunder, smatter, cylinder, Walter.
3 Palter, porter, folder, charter, chartered.
4 Letter, louder; latter, ladder; fetter, feeder.
5 Shouter, shedder; mutter, madder; fitter, federal.
6 Pointer, tinder, ranter, wander, wandered.
7 Elector, gunpowder, dissector, pretender.
8 Vamper, Humber, jumper, timber, belonger.
9 Slumber, slumbered; anger, angered.
10 Flounder, floundered; director, directory.

KEY TO EXERCISES IN LAST LESSON.

1 Quibble, quiet, quarter, quarrel, require, guano, languish.
2 Weal, wallow, wealth, Wells, wheel, whelm, meanwhile. wheeler.
3 Fuller, roller, skuller, poorer, admirer, borer, snorer.
4 Pump, jump, embellish, ambitions, whack, whip, whisper.

1 
2 
3 
4 
1 Hock, haggis, hod, hoary, haddock.
2 Hive, haggle, hairy, cohesion, unhinge.
3 Hilly, horror, hump, happily, handy.

MORE ELEMENTS IN DETAIL

Bleaching Powder. Calcium. Metallic Elements, including Aluminium, Magnesium, Manganese, Iron, and Zinc

Continued from page 844

By Dr. C. W. SALEEBY

Bleaching Powder. Bleaching powder is another very important substance which contains calcium, though this is really not the most important element in its composition. It is prepared by the action of chlorine—its active ingredient—on calcium hydrate, or slaked lime. This last, prepared with great care and free from impurity, is spread out in thin layers over the floor of stone chambers, and then chlorine gas is passed over it. The compound that is formed is of somewhat uncertain composition; it may perhaps be described as a mixture, or rather a semi-compound, of chloride and oxychloride of lime, and its composition may be indicated by the formula $CaOClCl$. This formula is only approximate, and must not at all be taken as comparable with the other formulas we have seen, which are exact. At any rate, bleaching powder contains a superfluity of chlorine which it is always ready to dispose of, and to which it owes its properties.

Another very common salt of calcium is its fluoride, which has the formula CaF_2.* This occurs as a very common mineral, very often in association with the ores of lead, and usually known as *fluor-spar*, or *fluorite*.

It forms very nearly transparent crystals, most frequently cubical. It is hard but brittle, and occurs in a large number of different colours, of which the most common is violet. Sometimes it occurs in alternate bands of violet and colourless structure; this form is known as Derbyshire spa.

Salts of Calcium. The *sulphate of calcium* ($CaSO_4$) is an important salt, which occurs in nature in different forms. One of these, sometimes called *anhydrite*, contains no water, but commoner forms, such as gypsum, contain two molecules of water of crystallisation to each molecule of the sulphate. Other water-containing forms of sulphate of lime are selenite and alabaster. Selenite is practically equivalent to gypsum, and alabaster is almost identical. The latter has a pearly lustre, is never transparent, is quite soft—in this respect these forms contrast markedly with anhydrite—and thus it can be very readily carved or turned; but it must not be exposed to rain, as it is soluble in water, though only slightly. If these forms of sulphate of lime are heated, there is derived the cement-like substance called *plaster-of-Paris*. In practice this is always obtained from the commonest form, which is gypsum. When heated at a temperature considerably above the boiling point of water, it loses its water of crystallisation, and forms a plastic substance which can be moulded to any form, and which on mixture with water speedily sets into a hard, rigid mass, which consists of a union, if not a true chemical combination, between the water and the salt. It is certainly more than a mere mixture of the two. This we know because a good deal of heat is produced as the plaster sets, and the evolution of heat is an invariable sign of the satisfaction of chemical affinity.

The *sulphide of lime* (CaS) is luminous in the dark, and may, therefore, be used to amuse children, and so forth. At one time it was largely employed in medicine, but is probably of no particular value as a drug.

The *phosphate of lime*, a compound of lime and phosphoric acid, occurs in nature as a mineral called *apatite*. It is constantly found in the animal body, forming some 60 per cent. of the structure of the bones, and even a higher proportion of the teeth. Minute quantities of the fluoride of calcium are also found in teeth.

Barium. Barium is a very heavy metal, which closely resembles calcium in many of its chemical properties. It has recently obtained much fresh theoretical importance from the fact that it seems to have certain relations to radium. Its atomic weight is about 137. Its name is derived from the Greek word *barys*, heavy. Barium is never found in the elemental state in nature, but occurs in the form of two salts—the sulphate, which forms the mineral known as *barytes*, or *heavy spar*, and the carbonate. Like sodium and potassium, barium was first isolated by Sir Humphry Davy; its oxide closely corresponds to the oxide of calcium, and has a similar formula BaO. It is known as *baryta*. The characteristic colour produced by barium salts when they are heated to incandescence is green, and some of them, such as the chloride and nitrate, are often used in fireworks for this purpose. Barium also forms a dioxide (having the formula BaO_2), as indeed does calcium. The calcium salt is of no importance, but the barium salt is used as a means of preparing oxygen in large quantities. In the first place the salt is formed by heating the ordinary oxide to dull redness in air, from which it takes a certain amount of oxygen so as to form the dioxide. When this is heated still further it gives off the extra oxygen which it has taken up at a lower temperature. Instead of raising the temperature further, the same changes may be made to occur by altering the pressure, which comes to the same thing. Air is forced into tubes containing the oxide, the dioxide being formed whilst the nitrogen of the air escapes. Then when the pressure is lowered, the oxygen previously taken up is given off again, and can be collected.

---

* If the reader is not sure that he knows what these formulas mean, he should turn back to the place where they are discussed.

Strontium. The last element dealt with in this group is *strontium*, which is of less importance than any of the others. Its atomic weight is about 87·5, and its chemical symbol Sr. It also was first discovered by Davy, being *prepared, as we have already seen, by electrolysis of the fused chloride. It is a yellowish, malleable metal,* which readily oxidises on exposure to the air, and also decomposes water in the fashion which should now be familiar. It is found in nature in the form of the sulphate and carbonate. As in the case of barium, its chloride and nitrate are soluble, and can be used, especially the latter, in fireworks. It produces a splendid crimson colour. The sulphate of strontium is peculiar in that it is less soluble in hot water than in cold.

Magnesium and zinc are the next two metals to be discussed, since they form a group. They are both metals heavier than water, but, unlike the preceding metals, not liable to act upon it, save slightly, if the water be boiled.

Magnesium. Magnesium is not found in the elemental form in nature, but is abundant in certain compounds. Of these the commonest are the carbonate, the double carbonate of calcium and magnesium, which is known as *dolomite*, the sulphate (which occurs, for instance, as the mineral Epsomite, reminding us of the medicinal use of the sulphate of magnesium, or Epsom salts), *carnallite*, which is a double chloride of magnesium and potassium, and in the form of various mixed silicates, such as *asbestos*, *tourmaline*, and *meerschaum* (literally sea-foam). Again it is Sir Humphry Davy who has the distinction of having first isolated magnesium. The metal is now prepared from its chloride, from which it is displaced by means of metallic sodium. It is extremely light, insoluble in water, but readily soluble in acids. Its atomic weight is 24, and its symbol Mg. The reader must not confuse magnesium (with the symbol Mg), and manganesium, or manganese, which has the symbol Mn. When magnesium is heated in air it burns with an exceedingly brilliant light, and forms the oxide of magnesium MgO. This is usually known as magnesia; and is a tasteless, insoluble, light, white powder of considerable use in medicine. It is not, however, usually prepared by the oxidation of magnesium, but by heating magnesium carbonate, which salt is decomposed, giving off carbonic acid in a manner exactly similar to the decomposition of calcium carbonate and the formation of quicklime.

The light produced by the oxidation of magnesium is not only extremely brilliant, but is especially rich in those rays of light which are most markedly powerful in their chemical action on a photographic plate. Hence it is largely used for photography.

Zinc. Zinc has the symbol Zn, and its atomic weight is 65. It occurs in nature only in combination in the forms of carbonate, usually known as *calamine*, and the sulphide, which is known as *blende* or "black-jack." Calamine is of no particular importance; sometimes it is powdered, carefully purified and tinted, for application to the face. It is from the blende that metallic zinc is prepared. The blende is roasted in air, yielding zinc oxide and the oxide of sulphur, which is volatile, and escapes. The oxide, which is a powder, is treated with charcoal, which takes the oxygen from it. The operation is conducted at a high temperature, at which the zinc is produced in gaseous form. It is never obtained pure by this process. Zinc does not tarnish readily in the air, and so may be used for coating sheets of iron, and thus protecting them from the atmosphere. Iron thus treated is known as galvanised iron. The zinc is not affected even if the air be moist. When zinc is strongly heated, it readily burns and forms an oxide (ZnO). This oxide is of some use in medicine, being incorporated with lard as zinc ointment, which is soothing, and very feebly antiseptic. The chloride of zinc, having the formula $ZnCl_2$, is obtained by evaporating a solution of zinc in hydrochloric acid; it is a very powerful antiseptic, and is the basis of Burnett's Disinfecting Fluid. Zinc forms some important alloys. With copper it forms brass, which is made by melting the copper and adding zinc to it; with tin it forms bronze, and with copper and nickel it becomes "German silver."

Boron. The next group of elements we have to consider consists of boron and aluminium, the latter of which is promising to become of great importance. Boron has the symbol B, and its atomic weight is about 11. It is not to be regarded as a metal. It was first isolated in 1808, the year following the discovery of sodium and potassium. It is not found in the elemental form in nature, but occurs chiefly as borax, already discussed under sodium. Borax has a very feeble antiseptic property, but this is decidedly more marked in boric acid, or boracic acid, which is derived by the union of water with the oxide of boron. This oxide has the formula B_2O_3. Boracic acid may be obtained by the action of a strong acid upon borax, but this method is not usually employed, since the acid occurs in nature in certain springs in Tuscany. From the water of these springs it may be prepared by evaporation. The uses of the acid as a mild antiseptic are familiar. Boron also occurs in large quantities as the mineral called boracite, which is a compound or combination of the borate of magnesium and the chloride of magnesium. It occurs in association with gypsum and with common salt in some parts of Germany. It is of no practical importance, and the same may be said of all the other compounds of boron.

Aluminium. The next metal with which we have to deal—aluminium—is exceedingly abundant, as we have already seen, and has lately become of very great commercial and practical importance. It is a white metal, specially characterised by its extreme lightness. Its specific gravity—that is to say, its weight compared to the weight of water represented as 1 [see PHYSICS]—is only 2·6. Besides this extreme lightness, which is often of much practical value, aluminium has other useful physical properties. It is ductile, and can be drawn into wire; it can also be readily cast, and can be rolled into sheets. It melts at the comparatively low temperature of 700° C. Aluminium tarnishes very slowly on exposure to air, but it forms alloys which are in this and some other respects more valuable than itself. Its alloy with copper, for instance, known as aluminium-bronze, is scarcely liable to tarnish at all. It is of a yellowish colour.

Though so abundant, being a constituent of most rocks, and the characteristic element of clay, aluminium, until very recent times, has been very expensive to obtain in a pure state. It has had to be extracted from clay by a series of very difficult operations. At the present time, however, aluminium is prepared by an electrical method which has enormously reduced its cost. The principle is that of electrolysis, consisting essentially in the passage of an electrical current through solutions containing the required product. The method in present use is now nearly 20 years old. The material employed for electrolytic production is a mixture of cryolite—the double fluoride of aluminium and sodium, with alumina—the oxide of aluminium.

The widest practical use of this metal at the present time is in the purification of iron and steel—a use which is due to the fact that the metal at high temperatures is able to decompose the oxides of nearly all other metals. It makes excellent cooking utensils, which do not break or chip or rust, are exceedingly light, and make no poisonous contribution to the food cooked in them. It is also largely coming into use in the place of copper as a conductor of electricity.

The compound alumina, which has already been mentioned, may be prepared as a white powder, which is characterised by its great affinity for colouring matters, and is thus largely used in dyeing and colour manufacture. The substance formed by the union of the colouring matter and the alumina is usually known as a *lake*. In its crystalline form alumina is second only to the diamond in the scale of hardness. [See PHYSICS.] Tinted by various impurities, it forms some of the most beautiful of precious stones, such as the ruby, the sapphire, and the amethyst.

A New Group. Our next group consists of one exceedingly important element, *iron*, and four of less importance, *chromium*, *manganese*, *cobalt*, and *nickel*. The sources of these metals are as follows. Chromium occurs mainly as chrome-iron ore, which is a double oxide of iron and chromium; manganese occurs in the form of its oxide, which has the formula MnO_2, nickel occurs in New Caledonia in the form of a silicate of nickel and magnesium, and both nickel and cobalt are found in nature in combination with arsenic.

These metals can be obtained in the pure metallic state by means of carbon, which turns them out of their oxides. We may first of all dispose of the four unimportant members of this group before going on to deal with iron, which demands lengthy consideration.

Chromium. Enough has already been said about the source and preparation of this metal; it is extremely hard, and of a grey-green colour. It combines with oxygen in various proportions, the most important compound of the two elements being chromic oxide, which has the formula Cr_2O_3. This is sold as a pigment under the name of emerald green, an accurate name, since the colour of the emerald is due to small quantities of chromium. There is also a double sulphate of chromium and potassium, which is known as chrome alum. The name is a bad one, since it contains no aluminium. The salt forms purple crystals, which are much employed in dyeing, calico printing, etc.

Manganese. Manganese, which must never be confused with magnesium, occurs in nature in several combinations besides the black oxide (MnO_2) already mentioned. Prepared as stated above, it is a very hard, brittle, whitish metal, which cannot be preserved in air, since it rapidly decomposes the water contained in air, becoming itself oxidised and giving off hydrogen.

Naturally enough, metallic manganese has no commercial uses, but its oxides are used in glass-making; and its alloys with iron, with which it frequently occurs in nature, are very valuable, as such iron yields very superior steel.

A very useful compound of manganese is the salt known as permanganate of potassium, which has the formula $KMnO_4$. It occurs in the form of small purple crystals. When these are dissolved they form a deeply coloured solution, with a very unpleasant taste, which is familiar to everyone under the name of Condy's Fluid. This compound contains an excess of oxygen, which, in the presence of water, it is very ready to give up to organic bodies. In consequence of the decomposition which then occurs, the solution loses its purple colour and becomes a dirty brown, due to the formation of the black oxide of manganese. This change in colour has the advantage that it enables one to see whether or not solutions of the salt have undergone decomposition. The solutions of this salt have been largely praised as antiseptics, and are still very generally believed in, but its virtues have been very much exaggerated. It should be looked upon rather as a deodoriser than as a true antiseptic. It has only very slight action against microbes, but it helps to complete the oxidation of the products of their action, and thus removes foul smells. Unfortunately it readily stains linen, cotton, and the like, but the stain may be removed by applying sulphurous acid and then immediately washing out the fabric in water. The oxidising properties of this salt have been found to render it very useful as an antidote in morphia poisoning. It oxidises any morphia that may remain in the stomach, whether taken as such or in the form of opium, and thus prevents it from acting.

Cobalt. This is a reddish-white metal, found, as stated, in combination with arsenic, and also as *cobalt glance*, which is a compound of cobalt, arsenic and soda. Compounds of cobalt, having a blue colour, are used as pigments, and also for giving a blue colour to glass and porcelain.

Nickel. Nickel is a metal of somewhat more importance than the others, chiefly in virtue of its use in strengthening steel. Nickel steel—that is to say, steel containing a small percentage of nickel—is so much harder than ordinary steel that it is said to offer about 20 per cent. better protection as armour-plate for ships than the best ordinary steel. Nickel is also used in the form of an alloy with copper for the manufacture of coins. The subject of nickel-plating is treated elsewhere. The metal closely resembles the others of this group. It is of a silvery white colour, very hard, though malleable, and melts at a very high temperature.

Iron. Iron is, of course, by far the most important and useful of all the metals, having an extraordinary variety of uses, and being important in manufacture, in the arts, and in medicine. Very small quantities of the metal are found in the pure state on the earth, and these only in rocks of volcanic origin. Iron, however, appears to occur extensively in its uncombined form in the heavens, and uncombined or metallic iron is found in quite considerable quantities in meteorites. [See ASTRONOMY.] The most valuable ores of iron are various oxides and the carbonate, these being the compounds of commercial importance. The magnetic oxide of iron, sometimes called *magnetite*, has the formula Fe_3O_4. Another oxide (Fe_2O_3) is known as *hæmatite*, and this occurs in several forms. The carbonate, no less important, occurs in what is called *spathic iron ore*, clay ironstone, or clay band, in which it is mixed with clay; and as *black band*, in which it is mixed with coal. Large quantities of these ores occur in this country. Other compounds also have a wide distribution. Iron pyrites, for instance, which has the formula FeS_2, is used less as a source of iron than as a source of sulphur. Various silicates of iron occur in many rocks and minerals.

The Extraction of Iron. In order to extract iron from its ores, the first thing to do is to perform the process of calcination, which consists of roasting the ore so as to break it up, to expel water and any gases it may contain, and also to burn off the sulphur which may be present. The ores are then ready for treatment in the blast furnace, where they are heated with coal and lime, the first being simply a convenient form of carbon used in order to remove the oxygen from the ore, and the lime being used as a flux, which forms with the sand in the ore a fusible glass called slag. This floats on the molten iron, and has to be removed at intervals.

The blast-furnace is a hollow tower, which may be as much as 100 ft. high, and which contracts towards its lower part, having at its very bottom the crucible where the actual operation occurs. Above the crucible are tubes through which there passes an incessant blast of hot air; this blast makes the combustion much more rapid, and therefore produces a much higher temperature. The exact sequence and nature of the chemical changes in the blast-furnace are not precisely known, but what happens is essentially this. The coal is oxidised to form carbonic oxide (CO), and this, which requires more oxygen, takes it from the oxide of iron; there is thus formed carbonic acid (CO_2), which escapes from the mouth of the furnace. Meanwhile the molten iron sinks in the furnace, while fresh layers of coal, lime, and ore have to be added from above. The resultant product is by no means a pure iron.

In the first place it contains a certain percentage of carbon derived from the coal, and in the second place a good deal of silicon derived from the earth and sand with which the ore is mixed up. This substance is known as *cast iron*, or sometimes as *pig-iron*; the bars which are formed by running off the molten iron from the crucibles being known as pigs. This iron contains, besides carbon and silicon, a certain amount of sulphur, phosphorus and manganese, though none of these are nearly so abundant as the carbon. There are three kinds of pig-iron, the differences between them depending upon the state of the carbon in them. If the iron cools very rapidly into the moulds into which it is run, the carbon remains combined with the iron, which is then white, and is called *white pig*; but if the cooling occurs slowly the carbon separates out in the form of black crystals of graphite [see CARBON, page 1046], and the iron is then called *grey pig*; whilst intermediate between grey pig and white pig is *mottled pig*.

Wrought Iron. Now, this kind of iron is very brittle. It cannot be forged or welded; the only use to which it can be applied is castings. When the pigs are remelted in small furnaces they may be employed for this purpose, which is facilitated by the fact that cast iron expands slightly as it solidifies. Now, what we want for purposes of forging and welding is a substance that shall have the strength of cast iron without its brittleness, and that substance, of course, is *wrought iron*. The difference between cast iron and wrought iron depends upon the fact that in the latter the impurities have been burnt out. This is done by melting the iron and exposing it in the molten state to blasts of hot air, which remove most of the carbon and silicon in the form of their oxides. This is the process known as *puddling*, the name being derived from the necessity of stirring the mass to a pasty consistence. The lumps of iron which are subjected to the puddling process are called *blooms*. Wrought iron is the purest form of iron that is found in commerce. It can be forged and welded, and even drawn into wire. It has a specific gravity of 7·6—somewhat greater than that of cast iron, which is less than 7·5—and has a rather higher melting point than cast iron, which melts at about 1,500° C. Before it melts, wrought iron becomes pasty, and can thus be welded at white heat. It contains usually less than one-half per cent. of carbon as compared with the 3 to 5 per cent. which occurs in cast iron.

The Bessemer Process. Wrought iron may be manufactured in a more satisfactory way than by puddling, and this is known as the Bessemer process, in which a current of air is blown through fused pig-iron in a pear-shaped vessel, itself made of iron and lined with firebricks. This leads us on to the important subject of steel. Steel contains less carbon than cast iron, but rather more than wrought iron, the percentage of carbon being from 1 to 1·5 ; it melts at 1,800° C., and has a specific gravity of 7·6 to 8. It used only to be made by the *cementation process*, which consisted in placing bars of wrought iron in boxes, surrounding them with powdered charcoal, and then heating them for days at a time. Nowadays the manufacture of steel is accomplished by adding another stage to the Bessemer process already described. This is done by adding to the wrought iron a certain amount of cast iron—the percentage of carbon in which is known—while it lies in the Bessemer converter where it has been made. This process is named after Sir Henry Bessemer, who introduced it in 1856. The converters are now lined with a substance called ganister, which is a compound of silicon, and whilst the liquid metal lies in them, air is blown into it by engines from below. The ordinary dose of metal for a converter may be as much as 10 tons, and this may all be converted in half an hour. No wonder that more than 30 times as much steel is now turned out as before 1856, and at only about one-fifth of the former cost.

Basic Steel. To manufacture steel from pig-iron that contains phosphorus there has been introduced a method which is a simple modification of the Bessemer process. Instead of having a silicious lining like the ordinary Bessemer converter, the basic Bessemer converter has a lining of magnesium limestone and tar. This will withstand almost any temperature that successfully effects the removal of the phosphorus.

It is still somewhat uncertain how we are to describe steel from the purely chemical point of view. The difference between steel and pig-iron, or cast iron, is certainly very much more than a mere difference in the proportion of carbon that each contains. The carbon in cast iron is not really combined with the iron. The carbon in steel is either combined with the iron or dissolved in it, and it is this that doubtless constitutes the essential difference. The objection to the presence of phosphorus in steel in quantities greater than 1 per cent. is that such steel is brittle, or *cold-short*. A still smaller percentage of sulphur also makes the steel brittle, and such steel is called *red-short*. The same applies to the presence of silicon and other impurities. Steels containing a considerable percentage of carbon—anything above ¼ per cent.—may be rendered so hard by heating to redness and sudden cooling that they will scratch glass. But very hard steel is also very brittle, and in order to remove the brittleness such steel must be annealed or softened by a second process of heating and cooling. Mild steel is now employed for all purposes for which wrought iron was formerly employed. A steel rail will last about eleven times as long as an iron one.

The Bessemer process, though it has revolutionised the whole subject of steel, is nevertheless open to certain criticism. It does not produce the purest form of steel, in order to obtain which we must go back to the cementation process already described, using the purest Swedish iron.

Iron Chemically Considered. We must now proceed to consider iron from the chemical point of view. The best way in which to obtain absolutely pure iron is by the action of hydrogen gas upon one of the oxides of iron, which the hydrogen *reduces*. To reduce a body is to take oxygen from it, hence a reducing agent itself undergoes oxidation whilst effecting the reduction of something else. But this pure iron is very unstable, for in the presence of moisture and air it rusts very rapidly, forming various compounds, such as the oxide. For practical purposes, therefore, the surface of the iron requires to be treated with something which will withstand the action of the air. Such a substance is zinc, or, rather, an alloy of zinc and iron. When thoroughly clean, wrought iron is dipped into a bath of melted zinc, which is deposited upon it. This *galvanised iron*, as it is called for some mysterious reason, is in wide use in virtue of its resistance to all atmospheric action. Similarly, the iron may be coated with tin, yielding the product of which we have lately heard a good deal, called *tin plate*.

Iron has very marked magnetic qualities. The *lodestone*, for instance, formerly used as a compass by sailors—lodestone seems to mean "leading stone"—is an oxide of iron, and has the formula Fe_3O_4. It is now usually known as magnetite, or the magnetic oxide. Other forms of iron are also capable of easy magnetisation—that is to say, they respond to the attraction of magnets, and can themselves be converted into magnets. Steel has similar properties, with greater power of maintaining the magnetic quality.

The other important oxides of iron are ferrous oxide, which has the formula FeO, and ferric oxide, which has the formula Fe_2O_3.

Difference between "ous" and "ic." Here we may explain, once and for all, the use of these two terminations "ic" and "ous." When the Romans wanted to express fulness, they made an adjective terminating with the syllable *osus*, as for instance, *amorosus*. In English, we contract this to *ous*, and this termination of English words always has the same meaning as the Latin termination *osus*. For instance, there is our word amorous. Similarly, in chemistry, whenever the salt of a base contains more of that base than another salt, we describe the first by the termination *ous*, and the second by the termination *ic*. Hence, a ferrous salt, or a mercurous, or a stannous, tells us by its name that it contains more iron or mercury or tin than a ferric salt, a mercuric or a stannic.

Other ways of expressing the proportion of the base in a salt must be noted. They consist in attaching the prefixes *per* and *sub* to the second half of the name of the salt. For instance, the salt FeCl$_2$, which contains more iron proportionately than the salt FeCl$_3$, is usually called ferrous chloride, whilst the second is called ferric chloride. But the salt may be looked at in another way. We may say that the amount of chloride in the first salt is *sub*, which means under; whilst the amount of chloride in the second salt is *per*, which means through, or thorough, as in the word perfect. Hence, another name for ferrous chloride is subchloride of iron, whilst another name for ferric chloride is perchloride of iron, and we may speak when we please of the "sub salts" and the "per salts," to distinguish the two series. Let us now make a little table giving instances of the use of these terms:

Ferric chloride, or Perchloride of iron, or FeCl$_3$.	Ferrous chloride, or Subchloride of iron, or FeCl$_2$.
Mercuric chloride, or Perchloride of mercury, or HgCl$_2$.	Mercurous chloride, or Subchloride of mercury, or HgCl.

Iron in the World of Life. We cannot leave our consideration of this metal without referring to its *rôle* in living matter. Iron is found in all the higher plants and animals; indeed, it is possible that it may occur in every living thing. It is thus an essential ingredient of the food of animals and of plants. In all the higher animals and plants—the term higher must here be taken as meaning all but the very lowest—iron gives rise to very characteristic substances which have a distinctive colour. Iron is indeed responsible for the colour of life in both the animal and the vegetable world. The characteristic colouring matter of the animal is the red of its blood. This red is due to an exceedingly complicated substance—believed by most chemists to have the most complicated molecule that is known—which is called *hæmoglobin*. In every molecule of this substance there is always one atom of iron. The process of breathing depends essentially upon the presence of this substance, which has the power of taking up oxygen from the air in the lungs, and then carrying it by means of the circulation to the tissues which need it.

The colour of life in the plant is the green of its leaves. This green substance, which is found occurring in minute granules situated at the circumference of the cells of the leaf [see BOTANY], is known as chlorophyll, and iron is an essential constituent of it. If a plant be nourished in such a fashion that no iron can gain access to it, it will come up blanched, containing no chlorophyll whatever, will very soon die, and will be unable to propagate itself. The service which the iron performs for the plant is exactly the converse of that which it performs for the animal, for whilst it enables the animal to help itself to oxygen from the air—oxygen which is then combined with carbon, and given back to the air in the form of carbonic acid, CO$_2$—it enables the plant to decompose the CO$_2$ in the air, taking the carbon into itself, as the most precious ingredient of its food, leaving the oxygen behind. Ultimately the tissues of the plant serve as food for the animal, which oxidises them by means of the oxgyen obtained in the manner we have described. So the round continues, and the reader will see that iron thus plays an all important and double part in that incessant and complementary series of chemical changes in the animal and vegetable world which has been called the cycle of life.

Carbon the Most Important Element. The next element which we have to consider is known as *carbon*. It is the most important of all the elements, and needs very detailed consideration. In the first place we must note that the chemistry of carbon has two distinct aspects, only one of which we can deal with at present. Reference has already been made to the fact that what used to be called organic chemistry is now known as the chemistry of the carbon compounds, and to that we must return later. Here we shall have quite enough to do to consider carbon in its behaviour uncombined, or forming the simplest compounds with oxygen.

Unlike the elements which we have lately been considering, carbon is not a metal. It may be obtained from compounds, such as the oxide, by means of hydrogen or potassium at a red heat, since these elements will reduce the oxide and leave free carbon behind. Perhaps the purest carbon, however, is prepared by heating sugar, which is a compound of carbon, hydrogen and oxygen. If sugar be heated to redness in a closed crucible, it is charred—that is to say, the other elements are driven off, and carbon alone remains.

But carbon occurs in nature in the uncombined state, or, rather, in several states. The *diamond* is a form of carbon, so is *charcoal*, and so is *graphite* (from the Greek *grapho*, I write), which is the so-called lead of lead-pencils. Now, this fact—that carbon may exist in such widely different forms—is an illustration of a general property which many substances possess, and which we cannot do better than digress to discuss here.

Allotropy. Allotropy is the name applied to this property. It is sometimes also called physical isomerism. Chemically, the substance in question is the same in each case. Physically, it differs profoundly; sometimes it is crystalline, as in the case of the diamond; sometimes it forms crystals of an entirely different kind, such as graphite; and sometimes it is not crystalline at all, like charcoal. The technical name for a substance which is not crystalline is *amorphous*, literally meaning shapeless. Other elements have this property of allotropy besides carbon, instances being phosphorus and sulphur; and numerous compounds have the same property, such as silica, the oxide of silicon, which occurs in the amorphous state, and also in crystalline forms, such as the agate and quartz. The explanation of allotropy is hard to discover; perhaps the most obvious fact connected with it is that the change of physical state usually depends upon a change in temperature. Let us now return to the various allotropic forms of carbon.

By Gerald K. Hibbert, M.A.

SECTION I. GRAMMAR

Frequentative Verbs. These express repeated or intenser action, and are formed either (1) in *-to*, *-so*, from supine stems—*e.g.*, *tracto* = I handle (from *traho*, *traxi*, *tractum* = I draw); *curso* = I run about (from *curro*, *cucurri*, *cursum* = I run); or (2) by adding *-ito* to the last consonant of the present stem—*e.g.*, *rogito* = I ask often. All Frequentatives are first conjugation.

Inceptive Verbs. These express beginning of action, and are formed by adding *-sco* to the present stem of verbs, or from nouns by adding *-asco* or *-esco*—*e.g.*, *juvenesco* = I begin to grow young; *ignesco* = I burst into flame. All these are third conjugation.

Desiderative Verbs. These express desire, and are formed by adding *-urio* to the supine stem—*e.g.*, *esurio* = I am hungry (from *edo*, *esum* = I eat). All these are fourth conjugation.

Quasi-Passive Verbs. These are the exact opposite of Deponents. Deponents are passive in form and active in meaning; Quasi-Passives are active in form and passive in meaning—*e.g.*, *fio* = I am made; *exulo* = I am banished; *liceo* = I am put to auction; *vapulo* = I am beaten; *veneo* (compound of *eo* = I go) = I am on sale (used as the passive of *vendo* = I sell).

Defective Verbs. These lack some of a verb's usual parts:

1. *Odi* (I hate), *memini* (I remember), *cœpi* (I begin), are perfects, without any present-stem tenses. *Novi* (I know), from *nosco*, is similarly used. Thus: "To hate" = *odisse*; "I remembered" = *memineram* (pluperfect).

Memini has Imperative *memento*, *mementote*.

Cœpi and *odi* have perfect and future participles—*cœptus* and *cœpturus*, *osus* and *osurus*.

2. Many verbs have perfect without supine, and some have neither perfect nor supine—*e.g.*, most of the Inceptive verbs.

3. *Inquam* (I say) has the following parts:

	1.	2.	3.
Present:	inquam	inquis	inquit
	inquimus	inquitis	inquiunt
Imperfect:	—	—	inquiebat
	—	—	inquiebant
Future:	—	inquies	inquiet
Perfect:	—	inquisti	inquit
Imperative:	—	inque	—
	—	inquite	—

Aio (I say ay, I affirm) has:

	1.	2.	3.
Present:	aio	ais	ait
	—	—	aiunt
Imperfect:	aiebam (complete)		
Pres. subj.:	—	aias	aiat
	—	—	aiant

Fari (to speak)—deponent—has: *Fatur* (he speaks); *fabor* (I shall speak); *fare* (speak thou); *fari*, *fatus*, *fandus*.

Impersonal Verbs. These are conjugated only in the third person singular of the finite verb, and in the infinitive. They can be in any tense.

1. The following are used with the accusative: *Oportet* (it behoves), *decet* (it beseems), *dedecet* (it misbeseems), *piget* (it irks), *pudet* (it shames), *poenitet* (it repents), *taedet* (it wearies), *miseret* (it moves pity)—all second conjugation; also, *delectat* (it charms), and *juvat* (it delights)—first conjugation.

2. The following are used with the dative: *Libet* (it pleases), *licet* (it is lawful), *liquet* (it is clear)—second conjugation; also, *accidit*, *contingit* (third), *evenit*, *convenit*, *expedit* (fourth).

Examples: *Oportet me ire* = I must go. *Licuit tibi ridere* = You were allowed to laugh.

3. *Pudet*, *piget*, *taedet*, *poenitet*, *miseret*, are used with an acc. of the person feeling, and a genitive of what causes the feeling: *Taedet me vitae* = I am weary of life. *Tui me miseret*; *mei piget* = I pity you; I am vexed with myself.

4. *Interest* and *refert* (it concerns, or it is important for) take the *genitive* of the person concerned—*e.g.*, *Caesaris interest pontem facere* = it is Cæsar's interest to build a bridge. [This construction is rare with *refert*: say, *ad Cœsarem refert*.] But *possessive pronouns* are used in the *ablative feminine*—*e.g.*, *Quid meā refert* = What does it signify to me? *Magis nullius interest quam tuā* = It concerns no one more than yourself*.

Irregular Verbs: First Conjugation. The following are the most important exceptions:

Perfect—*ui*. Supine—*itum*.

crepo	crepare	crepui	crepitum	*creak*

---

* The *meā* and the *tuā* probably agree with *re* understood. *Meā re fert* was originally *meae rei fert*, and then *rei* being shortened to *re*, *meae* became *mea*. If this is so, *mea interest* is probably an imitation.

Similarly, *cubo* (*lie down*), *domo* (*tame*), *plico* (*fold*), *sono* (*sound*), *tono* (*thunder*), *veto* (*forbid*).

Perfect—*ui*. Supine—*tum*.

seco	secare	secui	sectum	*cut*

Perfect reduplicated. Supine—*tum*.

do	dare	dedi	datum	*give*
sto	stare	steti	statum	*stand*

Perfect—*vi*. Supine—*tum*.

juvo	juvare	juvi	jutum	*help*
lavo	lavare	lavi	lotum *or* lavatum	*wash*

NOTE. Compounds of *do* are of third conjugation, and make *-didi*, *-ditum* (except *circumdo*, *pessumdo*, and *venumdo*, which make *-dedi*, *-datum*). Compounds of *sto* form *-stiti*, *-stitum*.

SECTION II. COMPOSITION

The Oratio Obliqua. This construction, known also as Oblique Narration, or the Accusative and Infinitive Construction, is one of the most characteristic idioms of Latin. It is especially used where English has a clause beginning with *that* after (1) verbs of *saying*, *knowing*, *thinking*, *believing*, *feeling*; (2) impersonal expressions, as "It is clear, true," etc.

Rule 1. The subject is put in the acc. case, and all principal verbs are changed from indicative to infinitive, retaining their original tenses—*e.g.*, He says that the moon is smaller than the sun = *dicit lunam esse minorem sole* (literally, He says the moon to be smaller). I know that I shall die = *scio me moriturum esse*.

[Instead of *dico* . . . *non*, Latin uses *nego* = I deny—*e.g.*, He said he did not believe = *negavit se credere*.]

Rule 2. All verbs, other than principal verbs (*i.e.*, verbs directly making a statement), are put in the subjunctive. There cannot be an indicative in Oratio Obliqua. This is very important.

Examples: "The slaves whom I now have here are most faithful" is in Oratio Recta (Direct Narration), and would be in Latin, "Servi quos nunc hic *habeo* sunt fidelissimi." Turn this into "reported speech," or Oratio Obliqua, and we have "He said that the slaves whom he then had there were most faithful" = dixit servos quos tum ibi *haberet* esse fidelissimos. [Note the change of "now" into "then," "here" into "there," "I" into "he," "have" into "had," and "are" into "were"; but we still use "esse" for "were," because "esse" is both present and imperfect infinitive, and "fuisse" would mean "had been."] Again, "It is clear that, because the citizens are cowards, the city will be taken" = manifestum est quod cives ignavi *sint*, urbem captum iri.

Rule 3. Imperatives in Oratio Recta become imperfect subjunctive in Oratio Obliqua—*e.g.*, *Recta*: "Charge, my men," said the general = *Instate, milites, inquit imperator*. *Obliqua*: "The general said to his soldiers, 'Let them charge,'" = imperator militibus dixit, Instarent.

Rule 4. Questions in the first and third persons are rendered in Oratio Obliqua by the accusative of the person and the infinitive of the verb; but questions of the second person become imperfect or pluperfect subjunctive—*e.g.*, (They said) Why is our general absent? = *cur abesse imperatorem?* (He said) Why are you advancing? = *cur progrederentur?*

Rule 5. *Ego*, *tu*, *nos*, *vos*, cannot find a place in Oratio Obliqua; *me* and *nos* become *se*, *tu* becomes *ille*, and *vos* becomes *illi*.

Se and *suus* refer, as a rule, to the speaker—*e.g.*, He says that he will come = *dicit se venturum esse*.

He said, "Let them not forget his kindnesses" = *ne suorum beneficiorum obliviscerentur*.

If, however, *suus* is wanted to refer to the subject of some subordinate verb (*e.g.*, *obliviscerentur*, above), then *ipse* is used to refer to the speaker—*e.g.*, Let them not forget their own cowardice or his kindnesses = *ne suae ignaviae aut ipsius beneficiorum obliviscerentur*.

NOTE. The translation of the English conjunction *that* needs great care. When it means "in order that," "so that" (as "He walked fast that he might warm himself"), it should be translated by *ut* with subjunctive. When it means "the fact that," after any verb or phrase *sentiendi vel declarandi* ("of feeling or stating") the accusative with the infinitive must be used. In English we can say, "You were ill, he thought, and therefore absent." But in Latin we must say, "He thought that you were ill, etc." (*Putavit te aegrotare*).

TO BE TURNED INTO LATIN PROSE.

The inhabitants of this island were so bold that they would have preferred a thousand deaths (*say*, "to die six hundred times") to disgrace, if the choice had been necessary. One brave farmer was asked why he would sooner die nobly on the field of battle than live ignobly at home. He answered, "Because I am more afraid of shame than of death." It happened once that they were invaded by the powerful nation of the Ventidii, who landed on their shores, marched up to their capital, devastated the country all round, and then laid siege to the city. The citizens determined to resist with boldness. Instead of throwing themselves at their enemies' feet, they sent away their families, their old men, and their treasures, and prepared to resist with desperation. Though they were prevented by scruples from committing suicide, they promised one another to fight so desperately that the enemy should not take them alive. When they were all assembled in arms, their general addressed them thus: "Remember, citizens, that victory or death awaits you. I will say no more; the enemy is at the gates. What reason is there for delaying?"

LATIN VERSION OF THE ABOVE EXTRACT.

[Latin prose composition can be learned only by long and constant practice. The student is advised to translate the following Latin version *literally* into English, and then compare his English version with the English version as given above. This will give him a good idea of the difference between the English and the Latin ways of expressing ideas. Accuracy and clearness are the first essentials, and then the style should be polished by constant comparison with the style of the best Latin authors, such as Livy and Cicero. Hints on style will be given from time to time during the remainder of this course.]

Qui in hac insula habitabant ii omnes quum essent summa audacia præditi, sescentiens mortem quam semel, si optandum fuisset (*gerundive* = "if it had to be chosen, if choice had to be made") infamiam obire maluissent. E quibus agricola quidam, vir fortissimus, rogatus cur potius vellet militiæ per virtutem emori quam per dedecus domi vivere, respondit se ignominiam magis quam mortem timere. Quibus ita accidit ut Ventidii, quæ gens erat potentissima, in eorum fines navibus ingressi, agris undique vastatis, urbem quam maximam habebant obsiderent. Sed quum civibus visum esset sibi quam acerrime hostibus obstandum (gerundive), tantum aberat ut se iis ad pedes dejicerent ut, pecuniis et liberis et senibus dimissis, sese ad resistendum accingerent ut (as) qui de suis rebus desperarent. Religione quidem obstricti quominus sibi mortem consciscerent, alii tamen aliis pollicebantur sese acrius pugnaturos quam qui ab hostibus vivi caperentur. Quos quum armatos imperator convocasset (shortened form of *convocavisset*), jussit meminisse aut victoriam aut mortem obeundam: se non plura dicturum; hostes illis ad portas adesse: quid causæ (partitive genitive, literally "what of reason") esse cur jam morarentur?

SECTION III. TRANSLATION

PERORATION OF CICERO'S SECOND PHILIPPIC SPEECH.

Respice, quæso, aliquando rempublicam, M. Antoni: quibus ortus sis, non quibuscum vivas considera: mecum, ut voles: redi cum republica in gratiam. Sed de te tu videris: ego de me ipso profitebor. Defendi rempublicam adolescens, non deseram senex: contempsi Catilinæ gladios, non pertimescam tuos. Quin etiam corpus libenter obtulerim, si repræsentari morte mea libertas civitatis potest: ut aliquando dolor populi Romani pariat, quod jam diu parturit. Etenim si abhinc annos prope viginti hoc ipso in templo negavi posse mortem immaturam esse consulari, quanto verius nunc negabo seni? Mihi vero, patres conscripti, jam etiam optanda mors est, *perfuncto** rebus iis quas adeptus sum quasque gessi. Duo modo hæc opto; unum ut moriens populum Romanum liberum relinquam—hoc mihi majus ab dis immortalibus dari nihil potest—alterum, ut ita cuique eveniat ut de republica quisque mereatur.

* "Perfuncto" is dat. of the perf. ptc., agreeing with "mihi": it governs an abl., being compound of "fungor."

●

ENGLISH VERSION OF ABOVE.

Bethink yourself of the State, I beseech you, even now, Marcus Antonius: think of those from whom you have sprung, not of those with whom you now associate: deal with me as you like, but make up your quarrel with the State. About your own course, however, you yourself will decide: I will openly profess my own. I defended the State in my youth, I will not abandon it in my age: I scorned the swords of Catiline, I will not fear yours. Nay, rather, I would gladly offer my body, if by my death the freedom of the State can be immediately recovered, so that at last the pangs of the Roman people may give birth to that with which they have so long been in travail. If, nearly twenty years ago, I said in this very temple that death could not be untimely for one who had filled the consulship, how much more truly shall I say this now of an old man! For me indeed, Senators, death is even to be desired, now that I have completed the course of honour and of achievement.

I have only two wishes. One is that at my death I may leave the Roman people free—and no greater gift than this could be granted me by Heaven! The other is that as each man has deserved of the State, such may be that man's reward.

By Gerald K. Hibbert, M.A.

THE VERB—*continued*

Strong and Weak Conjugations. English verbs are divided into *strong* and *weak*, according to the manner in which they form their Past Indefinite tense.

1. Verbs that form this tense by modifying the vowel of the present tense (without adding any suffix) are said to belong to the *strong* conjugation—as: *shine, shone.* The past participle of all strong verbs originally ended in *-en*, and this ending still remains in many of them (sometimes in the form of *-n*)—as: *break, broke, broken.* The past tense of strong verbs arises from contraction of the original reduplicated form; for this tense was at first formed by reduplication—*i.e.*, by repeating the root of the verb (*cf.* in Latin, *fallo, fefelli,* where the reduplication modifies the root vowel from *a* to *e*). With a few exceptions, all strong verbs are of one syllable only. The exceptions are really compounds of simple verbs, as *forget, beget, awake, abide,* etc.

2. Verbs that form their past indefinite by adding the suffix *-ed*, *-d*, or *-t* to the present tense are said to belong to the *weak conjugation*—as: *treat, treated*; *feel, felt.* When the present tense ends in *e, d* only is added—as, *love, loved.* The vowel *y* preceded by a consonant becomes *i* before this suffix—as: *bully, bullied*; *pay, paid.* A single final consonant preceded by a single vowel is usually doubled before the suffix—as: *drug, drugged*; *travel, travelled.* The

past participle of weak verbs is usually the same in form as the past indefinite. If the present tense ends in *d* or *t*, the suffix is often dropped, and present, past, and past participle have all the same form—as: *cost, cost, cost.*

All the verbs in the Strong Conjugation are of old Teutonic stock. The Weak Conjugation, while including some old verbs and some that were once Strong, is mainly composed of the verbs added at later times—*e.g.*, at the Norman Conquest. Every new verb now added to the language belongs to this conjugation—as: *telephoned, motored, electrified, photographed.*

It is needless to give here a list of all the Strong and the Weak Verbs in the English language. The most interesting verbs, however, and those that present any difficulty, are now given.

Verbs of the Strong Conjugation.

1.

Present.	*Past.*	*Past Participle.*
bind	bound	bound
find	found	found
grind	ground	ground
cling	clung	clung
fling	flung	flung
sling	slung	slung
slink	slunk	slunk
stick(*a*)	stuck	stuck
string	strung	strung
swing	swung	swung
wring	wrung	wrung
begin	began, *or* begun(*b*)	begun
drink	drank, *or* drunk(*b*)	drunk, *or* drunken(*c*)
ring	rang, *or* rung(*b*)	rung
sing	sang, *or* sung(*b*)	sung
sink	sank, *or* sunk(*b*)	sunk, *or* sunken(*c*)
spin	span, *or* spun	spun
shrink	shrank, *or* shrunk(*b*)	shrunk, *or* shrunken(*c*)
spring	sprang, *or* sprung(*b*)	sprung
stink	stank, *or* stunk(*b*)	stunk
swim	swam, *or* swum (*b*)	swum
win	won [old form, *wan*]	won
wind	wound	wound

NOTES. (*a*) *Stick*, now strong, was formerly weak.

(*b*) These forms are not often used now.

(*c*) *Drunken*, *sunken*, and *shrunken* are now used only as adjectives—as: a *drunken* man; *sunken* rocks; *shrunken* flannel.

2.

Present.	*Past.*	*Past Participle.*
blow	blew	blown
grow	grew	grown
know	knew	known
throw	threw	thrown
draw	drew	drawn
hold	held	holden, *or* held
fall	fell	fallen
lie (to recline)	lay	lain
slay	slew	slain
see	saw	seen
drive	drove [old form, *drave*]	driven
ride	rode	ridden
rise	rose	risen
smite	smote	smitten
chide	chid [old form, *chode*]	chidden, *or* chid
hide	hid	hidden, *or* hid
slide	slid	slidden, *or* slid
strive	strove	striven
strike	struck	stricken, *or* struck
thrive	throve	thriven
write	wrote	written
bite	bit	bitten
eat	ate	eaten
beat	beat	beaten
bid (*to order*)	bade, *or* bid	bidden, *or* bid
give	gave	given
forsake	forsook	forsaken
shake	shook	shaken
take	took	taken
come	came	come
bear	bore, *or* bare	borne, *or* born
break	broke, *or* brake	broken
tear	tore, *or* tare	torn
wear	wore	worn
weave	wove	woven
speak	spoke, *or* spake	spoken
steal	stole	stolen
swear	swore, *or* sware	sworn
choose	chose	chosen
freeze	froze	frozen
fly	flew	flown

NOTES. *Fall, fell, fallen* is intransitive; but the kindred verb *to fell* is transitive, and regular of the weak conjugation—as: "The woodman *felled* the tree." *Bare, brake, tare, spake, sware* are not used in modern English.

Borne means *carried*; *born* is used of *birth*, chiefly after the verb "to be." Examples: "Which have *borne* the burden and heat of the day" (St. Matthew); "Where is He that is *born* King of the Jews?" (St. Matthew).

3.

Present.	*Past.*	*Past Participle.*
abide	abode	abode
awake	awoke	awoke
stand	stood	stood
tread	trod	trod, *or* trodden
sit	sat	sat
get	got (gat)	got (gotten)
hang	hung	hung
run	ran	run
burst	burst	burst
shoot	shot	shot
seethe	sod	sodden, *or* sod
spit	spat, *or* spit	spit
fight	fought	fought

NOTES. *Awake*, as a strong verb, is intransitive, meaning "I wake up." When it is transitive, meaning "I rouse some-one," it is weak, and has *awaked, awaked* for its past tense and past participle. Similarly with *hang;* when intransitive it is strong—as: “ He *hung* there for three hours ” ; when transitive, it is weak—as: “ But he *hanged* the chief baker.”

Seethe, meaning *to boil,* is very seldom used now, except in a figurative sense—as: “ A seething mass of men.” The original sense is seen in the expression, “ And Jacob *sod* pottage ” (Genesis). The past participle *sodden* now means “ soaked through.” *Seethe* is now usually weak, making *seethed, seethed.*

Verbs of the Weak Conjugation. 1. Some lose the suffix and shorten the vowel—as:

Pres.	*Past.*	*P.Part.*	*Pres.*	*Past.*	*P. Part.*
bleed	bled	bled	meet	met	met
breed	bred	bred	read	read*	read*
feed	fed	fed	speed	sped	sped
lead	led	led	light	lit	lit

* Pronounced *rĕd.*

2. Some lose the suffix without changing the vowel; but they change the final *-d* into *-t :*

Present.	*Past.*	*Past Participle.*
bend	bent	bent
lend	lent	lent
rend	rent	rent
send	sent	sent
spend	spent	spent
wend	went, *or* wended	wended
build	built	built, *or* builded
blend	blended	blent
gild	gilt, *or* gilded	gilt, *or* gilded
gird	girt, *or* girded	girt, *or* girded

3. Some lose the suffix and show no change at all. The following have the same form throughout: *Cast, cost, cut, hit, hurt, knit, let, put, rid, set, shed, shred, shut, slit, split, spread, thrust,* and *bid* (meaning “ to offer at an auction,” as “ He *bid* £5 for it yesterday ”). *Let,* meaning *to hinder,* comes from *lettan* (to hinder, *cf. late*), while *let,* meaning *to allow,* is from *laetan* (French *laisser*).

4. Some retain the suffix, but shorten or otherwise alter the vowel:

Present.	*Past.*	*Past Participle.*
beseech	besought	besought
buy	bought	bought
catch	caught	caught
bring	brought	brought
sell	sold	sold
seek	sought	sought
teach	taught	taught
think	thought	thought
tell	told	told
work	wrought	wrought
can	could	—
may	might	—
will	would	—
shall	should	—
bereave	bereft, *or* bereaved	bereft
creep	crept	crept
deal	dealt	dealt
dream	dreamt, *or* dreamed	dreamt
feel	felt	felt
flee	fled	fled
hear	heard	heard
keep	kept	kept
kneel	knelt	knelt
lean	leant, *or* leaned	leant
leave	left	left
lose	lost	lost
mean	meant	meant
sleep	slept	slept
sweep	swept	swept
weep	wept	wept
lay	laid	laid
say	said	said
shoe	shod	shod

Verbs of Mixed Conjugation. Some verbs are found in both conjugations, while others either combine a weak past participle with a strong past tense, or a strong past participle with a weak past tense.

Present.	*Past.*	*Past Participle.*
shear	shore	shorn
	sheared	sheared
climb	clomb	—
	climbed	climbed
cleave	clove	cloven
(= to split)	clave	
	cleft	cleft
heave	hove	hoven
	heaved	heaved
dig	dug	dug
	digged	digged
crow	crew	crowed
	crowed	
help	helped	holpen
		helped
hew	hewed	hewn
		hewed
lade	laded	laden
lose	lost	lost, lorn (as in *forlorn*)
melt	melted	molten
		melted
mow	mowed	mown
		mowed
rive	rived	riven
		rived
saw	sawed	sawn
		sawed
shape	shaped	shapen
		shaped
shave	shaved	shaven
		shaved
shew, *or* show	shewed, *or* showed	shewn, shown, *or* shewed, showed
sow	sowed	sown
		sowed
strew	strewed	strewn, strown
		strewed
swell	swelled	swollen
		swelled
wash	washed	washen
		washed

Present.	*Past.*	*Past Participle.*
wax (= to grow)	waxed	waxen waxed
do	did	done
go	[went]	gone

NOTES. *Went*, used as the past tense of *go*, is the past tense of *wend*—as in "to wend one's way."

Crew (from *crow*) is rarely used now, and only of the literal crowing of a cock—*e.g.*, "the cock *crew*." When used of the crowing of babies, etc., the past tense is always *crowed*.

Many of the above forms are now obsolete—*e.g.*, *holpen* ("He hath holpen his servant Israel"), *hoven*, *washen*, *waxen* ("The children of Israel were *waxen* strong"); and some of the past participles are used only as adjectives—*e.g.*, a *molten* image, the *cloven* hoof, a *shaven* head.

Clothe, *have*, and *make* form *clad*, *had*, and *made*, which are contracted from *clothed*, *haved*, and *maked*.

Tight, *straight*, *dight* (adjectives) are weak past participles of *tie*, *stretch*, *deck* (= to *adorn*). *Distraught* is an irregular past participle of *distract*. *Fraught* is sometimes said to be the participle of "to freight," but probably it is not connected with any verb.

"Lie" and "Lay." So much confusion is prevalent concerning these two verbs that a special paragraph seems needful in this connection. We can leave out of consideration *to lie*, meaning *to tell an untruth*; for this verb is of the weak conjugation and perfectly regular, *lie*, *lied*, *lied*.

Examples: "He *lied* like a trooper," "You have *lied* to me more than once."

The confusion arises between *to lay* and *to lie* (meaning *to recline*), because the past tense of *lie* in this sense is *lay*. Let us compare the principal parts of the two verbs.

Present.	*Past.*	*Past. Part.*
lie	lay	lain
lay	laid	laid

To lie is strong and *intransitive*; therefore, it cannot govern an object or be used in the passive voice. *To lay* is weak and *transitive*; therefore it must have an object expressed.

Examples: "He *lay* there for several hours," "I have never *lain* on a softer bed," "That hen *laid* an egg yesterday," "Having *laid* His hands upon them, He blessed them." Of course, we can say either "They *lay* down" or "They *laid themselves* down"; the meaning is practically the same in either sentence, but the verb in the first is intransitive, and in the second transitive (with *themselves* as object).

EXERCISE.

Correct, *if necessary*, the following sentences:

1. I will both lay me down in peace, and sleep.
2. We ought to lay down our lives for the brethren.
3. I am going to lay down.
4. He lied when he said that he had lain his work aside and had laid down all the afternoon.
5. Having lain motionless for some time, I began stealthily to creep along.
6. When he has laid his burden down, he will be a different man.
7. Lay here and rest; lay your head upon this pillow.
8. It has been laid upon me that I ought to go.

By Louis A. Barbé, B.A.

NOUNS AND ADJECTIVES

The Feminine

1. Certain nouns have masculine and feminine forms consisting of wholly different words, as in English. The chief of these are:

Masculine.	*Feminine.*
bélier, ram	*brebis*, ewe
bouc, he-goat	*chèvre*, she-goat
cerf, stag	*biche*, hind
cheval, horse	*jument*, mare
cochon, pig	*truie*, sow
compère, gossip	*commère*, gossip.
coq, cock	*poule*, hen
garçon, boy	*fille*, girl
gendre, son-in-law	*bru*, daughter-in-law
homme, man.	*femme*, woman
jars, gander	*oie*, goose
lièvre, hare	*hase*, doe-hare
mâle, male	*femelle*, female
monsieur, gentleman	*dame*, lady
neveu, nephew	*nièce*, niece
oncle, uncle	*tante*, aunt.
papa, papa	*maman*, mamma
parrain, godfather	*marraine*, godmother
père, father	*mère*, mother
roi, king	*reine*, queen
taureau, bull	*vache*, cow

2. Certain feminine forms retain the masculine stem, but are irregular in their termination:

Masculine.	*Feminine.*
ambassadeur, ambassador	*ambassadrice*, amb- sadr
canard, drake	*cane*, duck
compagnon, companion	*compagne*, companion
devin, soothsayer	*devineresse*, soothsayer
dieu, god	*déesse*, goddess
dindon, turkey	*dinde*, turkey-hen
duc, duke	*duchesse*, duchess
empereur, emperor	*impératrice*, empress
gouverneur, governor	*gouvernante*, governess
héros, hero	*héroine*, heroine
loup, wolf	*louve*, she-wolf
mulet, mule	*mule*, mule
perroquet parrot	*perruche*, parrot
poulain, foal	*pouliche*, filly
serviteur, servant	*servante*, servant

3. **The names of many animals have only one form. In that case, when there is any necessity for indicating the difference of sex, it is done by adding the words *mâle* or *femelle*.**

Formation of the Feminine

Such nouns as have feminine forms follow the same rules as adjectives for the formation of the feminine. These rules are as follow :

1. **To form the feminine of nouns and adjectives add a mute *e* to the masculine : *grand, grande,*** large ; ***petit, petite,*** small ; ***marquis, marquise,*** marquess ; *ami, amie,* friend.

2. If the masculine ends in mute *e* no change takes place : *jeune* (m. and f.), young ; *aimable* (m. and f.), amiable.

Exceptions : The following nouns, ending in mute *e*, form their feminine by changing *e* into *esse* :

âne	ass	*ânesse*
chanoine	canon	*chanoinesse*
comte	count	*comtesse*
druide	druid	*druidesse*
hôte	host	*hôtesse*
maître	master	*maîtresse*
mulâtre	mulatto	*mulâtresse*
nègre	negro	*négresse*
prêtre	priest	*prêtresse*
prince	prince	*princesse*
prophète	prophet	*prophétesse*
tigre	tiger	*tigresse*
traître	traitor	*traîtresse*

When *mulâtre* and *nègre* are used as adjectives they have the same form for both genders.

3. Nouns and adjectives ending in *el, eil, en, ien, on, et* in the masculine, form their feminine by doubling the final consonant and adding mute *e* : *mortel, mortelle,* mortal ; *pareil, pareille,* similar ; *européen, européenne,* European ; *musicien, musicienne,* musician ; *mignon, mignonne,* dainty ; *muet, muette,* mute.

Exceptions : The following adjectives in *et*, instead of doubling the *t* before adding mute *e*, take a grave accent on the *e* that precedes it :

complet	complete	***complète***
incomplet	incomplete	***incomplète***
concret	concrete	***concrète***
discret	discreet	***discrète***
indiscret	indiscreet	***indiscrète***
inquiet	anxious	***inquiète***
replet	corpulent	***replète***
secret	secret	***secrète***

4. **The following adjectives also form their feminine by doubling the final consonant and adding mute *e* :**

bas	low	***basse***
épais	thick	***épaisse***
exprès	express	***expresse***
gentil	pretty	***gentille***
gras	fat	***grasse***
gros	big	***grosse***
las	tired	***lasse***
nul	null	***nulle***
pâlot	palish	***pâlotte***
paysan	peasant	***paysanne***
vieillot	oldish	***vieillotte***

5. The five adjectives, ***beau, nouveau, fou, mou,*** and ***vieux***, which are used only before nouns beginning with a consonant or aspirated ***h***, have a second masculine form, ***bel, nouvel, fol, mol,*** and ***vieil***, which is used before a vowel or silent ***h***. The second masculine form of these adjectives is *not* required in the plural, because there the final *x* or *s* prevents any harshness of sound before a vowel. Thus, the plural form of *beau* and of *bel* is *beaux*. The feminine is got from this second form by doubling the final *l* and adding a mute *e*.

beau, bel	beautiful	*belle*
nouveau, nouvel	new	*nouvelle*
fou, fol	mad	*folle*
mou, mol	soft	*molle*
vieux, vieil	old	*vieille*

6. Nouns and adjectives ending in *er* form their feminine by putting a grave accent on the *e* preceding the *r*, and adding mute *e* : *léger, légère,* light ; *premier, première,* first ; *berger, bergère,* shepherd ; *laitier, laitière,* milkman.

7. The feminine of adjectives ending in *gu* is formed by adding a mute *e* with a diæresis (*ë*): *aigu, aiguë,* sharp ; *ambigu, ambiguë,* ambiguous.

8. The feminine of adjectives ending in *f* changes *f* into *ve*: *vif, vive,* lively; *bref, brève* short; *neuf, neuve,* new.

9. The feminine of adjectives ending in *x* is formed by changing *x* into *se* : *heureux, heureuse,* happy ; *jaloux, jalouse,* jealous.

Exceptions :

doux	*douce*	sweet
faux	*fausse*	false
préfix	*préfixe*	prefixed
roux	*rousse*	red-haired
vieux	*vieille*	old

10. Of the few adjectives ending in *c* the following three form their feminine by changing c into *che* :

blanc	*blanche*	white
franc	*franche*	frank
sec	*sèche*	dry

The others change c into *que* :

caduc	*caduque*	decrepit
public	*publique*	public
turc	*turque*	Turkish

Grec, Greek, retains the c, *grecque* When *franc* means Frankish, its feminine is *franque*.

11 Nouns and adjectives ending in *eur* form their feminine in four different ways :

(*a*) Nouns and adjectives in *eur* derived directly from the present participle of verbs by changing ***ant*** into ***eur***, form their feminine by changing ***eur*** into *euse*: ***trompeur, trompeuse*** deceitful; ***boudeur, boudeuse,*** sulky , ***danseur, danseuse,*** dancer ; ***pêcheur, pêcheuse,*** fisher.

(*b*) **Nouns and adjectives ending in *eur* preceded by *t* (*teur*), in which the *t* belongs to the ending and not to the stem of the word, form their feminine by changing *teur* into *trice*. Many of them have corresponding English forms in tor : *acteur, actrice,* actor : *conducteur, conductrice,* conductor ; *créateur créatrice,* creator ; *exécuteur, exécutrice,* executor. This rule does not** apply to such words as the following, in which the *t* belongs to the stem: *acheteur, acheteuse*, buyer: *menteur, menteuse*, liar; *flatteur, flatteuse*, flatterer; *porteur, porteuse*, bearer

(*c*) Nouns and adjectives ending in *érieur* (= English *erior*), together with the three words *meilleur*, better; *majeur*, major, and *mineur*, minor, form their feminine regularly by the addition of mute *e*: *supérieur, supérieure*, superior; *inférieur, inférieure*, inferior.

(*d*) Some words in *eur*, that may be used both as adjectives and as nouns, form their feminine by changing *eur* into *eresse*. They are:

enchanteur	*enchanteresse*	enchanting
pécheur	*pécheresse*	sinner
vengeur	*vengeresse*	avenger

In legal phraseology *défendeur* and *demandeur*, defendant and plaintiff, have the feminine forms *défenderesse* and *demanderesse*.

The ordinary feminine of *chanteur* is *chanteuse*, but when applied to a professional singer it is *cantatrice*. *Chasseur*, hunter, if ever used in the feminine, has both *chasseuse* and *chasseresse*. The latter form is poetical, and occurs almost exclusively in connection with Diana and her nymphs. *Imposteur* has no feminine form as a noun, and is never used in the feminine as an adjective.

(*e*) The following forms do not come under any special rule:

long	*longue*	long
oblong	*oblongue*	oblong
bénin	*bénigne*	benign
malin	*maligne*	malicious (sly)
coi	*coite*	still (snug)
favori	*favorite*	favourite
frais	*fraîche*	fresh

(*f*) *Tiers*, an old form of the ordinal numeral, third (now *troisième*), is still used in a few expressions, and has *tierce* as its feminine—*e.g.*, *une tierce personne*, a third party.

Hébreue, as the feminine of *hébreu*, Jewish, is seldom used; it is only applicable to persons, and is practically superseded by *juive*, Jewish. In any other case, the feminine form *hébraïque* is used—*e.g.*, *la langue hébraïque*, the Hebrew language.

When the feminine form of a noun or of an adjective requires a grave accent it is for the purpose of preventing two mute syllables, that is, two syllables ending with a mute *e*, from coming together, thus: *sec, sè-che*; *bref brè-ve*; *berger, bergè-re*; *secret, secrè-te*.

In *exprès* the grave accent of the masculine form disappears in the feminine because the open sound which it gives the *e* is obtained by the addition of *se*, and it consequently becomes superfluous.

The diæresis on the mute *e* of such feminine forms as *aiguë* indicates that the sound of the *u* is to be retained. Without it the *g* alone would be heard as in the English word "egg."

The addition of mute *e* to a noun or adjective ending with a consonant causes the final, which is frequently silent in the masculine, to be distinctly heard, thus *savan(t)*, *savant(e)*, learned. In the case of a vowel ending, the mute *e* slightly lengthens the vowel sound, thus: *joli, jolie*, pretty; *ami, amie*, friend

The plural of the feminine forms is formed like that of the masculine by adding *s*: *Les poires sont bonnes*, the pears are good.

Adjectives agree in gender and number with the nouns which they qualify, thus: *l'arbre est haut, les arbres sont hauts*; *la belle fleur, les belles fleurs*.

GERMAN

Continued from page 750

By P. G. Konody and Dr. Osten

Gender of Nouns

VII. In German the following are of MASCULINE GENDER:

(*a*) the substantives, denoting male persons and animals, and many inanimate objects;

(*b*) the names of the seasons, months, days, and stones;

(*c*) all nouns ending in m, except those of Latin origin.

EXAMPLES. (*a*) der Sohn, son: der Bruder, brother; der Onkel, uncle; der Knabe, boy; der Greis, old man (greybeard); der Löwe, lion; der Tiger, tiger; der Bär, bear; der Wolf, wolf; der Adler, eagle; der Falke, falcon; der Sperling, sparrow; der Berg, mountain; der Fluſs, river; der Baum, tree; der Wind, wind.

(*b*) der Frühling, Spring; der Sommer, Summer; der Herbſt, Autumn; der Winter, Winter; der Monat, month; Jänner (also Januar), January; der Februar, February; der März, March; der April, April; der Mai, May; der Juni, June; der Juli, July; der Auguſt, August; der September, September; der Oktober, October; der November, November; der Dezember, December; but das Jahr (*n.*), the year; die Woche (*f.*), the week; der Tag, the day; and die Nacht, the night; der Montag, Monday; der Dienſtag, Tuesday; der Mittwoch, Donnerſtag, Freitag, Samſtag (or Sonnabend), Sonntag, (Wednesday, Thursday, Friday, Saturday, Sunday);—der Stein, stone; der Diamant, diamond; der Rubin, ruby; der Smaragd, emerald; der Kieſel, pebble; der Marmor, marble; der Granit, granite.

(*c*) der Sturm, storm; der Schwarm, swarm; der Arm, arm; der Wurm, worm; der Lärm, noise; der Atem (or Odem), breath.

EXCEPTIONS: die Form, form; die Farm, farm; das Publikum, the public; and other derivations from the Latin.

There are of course many other nouns of masculine gender, but there are so many exceptions to the rules which could be formed, that it is simpler to follow the practice of learning each of these nouns with its definite article.

Thus, *e.g.*, der Schall, sound; but das Metall, metal; and die Nachtigall, nightingale; der Nebel, fog; but die Nadel, needle; and die Fabel, fable; der Ring, ring; but das Ding, thing; der Magen, stomach; but das Eiſen, iron; der Hafer, oats; but die Mauer, wall; and das Fenſter, window

1. The grammatical and natural gender do not always coincide in German. Thus the diminutives of masculine and feminine nouns are neuter, and are formed by the suffixes ⸗chen or lein: der Vater — das Väterchen (or Väterlein), little father; der Mann — das Männchen (or Männlein), little man; die Mutter — das Mütterchen (or Mütterlein), little mother; die Tochter — das Töchterchen (or Töchterlein), little daughter.

NOTE. das Weib, woman; das Fräulein, young lady; das Mädchen, girl. Die Waiſe, orphan; der Säugling, baby or infant; and das Kind, child; are used for both sexes.

Gender of Adjectives

VIII. The ADJECTIVE agrees (*a*) in gender, number and case with the substantive which it precedes, (*Attributive Adjective*). When used as *Predicate* (*b*), that is to say, after the auxiliary verbs ſein and werden, it remains unaltered.

EXAMPLES: fleißig, diligent; gut, good; ſchlecht, bad; ſchön, beautiful; häßlich, ugly; reich, rich; arm, poor; hoch, high; ſtark, strong; ſchwach, weak; kurz, short; lang, long; rot, red; grün, green; weiß, white; blau, blue; gelb, yellow; ſchwarz, black; grau, grey; braun, brown; kalt, cold; warm, warm; lau, tepid: heiß, hot: naſs, wet; trocken, dry

(*b*) der Knabe iſt fleißig, the boy is diligent;
die Frau iſt fleißig, the woman is diligent;
das Kind iſt fleißig, the child is diligent.

(Examples for (*a*) will follow in chapter dealing with the declension of the adjective.)

The Interrogative

IX. The DIRECT QUESTION is formed by placing the verb with the personal termination at the beginning of the sentence. Thus in the sentence: ich habe geſchlafen, (I have slept); habe is the verb with the personal termination, and the form of question would be: Habe ich geſchlafen?

EXAMPLES:

Ich bin arm,
I am poor,
Bin ich arm?
Am I poor?
Wir ſind reich,
We are rich,
Sind wir reich?
Are we rich?
Die Frau hat ein Kind,
The woman has a child,
Hat die Frau ein Kind?
Has the woman a child?

1. Under no circumstances is the verb thun (to do) to be used in questions, as in English. Thus, Do you speak German? is *never* translated: Thun Sie deutſch ſprechen? but always: Sprechen Sie deutſch? (Speak you German?).

Did you speak German? is always rendered as: Spoke you German? (Sprachen Sie deutſch?).

Conjugations of Verbs

X. The CONJUGATION OF THE VERB is either weak, strong, or mixed. The majority of German verbs take the weak conjugation.

1. The distinguishing feature of the weak and strong conjugations is the formation of the *Imperfect*, the former by suffixes alone, and the latter by change of the stem vowel. The weak verbs *never* modify the stem vowel.
2. Inflections of weak verbs in the Present Tense:

Indicative:

⸗e	ich lob⸗e	I praise.	
⸗eſt or ⸗ſt	du lob(e)⸗ſt	thou praisest.	
⸗et or ⸗t	er lob(e)⸗t	he praises.	
⸗en	wir lob⸗en	we	
⸗et or ⸗t	ihr lob(e)⸗t	you	praise.
⸗en	ſie lob⸗en	they	

Subjunctive:

⸗e	ich lob⸗e	I praise.	
⸗eſt	du lob⸗eſt	thou praisest.	
⸗e	er lob⸗e	he praises.	
⸗en	wir lob⸗en	we	
⸗et	ihr lob⸗et	you	praise
⸗en	ſie lob⸗en	they	

3. The -e of the inflections in the 2*nd* and 3*rd* *pers. sing.* and 2*nd* *pers. plur.* is generally dropped in the *Indicative*, but retained in the *Subjunctive* of verbs with stems ending in -d, -ſt, -t, -th; (red-en, to speak; röſt-en, to roast; läut-en, to ring; erröth-en, to blush; etc.), and wherever its omission would result in harsh or difficult pronounciation, for instance, in the 2*nd* *pers. sing. indic.* of verbs with stems ending in hissing sounds: -ſ, -ſſ, ſch, z; like: ſpeis-en, to dine or eat; haſſ-en, to hate; lauſch-en, to listen; ſchnalz-en, to smack one's tongue; etc. — ſpeiſeſt, haſſeſt, etc.
4. Verbs ending in -eln cast off the e of this suffix in the 1*st* *pers. sing: indic.*, for similar reasons of euphony: handeln, to act, to bargain, ich hand(e)l-e; lächeln, to smile. ich läch(e)l-e. The e is, however, retained in the 2*nd* and 3*rd* *pers. sing.*: du handel-ſt, er lächel-t, etc.

Declension of Pronouns

XI. THE DECLENSION OF THE PERSONAL PRONOUNS. (The numbers 1—4 indicate the four cases.)

	Singular 1st Person		*2nd Person*		*3rd Person*					
1.	ich	I	du	thou	er	he	ſie	she	es	it
2.	meiner (mein)	of me	deiner (dein)	of thee	ſeiner (ſein)	of him	ihrer	of her	ſeiner (ſein)	of it
3.	mir	to me	dir	to thee	ihm	to him	ihr	to her	ihm	to it
4.	mich	me	dich	thee	ihn	him	ſie	her	es	it
	Plural		*Plural*		*Plural (for all 3 genders)*					
1.	wir	we	ihr	you	ſie	they				
2.	unſer	of us	euer	of you	ihrer	of them				
3.	uns	to us	euch	to you	ihnen	to them				
4.	uns	us	euch	you	ſie	them				

The bracketed form of the *2nd pers. sing.*, mein, dein, ſein, is sometimes used in poetry, proverbs, and exalted speech.

EXAMINATION PAPER III.

1. Which German nouns have the masculine gender ?
2. What is the difference between the adjective used as a predicate, and the adjective when it precedes the noun ?
3. What is the distinguishing feature of the weak and strong conjugation ?
4. What is the gender of diminutives ?
5. In what way does the German form of question differ from the English ?
6. Which conjugation (strong, weak, or mixed) is taken by most German verbs ?
7. Do the weak verbs ever modify the stem vowel ?
8. What is the peculiarity of the conjugation of the present tense of verbs ending in -eln ?
9. What is the peculiarity of the conjugation of the present tense of verbs with stems ending in -d, -ſt, ,t and -th ?

EXERCISE 1. Insert in the dotted places the auxiliary verbs haben (to have) and werden (to become, to get), and the articles.

Ich .... Vater und .... Mutter. Du .....
I have a father and a mother. Thou growest

ſtark. Er ... . Lehrer. ... Frau ... .
strong. He has a teacher. The woman has a

Mann. .... Kind .... fleißig. ....
husband. The child becomes diligent. The

Mütter .... Kinder. ... Männer .... Fiſch.
mothers have children. The men have a fish.

Ihr .... Onkel; ſie .... Sohn.
You have a uncle; they have a son.

.... Mädchen ..... ſchön.
The girl becomes (is getting) beautiful.

.... Kinder .... fleißig.
The children become diligent.

EXERCISE 2. Insert the definite article.

.... Bruder .... Mutter iſt... Onkel ... Sohnes.
The brother of the mother is the uncle of the son.

.... Löwe iſt ſtark. .... Berg iſt hoch.
The lion is strong. The mountain is high.

.... Auguſt iſt warm. .... Frühling iſt ſchön.
[The] August is warm. Spring is beautiful.

.... Tage werden kurz. .... Südwind iſt warm.
The days become short. The south wind is warm.

.... Rubin iſt rot, ... Smaragd grün und
The ruby is red, the emerald green, and

.... Diamant weiß. .... Stall iſt trocken.
the diamond white. The stable is dry.

... Hafer iſt naß. .... Metall iſt weiß.
The oats are [is] wet. The metal is white.

..... Säbel iſt ſcharf. ..... Nadel iſt gut.
The sword is sharp. The needle is good.

.... Wurm iſt ſchwach. .... Arm iſt ſtark.
The worm is weak. The arm is strong.

.... Weib iſt .... Mütterchen .... Mädchens.
The woman is the [*dimin.*] mother of the girl.

.... Männlein is .... Vater .... Fräuleins.
The [*dimin.*] man is the father of the young lady.

.... Knabe iſt .... Waiſe.
The boy is an orphan.

.... Säugling iſt .... Mädchen.
The baby is a girl.

EXERCISE 3. Insert the conjugational terminations to the stems of the verbs.

Ich arbeit... fleißig. Der Schüler lern...
I work diligently. The scholar (pupil) learns.

Wir ſchreib... Briefe. Du arbeit... Ihr lob...
We write letters. Thou workest. You praise

die Kinder. Der Lehrer lob... den Schüler.
the children. The teacher praises the pupil.

Sie lieb... die Kinder. Sie lieb... die Kinder;
They love the children. You love the children;

ſie lieb... die Kinder.
she loves the children.

EXERCISE 4. Put the sentences of Exercise 3 into the form of questions.

EXERCISE 5. Translate the following English questions into German without using the German equivalent of the auxiliary verb "to do," and translate the German questions into correct English.

Do you smoke ? Do you love the child ?
Does he work diligently ? Dost thou learn ?
Do they drink ?

Schreibſt du einen Brief? Lobt der Lehrer den Schüler? Lieben die Mütter die Kinder? Liebet ihr den Vater? Rauchen wir? Arbeiten Sie? Arbeiten ſie? Arbeitet ſie?

EXERCISE 6. Insert the corresponding cases of the personal pronouns.

.... ſehe* ....; .... lobſt ....; .... liebt ....
I see thee; thou praisest me; he loves her

und .... liebt ....; .... gab .... und .... gab
and she loves him; she gave him and he gave

.... einen Ring; .... liebe ....; .... ſagt* ....;
her a ring; I love it; he tells me;

.... lob-et ....; .... lob-en ....; .... lieb-en ....;
you praise us; you praise us; we love you;

.... ſag-e ....; .... ſag-e ....
I tell you; I tell thee.

Gedenke* ... ...
Remember [of] me, us, you, her, him, it, them.

---

* ſeh-en, to see; ſag-en, to tell; gedenk-en, to remember. Gedenken governs the genitive.

Continued

TRANSPOSITION

Transposing at Sight and on Paper. Changing Accidentals. Reading by Intervals. Score Reading. Transposing Instruments

Continued from page 925

By ALGERNON ROSE

THE art of transposition is not modern. In the days of Greece, Claudius Ptolemy transposed the "Hymn of Nemesis" from the old high pitch of the scale of Alypius a fourth lower. But the Greek system of musical notation was different to ours, although in certain respects analogous, because the modern tone-system has been partly evolved through the old ecclesiastical modes.

Ancient Methods of Transposition. In old missals dated A.D. 1300–1400, transposition from one mode to another was regulated by the distinctive colouring of certain of the notes. Coming to later times, Loulié, a French musician, wrote an ingenious book in 1698 published by Estienne Roger, of Amsterdam. In this the author explains the nature of transposition, and sets forth a method of reducing music into any of the keys denoted, either by the acute or grave signatures, and translating them back again into the original, or radical, keys.

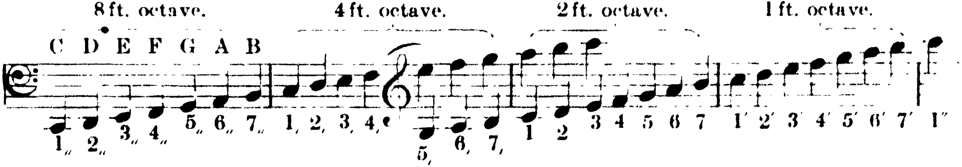
Definition. In music, the word transposition has several meanings, but its usual signification is the rendering of a composition in another key than that in which it is written. This is done either by copying out, singing, or playing a piece by altering the pitch equally from start to finish —whether a semitone, tone, major or minor third, higher or lower, as may be desired. [See THEORY OF MUSIC.]

Transposing on Paper. To alter the key in which a piece is composed by translating it into a different scale is easy enough on paper. Such pen-and-ink exercises should always supplement a student's practical studies. In order to master his instrument, he should practise each study in as many different keys as possible. The most economical way of getting the notation for this is to transpose the exercise on paper.

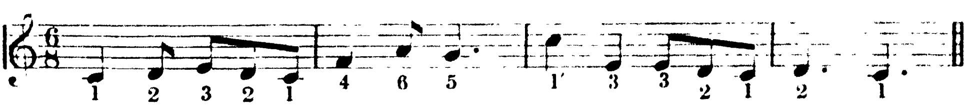
The first point is to find the new tonic, or keynote. After this has been done, alter the key signature accordingly. The rest in a straightforward diatonic composition is a matter of carefully copying out each note at an equal distance above or below the original.

Transposing Melodies. Taking the notes of the three centre octaves of a piano—of which the C just over the lock gives the middle, or first ledger line C beneath the G clef—substitute the numbers 1 to 7 for the letters C to B inclusive. Employ ordinary numerals for the centre, or 2 ft., octave. Add an acute accent to each figure upwards in the next, or 1 ft., octave, two accents for the 6 in. treble octave, and three accents for the 3 in. high treble octave. To discriminate the lower notes, attach a single comma below each number in the 4 ft. octave, two commas to each in the 8 ft. bass octave, and three in the 16 ft. low bass octave.

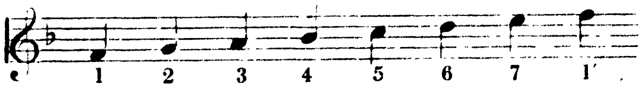
Intervals. Such numbers represent intervals which are alike in all keys although the names, or letters, of the notes alter. Number the scale of C major thus:



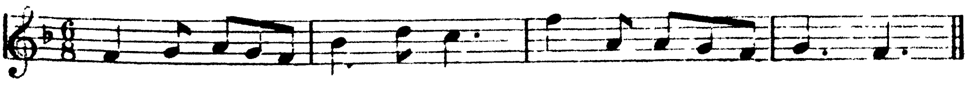
Suppose the melody is as follows:



It is required to be transposed, say, a fourth. A fourth above C is F. F major has one flat—B. Beginning at F, write out and number a similar scale with the one flat signature, thus:



The student, who may know nothing of music, by taking these numbers and writing the notes in their new places, will be able to transpose the melody correctly from C to F, thus:



The first essential, therefore, is to recognise quickly the distance of each note from the first, or tonic, of the scale. By inscribing simple exercises of one octave, and transposing the notes systematically into all the keys, the beginner will soon become accustomed to reckon with the eye the proper position for each note, and will then be able to dispense with the figures.

Obviously, the transposition on paper of any diatonic melody presents no difficulty to the scribe, since all that has to be done is to calculate the higher or lower position needed for each note

Transposing at Sight. It is, however, not infrequently the case that a pianist or organist is required to transpose a piece of music at sight to suit a singer. The task is then more arduous. But it has to be done. For that reason, candidates for examination for the Incorporated Society of Musicians, the Associated Board, the Royal College of Organists, and other institutions, are required to show reasonable ability in this respect.

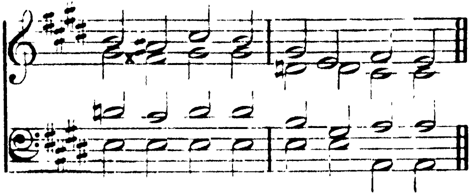
Concert Pitch. When, in 1896, the London Philharmonic Society discarded the high military pitch, and came into tune with the music of the Continent by lowering the British standard to the note represented by A, giving 439 entire vibrations per second when tested at a concert-room temperature of '68 degrees Fahrenheit, the change was widely welcomed by singers, whose voices were unnecessarily strained by the military band pitch. But, owing to the great expense of re-tuning and re-voicing large organs, it happens to-day that when musicians reinforce a church choir with wind instruments at the new pitch, or if the organ has been altered and bandsmen bring in instruments at the old pitch, the organist is forced to transpose at sight a semitone lower or higher, as the case may be.

He cannot, like the guitarist, alter the pitch of his instrument by putting on a capotasto, neither can he adopt the device of the violinist called the scordatura, and thereby deviate from the ordinary tuning as required.

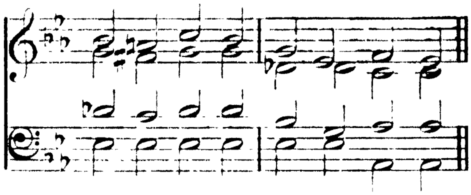
Extreme Keys. Usually, all that is wanted is to transpose a semitone up or down. In this case the task is comparatively easy. Taking C major and A minor as the normal scales of our musical system, all the pianist or organist has to do when required to raise the pitch half a tone is to change mentally the signature to C sharp major or A sharp minor. Should the sounds have to be lowered, the transposer imagines that the signature is C flat major or A flat minor. It may be argued that extreme keys, bristling with sharps or flats, are very difficult. That depends on whether the student has, or has not, taken the trouble to accustom himself to them. He will now perceive, in a way which may not have been before apparent, why it is advantageous to practise as often as possible scales which have many accidentals.

Changing Accidentals. To understand this method of transposition, it is better not to begin with C or A. Take a hymn in the key, say, of E major, like Barnby's "St. Hilda." To transpose it down to E flat major, obliterate from the mind the printed signature of four sharps. In their place think of the three flats B, E, and A. Then play the music as written, except when an accidental occurs. As the key is lowered half a tone, whenever a natural arrives in the music the mind must transform that natural into a flat. When a sharp comes along, imagine that it is a natural. In the same way, a double sharp must convert itself into a single sharp, and a single flat into a double flat. We have only space here to quote the 5th line:

"St. Hilda." BARNBY.



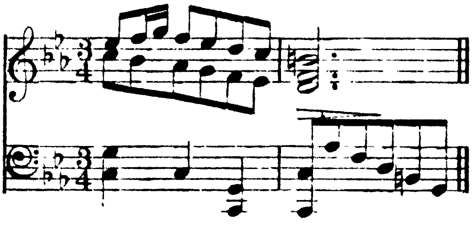
Transposed a half-tone lower.



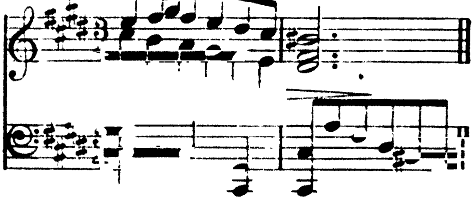
On the other hand, if the hymn chosen is in E flat major, and has to be transposed a semitone upwards, the mental process is reversed.

Obliterate from the mind the signature of the three flats. In their places substitute the four sharps F, C, G, and D. Wherever a natural occurs on the printed page, it must become a sharp. A flat changes into a natural, a sharp into a double sharp, and a double flat dissolves into a single flat.

"St. Matthew." BACH.



Transposed up a half-tone.

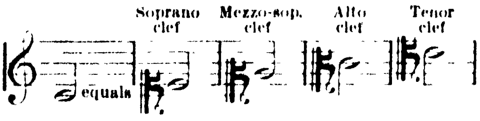


Reading by Intervals. It is when we come to transposition at intervals of a third, fourth, fifth, and so on, higher or lower, that the task of the reader increases in difficulty. On such occasions the player must be either well acquainted with the rules of harmony or familiar with the piece before he attempts to transpose. The eye then reads by intervals rather than by actual notes. Infant prodigies at the piano can go to the instrument and play by ear melodies they have heard with appropriate harmonies. Usually they are capable of playing the tune in any key they fancy. This gift comes naturally to them. It is called "playing by ear." The child cannot analyse the way in which the result is obtained. But the moral of this is that the younger the student happens to be, the better is his chance of becoming a skilful transposer if he gives his mind, while it is yet plastic, to this useful branch of musical study.

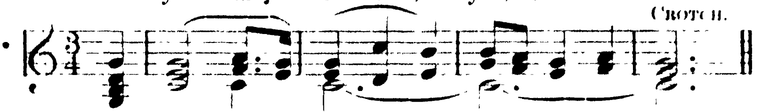
In transposing to a key more than a semitone higher or lower, the player who has studied harmony does not trust to chance. He takes his cue from the lowest note. From that he builds up the superstructure grammatically. To do this requires, with most players, long and constant practice. A privileged minority seems to develop the knack by instinct. With such players, as in the case of that ideal accompanist Mr. Henry Bird, transposition is always made artistically. The best part of the pianoforte is, or should be, its middle register. To transpose a piece a fifth, sixth, or seventh lower than it is written may entirely alter the character of an accompaniment, and cause it to sound lugubrious in a way never intended.

Retaining the Composer's Intention. This is one of the objections musicians have to mechanically transposing keyboards, the main one, of course, being that they cannot take such contrivances about with them like fiddles. By occasionally altering the disposition of the written notes in arpeggios or chords, the accomplished accompanist contrives to enhance the effect of the voice, and communicate the nature of the original composition, thus retaining the intention of the composer. The class of musician most accustomed to transposing at sight is the orchestral player. For him it is less difficult than the pianist. He reads from only one stave, and usually a succession of single notes.

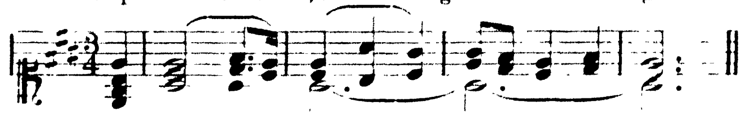
The "C" Clefs. The pianist ordinarily confines his attention to the treble and bass clefs. But the studious instrumentalist who has made himself conversant with the various C clefs is able to use these when transposing at sight, and thus save himself all trouble of calculating intervals. In the days of Purcell these extra clefs were common in vocal music. With the exception of the tenor clef, they are now seldom used. Instead of C being indicated on the first ledger line below the staff, as it is when our G, or treble, clef is used, the soprano clef places that note on the first line, the mezzo-soprano clef causes it to rest on the second line, the alto on the third line, and the tenor on the fourth line, thus:



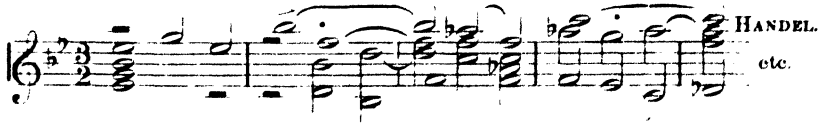
The Soprano Clef. The music transposes itself automatically by substituting the soprano C mentally for the treble G clef, and playing the notes as written, remembering the requisite accidentals for the new signature. Read in this manner, the substituted clef causes the music to sound a third lower or a sixth higher. Thus, if the original is in C major, it is now heard in the key of A major. Therefore, every F, C, and G must become sharp.



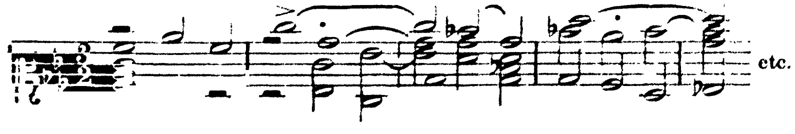
The same notes transposed a third lower, or a sixth higher if "8vo" is imagined above them.



The Mezzo-soprano. When the mezzo-soprano C clef mentally supersedes the G treble clef, and the signature of the new key is borne in mind, the player is able to render the printed notes at once a fifth lower or a fourth higher. Consequently, if the original is in C, the key will now be F, with one flat—B. If in B flat the transposition will be to E flat, thus:

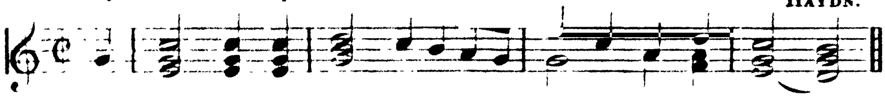


The same notes transposed a fifth lower, or fourth higher if an "8vo" is imagined above them.

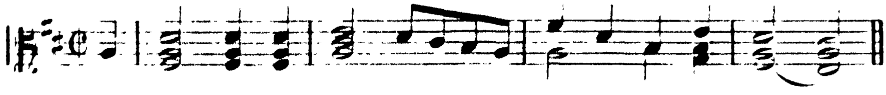


The Alto. Reading in the alto in place of the G clef, the player transposes a seventh lower or a second higher. A piece written in C major, but taken in the alto clef, will thus sound in D major, with two sharps—F and C.

HAYDN.

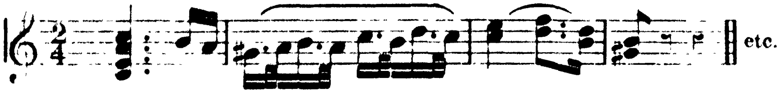


Same notes transposed a seventh lower, or second higher if an "8vo" is imagined above them.

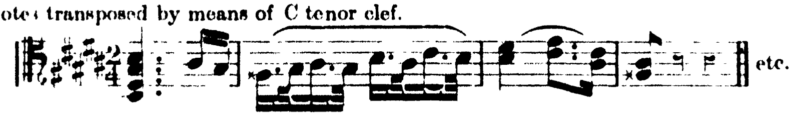


The Tenor. In the same way, the player can transpose music written in the G clef a ninth lower by reading it in the tenor clef, so that a piece in C major played in the tenor clef (giving 2 ft. C on its fourth line) will sound in the key of B, with five sharps—F, C, G, D, and A; in other words—irrespective of octave pitch—a second lower or a seventh higher:

BEETHOVEN.



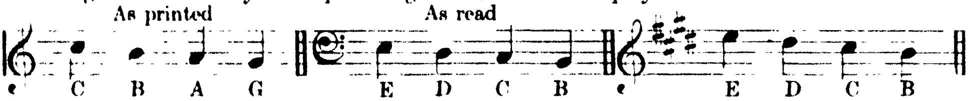
Same notes transposed by means of C tenor clef.



So here we have a ready method of transposition of a third, fifth, seventh, and ninth without the trouble of calculating intervals.

The Bass. But the resources of the instrumentalist are not yet exhausted. If he obliterates the G clef and puts in its place the F, or bass, he lowers the tone a third. But he must then read the sounds a double octave higher than they are written. Supposing the key of the original to be C major, the note sounded will now be in A, with three sharps—F, C, and G.

Having affixed mentally the requisite signature, the notes if played in treble clef would read:



The intelligent student will not lack employment, no matter what instrument he takes up, if he translates systematically the exercises he practises into different keys by means of the various C clefs. When reading the notes with any C clef, the sound can be also transposed, either up or down a semitone, by making mentally a further variation in the signature, in the manner already explained. But this must not be attempted before the student has accustomed himself to reading various exercises in the old vocal clefs and the bass.

Score Reading. The student who neglects to make himself acquainted with transposition will never become proficient in reading an orchestral score. To comprehend an old vocal score where the various C clefs are used, the mental process indicated for translating the sound from the G into the C clefs is, of course, reversed by the beginner, in the same way that an English schoolboy learning French at first slowly translates every French word into its English equivalent before understanding it.

A Full Score. If we take a modern full score, we may find some 30 different parts, ranged one above the other. A non-musician, accustomed to read a single line of letterpress from left to right, regards such notation as hopelessly complicated. Yet it is far superior to his own. It conveys not only the exact rhythm and speed at which every syllable should be read, but also the mental mood in which it must be received. Moreover, musical notation has the gift of brevity. The longest sentence penned can be portrayed vertically in a single sustained chord. If we examine the opening page of a full score, it will be observed that only certain instruments such as the violin, trombones, the oboe and bassoon in C, the harp and organ, play the notes as written. These instruments are called "non-transposing."

Transposing Instruments. On the other hand, the student will observe that the clarionet in A sounds a minor third lower than the printed notes; that the trumpet in E flat expresses itself a minor third higher, and that the horn in D utters its sound a seventh lower. In military scoring there are many such complications. The modern composer, anxious to startle, is, of course, at liberty to avail himself of any and every tone-colour his fancy dictates.

MINIATURE PAINTING

Pastel Work. Miniatures. Choice of the Ivory. The Early Miniature Painters. "Spacing." Framing. Deterioration in Modern Work

By P. G. KONODY

Drawing in Pastel. The nature of the material used for this work—that is to say, of coloured chalks—immediately suggests the limitations of pastel work. Chalk, whether black or coloured, is a *drawing* material, and to use pastel colours in imitation of oil paint is therefore a misapplication of the medium. They should be used for sketching, especially on tinted papers; they should be lightly and daintily handled, and should suggest rather than express. It is impossible to get any degree of transparency into a thick layer of pastel chalk. A sky, for example, thickly smeared over with the lightest blues or greys will invariably appear heavy and leaden. The happiest effects, either in landscape or in portraiture, or, in fact, in any other class of subject, are achieved, if the paper itself supplies the visible ground of the drawing and the chalks are put on in slight, sketchy touches.

What to Avoid. No *pictorial* effects should ever be attempted. Whistler's use of pastel chalks may be quoted as an ideal instance of appropriate treatment. Many of these have been reproduced in excellent facsimile in the "Studio," and in a special portfolio published by the same magazine. Pastel drawing bears about the same relation to painting in oils or water-colours as etching does to mezzotint or line engraving. When the etcher ceases to use his needle in a free, sketchy manner, and makes it serve for the laboured, mechanical interpretation in black and white of a painting, he has overstepped the natural limitations of his medium, and his work ceases to be art; it becomes mere craftsmanship. And so it is with the use of pastel in imitation of oil paint. It lends itself more than any other medium to the rapid expression of an artist's individuality, and for this very reason it is useless to advise the student how to manipulate this material. If he has anything to express, and if he realises the limitations of pastel, and its dainty charm within these limitations, he will soon feel at home in using it.

Though pastel colours are permanent, no reliable method has yet been discovered of fixing them to the paper, and pastel drawings have therefore to be handled with the utmost care lest the brittle chalks should rub off or crumble away. The best way of preserving such drawings is between two sheets of glass. Tinted paper is preferable to white, and ordinary brown packing-paper, not too dark in shade, is an ideal ground for such work. The drawing-paper should be neither very rough nor very smooth, as in both cases the powdery nature of the chalks makes it impossible to get a satisfactory result.

The Story of the Miniature. As conceived by the vast majority of modern workers, miniature painting is a comparatively easy method of using photographic truth and the innate qualities of ivory—its transparency and warm tone—to obtain pleasing results in small portraiture. At the time of the great masters of this art, from Holbein to Cosway and Engleheart, it was the art of painting noble and beautiful portraits of exquisite quality on a very small scale. Their miniatures are small only in size, but grand in conception, like fine life-size portraits. The early miniature painters—Holbein, Cooper, Oliver, Hilliard, and others—worked on parchment and paper, and were, above all, masterly draughtsmen, whose portraits were drawn with wonderful precision, and were full of life and character. Cosway, too, did beautiful drawings on paper, but he recognised the charm of the effects that could be obtained on an ivory basis, and in his admirable work created a delightful convention, graceful and dainty, but rather shallow, which, in the hands of feeble imitators, has proved the ruin of the art.

The student who wishes to take up miniature painting cannot be too emphatically advised not to touch ivory until he is able to draw a good miniature on paper. It is the best and only training that can be recommended, and if he has the solid basis of knowledge and firm draughtsmanship, which can only be thus acquired, he will soon learn the comparatively easy trick of working on ivory, which, of course, requires a different technique. Miniatures on paper are nothing but water-colour drawings on a very small scale, so that no further explanation is here needed.

How to Select the Ivory. In working on ivory, the first consideration is the choice of the material, in which one cannot be too careful. Ivory for this purpose can be bought ready for use at most artists' material dealers. The piece chosen should be as clear as possible—that is to say, one should endeavour to find one free of grain and ribs, especially in the centre, where the face would naturally be placed in the picture. As regards colour, the natural tint—a pale cream—is preferable to the bleached and dead-white ivory, though the coldness of the latter can be counteracted by yellow paper behind the semi-transparent ivory, which produces approximately a natural effect.

A very small, light drawing-board should be used, on which the ivory is fixed by pins. These pins are, of course, not put *through* the ivory, but along the margin, so that the little plaque is held down firmly by the heads of the drawing-pins. Four pins, one at each corner,

By Oliver

By Hilliard

should be sufficient. A piece of clean paper should be between the board and the ivory, as otherwise the grain and inequalities of the board would show through. If the ivory is not quite firmly fixed to the board, it will curl up directly the wet point of the brush touches it, which would make it impossible to work on.

Before working on the ivory, it is advisable to make a rough sketch of the portrait on paper, so as to get the approximate "spacing" of the picture. Then begin to draw the portrait very carefully with pale water-colour: light red is useful for the face, but, in any case colour which can be ultimately part of the miniature itself should be chosen. Pencil cannot be used, as it will show through any paint laid over it, and, moreover, it makes the ivory black and smudgy, and cannot subsequently be removed. It is better, of course, to keep the colour rather cold at first, and to leave the warmest tints for the very last touches, as the warm colours — such as any of the madders, burnt and raw sienna, and even

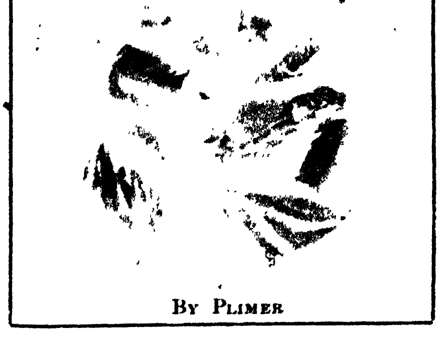
too much yellow ochre—cannot be reduced afterwards by cold tints. They will always show through, whereas the greys can be quickly and easily relieved by the addition of a tint of yellow and brown, which will give a brilliant effect. If grey tints are put on warm shadows, the colour becomes dead and leaden.

Now proceed to build up the portrait gradually, always working over the whole surface, and bringing the *entire head* nearer completion with every sitting. Think only of the modelling, outline, and colour. The stippling necessary for the finish of the miniature will come naturally, for ivory has so slippery and difficult a surface that, however carefully the tones are laid on, there are sure to be some inequalities which can only be removed by stippling. Only when the portrait is finished—that is to say, when the colour has the necessary strength, and when the features are clearly drawn and sufficiently modelled—should stippling be resorted to as a means of sweetening the tones, and giving the velvety texture of skin which is found in the works of masters, and which is needed for work on so small a scale. But a broad style is by no means incompatible with miniature painting.



By Plimer

Modern Miniatures. Almost the worst faults of the modern miniature painter are slovenliness and lack of drawing. The student will do well to avoid modern miniatures altogether. There is practically nothing to be learnt from them. It is a regrettable fact that many of those who call themselves miniature painters have only taken to this form of painting because they have found themselves unable to succeed with any other medium ; to paint a bad miniature is the easiest thing in the world. Study the perfect drawing and strength of the old miniaturists. These and your own model will be all you need to study. Do not work too long at a time, as it is impossible to keep one's eye fresh for such minute work longer than two or three hours at the most.

How to Cut and Prepare the Ivory. An oval shape is usually preferred for portrait miniatures, but the ivory plaques are sold in square pieces. It is, therefore, necessary to cut the finished miniature to the required shape. This is best left to the frame-maker, or to the dealer who supplies the ivory ; for the cutting is a difficult matter, and the first few attempts usually end in the miniature's splitting right across in the direction of the grain.

It is, therefore, best to practise on waste pieces in order to save the material. Very sharp scissors must be used, and it is always better to cut a little outside the actual edge of the picture, as the frame will very slightly overlap the surface. In framing, it is again necessary to have a clear piece of paper behind the painting, and it is usual to back the miniature with several pieces of paper or card, to make the velvet back fit tightly against the ivory.

SCOTLAND

The Orkneys and Shetlands. The Hebrides. The Highlands. Glenmore. The Lowlands. Scottish Coalfields. The Southern Uplands

By Dr. A. J. HERBERTSON, M.A. and F. D. HERBERTSON, B.A.

EACH region of the British Isles has its own character—inland or maritime, highland or lowland, agricultural, pastoral, or manufacturing, and each must be briefly described.

The Scottish Islands. In the Orkneys and Shetlands we are on the fringe of inhabited Britain, among a people mainly Scandinavian. Both groups number scores of islands, most of which are uninhabited. In the Shetlands, Mainland is the largest island; it is over 50 miles long, but so intersected by the sea that no place is more than four miles inland. Lerwick is the chief town. In all the islands the shores are wild and rocky, and the interior is a bleak, treeless moorland, feeding cattle, sheep, and small ponies. The climate is almost too wet and cool for agriculture, but some barley, oats, and potatoes are grown. Nearly every man is a fisherman, the herring and whale fisheries being very important. In the long winter nights the women knit fine shawls of the soft island wool for export. Life in the Orkneys is very similar to that in the Shetlands. A good deal of barley is grown, from which whisky is made. Pomona is the largest island, and Kirkwall the largest town.

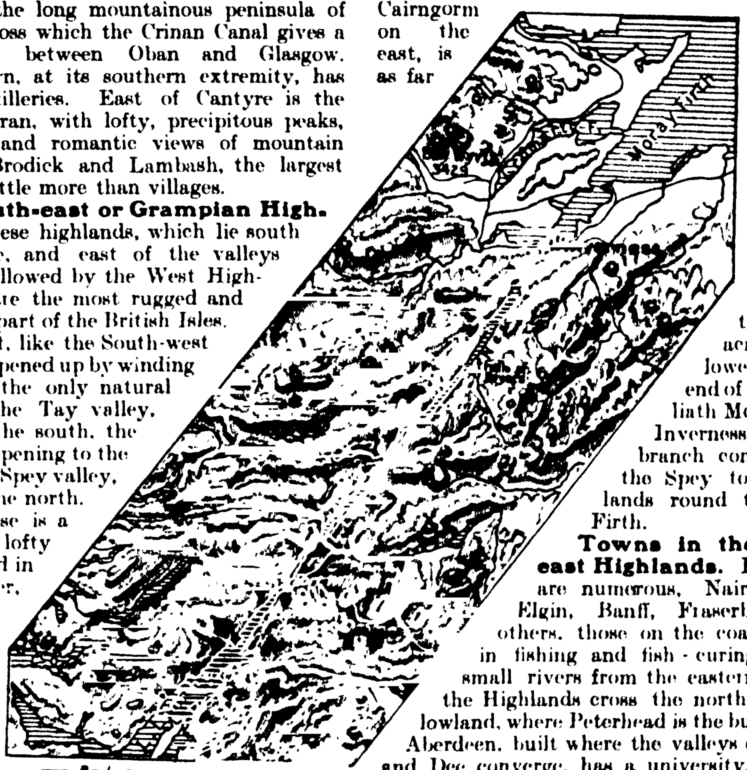
The Hebrides, off the west coast, are divided into the Outer Hebrides, of which the largest is Lewis, and the Inner Hebrides, with Skye in the north, Mull in the centre, Islay in the south, as well as many smaller islands. Surrounded by stormy seas, and shut in by difficult coasts, with fierce currents running between the islands, it is natural that the fisheries, though important, should not be very profitable. The wet climate does not favour agriculture, and much of the interior is poor moorland, only fit for sheep or deer. In summer the beautiful sea and mountain scenery brings many tourists, who add something to the scanty resources of the islanders. Peat is the chief fuel, and oatmeal and fish the staple diet. Simple habits prevail, and cottage industries are still carried on in the long winter nights. The hand-woven Harris tweeds are made in the south of Lewis, in the north of which is Stornoway, the chief town and fishing centre. Portree in Skye, Tobermory in Mull, and Bowmore in Islay are all tourist centres. Iona, with its relics of early Christianity, and Staffa, with Fingal's Cave, both east of Mull, are much visited in summer.

The North-western Highlands. The map indicates the character of this region. Lying far north, where the summers are short and the winters long, and with little land under 1,000 feet above the sea, the conditions of life must ever be severe, and population scanty. In the west, the mountains come down to the sea, which has drowned the lower valleys, forming fiords. These open to wild and lonely glens, often filled by long, narrow lakes, fed by innumerable mountain torrents, whose waters, browned by a peat soil, leap from boulder to boulder in wild beauty. An occasional sheep-farm or shooting lodge is the only sign of life, for this is the home of the sheep and deer, not of men. Strome Ferry, on Loch Carron, is the only important town. In the north-east is the lower tableland of Caithness, whose red sandstones, resembling those of Orkney, are largely quarried. The softer rock and lower elevation allow of some agriculture, but fishing and sheep farming are still the chief occupations. Bare moors, known as deer forests, are numerous, and the salmon fisheries in the streams bring tourists in summer. Towns are more numerous than in the west, and include Thurso, Wick, Dornoch, Dingwall, Tain, and Beauly.

Two railways reach the west coast, one at Mallaig, from Fort William, at the southern end of Glenmore; one at the Kyle of Lochalsh, beyond Strome Ferry, from Inverness at the northern end of Glenmore. This wonderful natural rift, running from Moray Firth to Loch Linnhe and the Firth of Lorne, divides the highlands into two parts. On either side of Glenmore—the Great Valley, or Glen—tower bare mountains, with here and there a glen opening to east or west between hillsides, which in summer are golden with gorse or purple with heather. In the floor of the glen are Lochs Ness, Oich and Lochy. Across the alluvial flats between them canals have been cut converting Glenmore into the Caledonian Canal. At the north end is Inverness; at the south end of Loch Ness is Fort Augustus, in the centre; and at the south end of Loch Lochy is Fort William, behind which are seen the precipitous flanks of huge Ben Nevis (4,400 ft.), the highest point in the British Isles.

The South-west of the Highlands. This region of sea lochs and mountain glens, part of the South-eastern Highlands, has a beauty all its own. It is inhabited only along the shores of the fiords, where fishing villages are numerous. It is, indeed, most accessible by sea, for few roads and no railways are carried up its steep glens. It is busy and prosperous in the short yachting and shooting season, but the winters are long and lonely. After Fort William, the chief town is Oban, further down Loch Linnhe, a centre of yachting and steamer traffic. This district is connected with the south by the picturesque West Highland Railway. The line from Fort William crosses the desolate, boulder-strewn moor of Rannoch to Loch Lomond, which opens a direct route south to Dumbarton and the Clyde. Another line runs from Oban round Loch Awe to Loch Earn and by the river Teith to Callander. The Lower Clyde, below Dumbarton, is a magnificent fiord, from which smaller fiords open to the north. At its mouth is the hilly island of Bute, with Rothesay, on a magnificent bay, commanding one of the finest views in the world. This is the starting place for the famous Kyles of Bute, a chain of sounds opening to Loch Fyne, at the head of which is Inverary. The western wall of Loch Fyne is formed by the long mountainous peninsula of Cantyre, across which the Crinan Canal gives a short route between Oban and Glasgow. Campbelltown, at its southern extremity, has famous distilleries. East of Cantyre is the island of Arran, with lofty, precipitous peaks, wild glens, and romantic views of mountain and sea. Brodick and Lambash, the largest towns, are little more than villages.

The South-east or Grampian Highlands. These highlands, which lie south of Glenmore, and east of the valleys and lakes followed by the West Highland line, are the most rugged and inaccessible part of the British Isles. They are not, like the South-west Highlands, opened up by winding fiords, and the only natural routes are the Tay valley, opening to the south, the Dee valley, opening to the east, and the Spey valley, opening to the north. Between these is a bleak and lofty region, buried in snow in winter, across which the railways and roads are carried with great difficulty. Much of it consists of grouse moors and deer forests. Sheep farms are scattered among the hill pastures of the lower valleys, and some agriculture is possible where these open to the lowlands. Towns are found only at the valley mouths.



70. GLENMORE AND THE CALEDONIAN CANAL

The southern margin of this great highland area, which descends steeply to the plain and from Perth looks like a mountain range, is called the Grampian Mountains. In reality it is only the edge of a great plateau which it is convenient to call the Grampian Highlands. All the routes from the north converge on Perth on the Tay, and Stirling on the Forth, both on the margin of the plain. From the latter a route goes to Callander, at the mouth of a valley leading to the Trossachs Pass, Loch Katrine, and Loch Lomond, one of the finest tours in the Highlands. Crieff, similarly situated further north, commands similar routes. Perth, on the Tay, at the end of the Sidlaws, commands routes in all directions, and is the key of the Highlands. The main route to the north follows the Tay to Dunkeld, situated like Callander and Crieff. After receiving a branch from the west, by Loch Tay, it traverses the wild ravine of the Garry by the famous pass of Killiecrankie, and crosses the divide to the Spey valley at a height of 1,500 feet. This natural route between the Monadhliath Mountains on the north-west, and the Lochnagar and Cairngorm Mountains on the south-east, is followed as far as Aviemore, through wild and desolate scenery. After Aviemore the main line strikes away from the Spey across the lower eastern end of the Monadliath Mountains to Inverness, while a branch continues by the Spey to the lowlands round the Moray Firth.

Towns in the South-east Highlands. Here towns are numerous, Nairn, Forres, Elgin, Banff, Fraserburgh, and others, those on the coast engaged in fishing and fish-curing. Many small rivers from the eastern slopes of the Highlands cross the north Aberdeen lowland, where Peterhead is the busiest town. Aberdeen, built where the valleys of the Don and Dee converge, has a university, and is a fishing and fish-curing centre, as well as a busy port, shipping grey granite to the south. A line follows the Dee valley to Ballater, near Balmoral, amid the magnificent scenery of the inaccessible Cairngorm and Lochnagar Mountains, the former separating it from the Spey valley. Many valleys, with towns at their mouths, open to the lowlands of Forfar, which form part of the Midland Plain. Montrose and Arbroath on the coast, and Forfar inland, are the largest towns north of the Sidlaws.

The Midland Plain, or Lowlands. At the base of the southern escarpment of the Grampian Highlands extends Strathmore, a broad stretch of old red sandstone, with a deep and fertile soil. It is bounded to the south by a broken line of heights, known under various names, between which the rivers reach the sea. The Tay and Earn reach the Firth of Tay between the Sidlaw Hills of Forfar and the Ochil Hills of Fife. South of the former is the fertile Carse of Gowrie, with Dundee, manufacturing jute and marmalade, as its chief town. Here the Tay estuary is bridged. The Forth, which rises near Loch Lomond, reaches the Firth of Forth, between the Ochils and the Campsie Hills. Stirling, with its towering castle rock, the lava plug which once filled the vent of a long-perished volcano, guards this important gap, and here the river forms its famous links or windings. The Clyde, from the Southern Uplands, with fine falls where it enters the lowlands, reaches the western sea between the Campsies and the Renfrew Heights.

The Scottish Coalfields. South of these heights, which divide the Midland Plain into two parts, are the Scottish coalfields [**69**]. The Ayrshire field, which lies west of the Renfrew Heights, and is consequently isolated except by sea, ships much of its output from Troon and other ports to the manufacturing towns of the opposite coast of Ireland. Kilmarnock, manufacturing woollens, is the chief town of the Ayrshire field. The central, or Forth and Clyde field, extends up the Clyde as far south as Lanark, and as far east as the Forth estuary. Glasgow, built like many other prosperous cities, at the lowest point where a navigable river can be bridged, is the centre of one of the busiest industrial districts in the world. It has immense shipbuilding and engineering works, chemical and other manufactures, and an enormous transatlantic trade. Both banks of the Clyde as far as Greenock are lined with busy towns similarly engaged—Port Glasgow, Greenock, Dumbarton, and others. Of the inland towns, Coatbridge and Airdrie have mining and iron industries, and Paisley manufactures into thread the cotton brought across the Atlantic to Glasgow. The eastern part of the coalfield, with fewer facilities for obtaining raw material by sea, is less busy. Stirling makes tartans, carpets, and other woollens, and Falkirk has collieries, ironworks, and chemical manufactures. The smaller coalfields of Fife and Midlothian are on opposite sides of the Forth estuary. On the former, Burntisland and Kirkcaldy ship coal, Dunfermline manufactures linens, and Kirkcaldy linoleum. The coast is ringed with fishing villages from Inverkeithing to St. Andrews, an ancient ecclesiastical city and university. On the Midlothian coalfield the chief town is Edinburgh, the capital. It is built where the Pentland Hills approach the sea, round a castle-crowned volcanic crag like that of Stirling. There is no road to the north till Edinburgh is reached, and it also guards the routes south into England and west to the Clyde. It has a famous university and medical school. Among its industries paper-making, printing, and brewing are important. Its port is Leith. Above Edinburgh is the great Forth Bridge across the estuary. In the neighbourhood of Edinburgh are collieries and oil shale works, and many paper-mills, worked by the streams coming down from the Pentlands. Fishing villages dot the southern shore of the estuary. Dunbar, at the base of the Lammermuirs, controls the route from England to Scotland round their eastern base.

The Southern Uplands. A line drawn from Dunbar to Girvan, on the Ayrshire coast, marks the northern limit of rocks older than those of the plain, but younger than those of the northern highlands. These form the Southern Uplands. The scenery is less picturesque than that of the highlands. Instead of bare, rocky peaks and precipices, the hills have rounded forms, and soil enough for coarse pastures, bare rock being seldom seen. The four river valleys, of the Clyde, Nith, Annan, and Tweed, must be noticed. That of the Clyde has already been described. The Nith valley, at the mouth of which is Dumfries, with woollen, iron, and leather manufactures, forms one of the main routes between Carlisle and Glasgow. West of the Nith the hills are wilder and the valleys more fertile. Kircudbrightshire is famous for its heather honey. Salmon fisheries are important in the Solway Firth. Sheep and cattle are kept throughout this region, the Galloway cattle being a famous dairy breed. East of the Nith is the Annan, giving a route to the Clyde valley. The railway crosses the divide at Beattock, in a sheep-farming district, with a great annual sale of Cheviot rams. The height at Beattock is nearly 1,000 ft., and the surrounding hills rise to 2,500 ft. East of the Annan route passes lead to Selkirk and the Tweed valley, which widens in the east to a considerable lowland. Its tributaries—Gala, Yarrow, Ettrick, Teviot, and others—drain a high, bleak region occupied by scattered sheep farms. The wool is manufactured in small towns in the valleys below—Peebles, Innerleithen, Galashiels, Selkirk, Hawick, and others—all of which are important market towns. Ruined abbeys, of which Melrose on the Tweed is the most famous, show how long this district has been prosperous, and how disastrous were the interminable English wars. Many old keeps and border castles tell the same tale. On the lower Tweed are Kelso, the centre of a rich agricultural district, and Berwick, on the English border. The route from Carlisle to Edinburgh crosses the Southern Uplands by the Liddel, Tweed, Gala, and Esk valleys. That from Berwick skirts their eastern base.

page 980

THE MUNICIPAL TREASURER

The Duties and Salaries of the Finance Department of Municipal Authorities: Training, Qualifications, and Examinations

By ERNEST A. CARR

THE financial staff of a local authority is less liberally remunerated, on the whole, than that of the town-clerk—the branch we last considered. The explanation, doubtless, is that many subordinate positions in the accounts department are ordinary clerical appointments, whilst the town-clerk's staff requires special training, only an expert being able to perform satisfactorily the duties of a committee or election clerk. Leading financial positions, however, as we shall see, need quite distinctive knowledge and abilities, and are correspondingly well paid.

The Head of the Finance Staff. There is a good deal of diversity of practice as to the title and duties of the head of the finance staff. To quote a distinguished authority, who is himself holding such a post in a prominent county borough, "The chief financial officer of a corporation is styled either Comptroller, Treasurer, or Accountant, the duties of each being of a somewhat similar nature. The position of treasurer is, however, the statutory one, and the majority of corporations are now appointing their leading financial officer in that capacity." In many instances the staff includes both treasurer and accountant, the first holding the senior rank. In some municipalities the two offices are united in a single official; whilst others, again, place the control of their finance department under the borough accountant, and employ a member of a banking firm or the manager of a bank as their nominal treasurer.

Whatever his title, the chief of the financial and accounts branch holds a very responsible office. He is in general charge of the revenues and disbursements of his authority, such large sums passing through his hands that security to the extent of £5,000 or £10,000 is usually required of him. As expert adviser to the council on the financial side of their many operations he has an anxious duty to perform. Not only is he consulted as to the conduct of such matters as raising and extinguishing loans, issuing stock, and fixing terms and rates of interest; the soundness or otherwise of important "municipal trading" schemes, and the proportion of expense which these undertakings should bear, are among the grave questions on which his opinion is of weight. He must further be familiar with the complex system on which municipal accounts, as a whole, are kept, and the bookkeeping methods best adapted to the special needs of trading and other departments. These qualifications can only be acquired by a wide experience of municipal finance in all its branches.

As already pointed out, no absolute distinction can be drawn between the treasurer and the accountant; but where both offices are separately held under the same local authority, the treasurer's concern is mainly with finance and securities, the accountant's with bookkeeping and office checks on expenditure. In these circumstances the former official holds the more distinctly professional appointment; otherwise, the requirements for either position are practically identical, and we may conveniently defer the discussion of their qualifications in order to deal with both together.

The Influence of Municipal Trading. We have seen, in considering electrical and gas engineering and other appointments, that the last decade or so has witnessed an astounding development in the commercial or "trading" activities of local authorities. During that period the revenues derived from public baths and wash-houses, tramways, and the supply of municipal electric light, gas, and water, have increased by leaps and bounds; and there appears to be every prospect of a continued increase for many years to come. The bearing of this development on the finance and accounts staff is too direct to be overlooked. In the words of the expert already cited, "The very large commercial undertakings which are now being carried on by municipalities throughout the country have, during the last few years, materially increased the responsibilities of the finance department, and the importance of its work becomes more and more manifest from year to year." The growth of a department involves a greater number of highly paid offices in it, and thus affords increased scope for able members of the staff.

Treasurers' Salaries. This fact is instanced by the case of the London County Council's chief financial officer, the Comptroller. So greatly has the work of his office increased during the past six years that his salary has advanced in that time from £1,150 to £2,000 a year. The latter is an exceptionally high figure, of course, though it is surpassed in at least one instance. The Chamberlain to the City Corporation, who acts as its treasurer and banker, receives £2,500 a year, rising to £3,000. It should be added that he is an exceptionally able financier, having gained invaluable experience by many years' partnership in a great banking firm. Under less distinguished authorities the income of county and borough treasurers varies considerably, ranging from £500 to £1,600 a year, according to the size of the local body they serve and the importance of the works it controls. Deputy treasurerships are remunerated at about one-half or three-fifths of the salaries attaching to the principal posts. The treasurer to the Manchester

Corporation is paid £1,000 a year, and his deputy £500. On the other hand, the treasurership of a minor county was recently advertised at as small a stipend as £250 yearly, which is probably the low-water mark for an office of that class.

Municipal Accountancy. Where the accountant's functions are distinct from those of the treasurer, they may be summarised as comprising the direct charge of the accounts staff, and a general supervision over the bookkeeping in every other department, so as to safeguard the local authority from losses through carelessness or fraud and to facilitate the periodical inspection of the accounts by the Local Government Board auditor. It is the accountant's duty also to control the collection of moneys, and to frame from the various departmental accounts those elaborate financial statements which are necessary to disclose the position of the county or borough as a whole. The work thus briefly indicated is more complex than anyone who has not explored the mazes of Local Government accounts would be disposed to believe. Its proper performance needs something like a gift for figures, as well as a close familiarity with municipal accounting methods, and inexhaustible patience and alertness.

Owing chiefly to the difference of duties already pointed out, accountancy posts, as a class, are less liberally repaid than treasurerships. They range in value from £250 to £1,000 a year, the latter figure being rarely exceeded. Further details are afforded by the following list of actual appointments of both chief and assistant rank :

Accountants :

Northumberland, £800.
City (accountant auditor), £625.
Nottingham County, £350.
Manchester, £300 and £500.
Holborn, £350.
Wandsworth, £330.
Leyton, £300, rising by £25 annually to £450.
Acton, £250, rising by £20 annually to £350.
Longton, £250.

Assistants and Deputies :

York, N. Riding, £250, rising by £10 annually to £450.
London Water Board, £255, rising by £15 annually to £300.
Manchester, £215.
Holborn and Hull, £180 to about £250 each.
Willesden (accountant's clerk), £150 to £200.

Training and Qualifications. Candidates for county or borough treasurerships are generally required to have qualified as professional accountants, and to be thoroughly versed in municipal accounts and finance, as well as accustomed to control a staff of clerks. For the municipal accountant the same conditions apply, except that in his case a professional diploma is not always insisted upon, vacancies being filled by the promotion of experienced and deserving assistants or accountants' clerks at least as often as they are advertised or reserved for "admitted" men.

The shortest and surest route to a principal position of either grade is to enter as an articled clerk the office of a borough treasurer or accountant who is a Fellow either of the Institute of Chartered Accountants or of the Society of Accountants and Auditors. These are the two general accountancy bodies whose diplomas carry most weight within the municipal world as well as without. Their examinations will be found fully discussed in the CLERKSHIP AND ACCOUNTANCY course, and need not occupy us here.

In this way the student, whilst gaining valuable experience in the practical side of municipal accounting, can prepare for the examinations admitting to the Associateship, and ultimately to the Fellowship, of one of the two institutions named.

On the expiry of his articles he may look with some confidence for an assistantship, and later for a principal appointment. Such a direct road to promotion should on no account be neglected by the fortunate youth to whom a moderate premium and a term of service without a salary present no insuperable obstacle.

On the other hand, the same advancement is within reach of a member of the clerical rank and file who has neither means nor influence to smooth his path, and this fact constitutes the great counter-advantage of the finance branch as compared with more highly paid departments. The post of borough engineer, medical officer, or surveyor, for instance, is almost out of reach of those who are not specially and expensively trained from the start ; but there is no reason why any aspirant for a leading financial post should not—with good abilities, a fair general education, and an aptitude for figures—attain his ambition whilst supporting himself throughout.

One Way of Success. It will be worth while to consider shortly the steps by which a clever lad may pursue from small beginnings such a career as has been indicated. An early start is perhaps the foremost essential for success under these conditions.

Years of practical experience are needed to master the complexities of the many branches of municipal accounting; and local authorities, finding that their best finance officials are those who have been trained to the work from their youth, are reluctant, as a rule, to appoint untrained clerks to these duties after the age of 25 at the latest.

The ambitious youngster will probably gain his footing on the first rung of the ladder of promotion between the ages of 15 and 18 by a position as office youth or junior clerk on the borough treasurer's or accountant's staff. Here he must take every opportunity that arises to master the details of account-keeping, supplementing this practical training by evening classes in bookkeeping, banking, and commercial subjects. In this way he will be qualified for the post of office clerk or junior bookkeeper when a suitable vacancy arises; and after a few years' further experience in that capacity, he should be ripe for promotion—either in the same office or by transfer—to the grade of chief bookkeeper or accounts clerk.

Meantime, it will be advisable for the budding accountant to direct his studies towards obtaining a recognised qualification. We have seen that this is not an indispensable step, but, on the other hand, it offers no colossal difficulties, and, in view of the great value of a professional accountancy diploma when competing for a leading appointment, even the hardest-worked accounts clerk should not neglect it for any but the gravest reasons.

Of the two accountancy associations already mentioned, the Institute of Chartered Accountants admits to its examinations only those students who have served at least three years' articles to a member. For such a self-dependent youth as we have in view, this is an absolutely prohibitive condition, unless his office chief should be himself a chartered accountant, and would grant him his articles on exceptionally favourable terms.

The Society of Accountants and Auditors, however, accepts candidates, other than articled clerks, who have served a specified term of years (six for the intermediate, and nine for the final examination) as clerk to a municipal or other public accountant. The official who is resolutely seeking a professional status may, therefore, find it expedient to take this Society's final examination as soon as possible after reaching the minimum age of 25. He must then wait for promotion to a principal clerkship before he is eligible for the Associateship or Fellowship (A.S.A.A. or F.S.A.A.).

There cannot be two opinions as to the value of this qualification for municipal work. The Secretary of the Society of Accountants and Auditors states that "the post of borough treasurer or accountant to the large majority of the boroughs throughout the country is held by members of this society, the diploma of which carries a great deal of weight in any competition for such an appointment." A reference to the lists of municipal officials amply confirms this claim.

The I.I.M.T.A. There exists, however, for the benefit of municipal officers alone, a somewhat similar society, whose examinations are of especial value, since they are directed to the particular branches of accountancy with which such officials are concerned. This is the Incorporated Institute of Municipal Treasurers and Accountants.

Membership of this body is widely recognised as a proof of efficiency, many local authorities, when advertising a vacancy for a treasurer or accountant, accepting that qualification equally with the F.C.A. or F.S.A.A. diploma. The young student of local government accountancy will, therefore, probably be attracted to an I.I.M.T.A. certificate in preference to those of the other two bodies named. The examination subjects, fees, and other particulars, are set out in the accompanyng schedule. Examinations, both preliminary and final, are held yearly. The centres are determined after all applications are received, but always include London and one Northern town, at least. The scope of these tests is thus defined by the regulations of the Institute:

"The preliminary examination is designed to ascertain that candidates have a practical elementary acquaintance with the business of the finance department of a municipal corporation or kindred authority.

"The final examination is of an exhaustive character, and is designed to test the knowledge of candidates in the whole range of municipal finances and the law relating thereto."

Having attained this, or an equivalent certificate, the former office youth should find himself in the position of chief finance or audit clerk, or assistant accountant, and is fully qualified for an accountancy proper. If he is fortunate, as well as able, he need not have long to wait.

Age Limits. Many chief accountancy positions are held by young men of less than 30. One such post in a busy London borough, at a commencing salary of £350 a year, was lately won by a public accountant of 31; and that at Acton (shown in our list) was restricted to candidates between 28 and 35 years of age. More usually, however, the upper limit is extended to 40 or beyond.

The post of professional auditor, it may be mentioned in passing, is generally held by an accountancy firm in private practice, who provide their own staff of clerks for the audit, and are paid by fees varying from a hundred guineas to nearly ten times that sum.

Rate Collector. For the office of rate collector, no particular qualification is prescribed. The only essentials are integrity, exact bookkeeping, and a general knowledge of the way in which rates are made and recovered. Applicants are not restricted to any one department, and, indeed, are sometimes appointed without previous municipal experience of any kind. The best training, however, is afforded by a clerkship on the rating staff, and from this class the ranks of the collectors are largely recruited. These officers must reside within the district for which they are appointed, and must provide an office and safe. They are usually required to undergo a medical examination before appointment, and to give security for their honesty. Their duties are monotonous, and occasionally distasteful, but considering that no special knowledge or training is needed for the post, they are well paid. The method of remuneration varies; sometimes it is a fixed, and at others a progressive stipend, whilst the income of some collectors varies with the number of assessments on which the rates are recovered. For the smaller districts, £150 to £200 is the usual salary, and for the larger areas £250 to £350, and sometimes £400. The City Corporation pays its chief collector £500 a year, and this is sometimes exceeded, a suburban official having lately refused an offer of precisely that fixed salary in lieu of the percentage he at present receives on all sums collected. But although the rate collector is well remunerated, he has rarely any prospects of further advancement. "Once a collector, always a collector," is an axiom of the service.

Continued

MUNICIPAL TREASURERS AND ACCOUNTANTS

Examining Body, Time, Grade, Place of Examination.	SUBJECTS OF EXAMINATION.	Fees and Age Limits.
PRELIMINARY. INSTITUTE OF MUNICIPAL TREASURERS AND ACCOUNTANTS (INCORPORATED).	1. **Accountancy:** Bookkeeping and accounts of local authorities. Local authority finance: auditing (rate collection, tolls, etc.). Arithmetic and algebra. 2. **Law:** General principles affecting municipal treasurers and accountants, including statute and common law, real and personal property: mortgages, deeds, agreements, etc., contracts, local rates, duties of overseers, borrowing and rating under certain statutes **Note.**—Candidates must have served three years in finance department of municipal or kindred authority. Successful candidates become student members of the Institute.	£1 1s. See note.
FINAL. Each June at two (or more) centres—*viz.*, London and in North of England.	1. **Accountancy:** Bookkeeping and accounts of local authorities, including material and stores, loans, sinking funds, depreciation and reserve funds, etc., trading undertakings, education, abstracts and balance-sheets. 2. **Local Authority Finance:** Estimates for rates, assessment and rating, capital expenditure, revenue and income, and expenditure, borrowing powers, income tax. 3. **Auditing:** Audit and check of accounts in finance and other departments. 4. **Law:** Municipal Corporations Act, Public Health Acts, Local Government Acts, etc. Duties of overseers, making and enforcing rates, audit of accounts (*a*) audited by Local Government Board auditor; (*b*) not so audited; mortgages, deeds, agreements, etc. **Note.**—Candidates must be Associates of the Institute, or of the I.C.A. or S.A.A., or Student Members of two years' standing, or, if they have served five years in finance department, of one year's standing.	£2 2s. See note.

MEN CLERKSHIPS, LONDON COUNTY COUNCIL

Examining Body, Time and Place of Examination.	SUBJECTS OF EXAMINATION. PART I. Candidates holding certain matriculation or other certificates are exempt from this test. PART II. Shorthand also may be taken as a non-competitive, but useful subject [see Letterpress].	Fees and Age Limits.
THE LONDON COUNTY COUNCIL, Spring Gardens, S.W. When requisite, usually two or three times yearly: Part I. at several London centres, Part II. at one such centre.	**Part I. Preliminary** (Two days). 1. Handwriting } marked from papers 3, 5, and 6. 2. Orthography } 3. English Composition (Essay writing). 4. Arithmetic: Fractions, decimals, cube root and mensuration. 5. English History, including a special period. 6. Geography, including the United Kingdom and another special section. 7. Euclid, Books I.-IV., and VI., or equivalent geometry. 8. Algebra, to binomial theorem. 9. Plane Trigonometry (excluding analytical): solution of triangles. **Note.** All subjects are compulsory. Special importance is attached to 3 and 4.	10s. 18 to 23 years.
	Part II. Competitive (Six days). 1. General Knowledge (*compulsory*). *Any four of the following may also be taken* 2. English Language and Literature: including essay and special books. 3. Pure Mathematics: (i.) higher algebra, (ii.) higher trigonometry and geometry, differential and integral calculus. 4. Applied Mathematics: including analytical statics, particle dynamics, and hydrostatics. 5. and 6. Modern Languages (two): Translation from and into, accidence, and pronunciation. 7. Latin: Translation from and into, accidence and syntax. 8. English History, including a special period. 9. Economics: theory and history, policy of tariffs, etc. 10. Outlines of Local Government: functions of authorities, rates and taxes. 11. Elements of English Law: constitutional law, contracts, evidence, etc. 12. Experimental Mechanics: construction and use of apparatus, proofs of mechanical principles, etc. 13. Experimental Physics: laws and phenomena, laboratory methods for simple physical measurements. 14. Chemistry, practical and theoretical, including metallic chlorides, nitrates and sulphates, compounds of iron, sodium and potassium, etc. 15. Bookkeeping and Accountancy, including nature and use of office books, principles of double entry, etc. **Note.** In subjects 1, 2, 5, 6, 12–14, the examination is both written and oral. Practical Knowledge of experimental methods is essential in 13 and 14.	10s. 18 to 23 years.

Full particulars, with a detailed syllabus of subjects, can be obtained from the Clerk of the London County Council, Spring Gardens, S.W. The papers set at past contests are supplied by Messrs. P. S. King and Son, 2, Great Smith Street, Westminster, S.W., at 5½d. per set, post free. Approaching examinations are advertised in the leading London newspapers

THE SEDIMENTARY ROCKS

How Sedimentary Rocks were Produced. Sandy and Clayey Rocks. Limestones. Coal. Volcanic Rocks. Metamorphism. Schists

Group 14
GEOLOGY
5

Continued from page 1009

By W. E. GARRETT FISHER

have already seen quite clearly that the igneous rocks are the oldest constituents of the earth's crust. Since the earth once existed in the form of a nebula, or fiery cloud of warring atoms, and cooled by successive stages into the planet which we now inhabit, it is perfectly evident that there was a time when its surface consisted solely of igneous rocks—granites and basalts, and their allied families. But at present the most casual observation tells us that this is no longer the case.

Sedimentary Rocks. The surface of the earth is mainly covered with what we call *soil*, the product of disintegration of hard rocks by atmospheric and other agencies. This layer supports all life on the earth, because it brings forth vegetation, and so feeds animals, and, directly or indirectly, mankind. Underneath this we find a *subsoil* of very varying formation, if we examine it by driving a shaft or a borehole, or by studying the sections of the crust which are made by natural cliffs, as on the sea-coast, or by artificial cuttings for a railway line or a quarry. Sometimes the soil lies on the top of what we can recognise as an igneous rock; some of the most productive of Italian vineyards, for instance, are separated by only a thin layer of rich soil from the lava of a volcano. But more frequently the subsoil proves to be different from any of the igneous rocks that we have studied. It is non-crystalline, is arranged in definite layers or *strata*, and contains fossils, or relics of vanished forms of life. By all three characteristics, or by the two first, which are often present without the third, we then decide that this subsoil is not an igneous but a *sedimentary* rock. In other words, it must be a product of later growth than the igneous rocks; for as the whole of the crust was once igneous, the sedimentary rocks must have been derived from these, whence they are sometimes called *derivative* or *secondary* rocks. In later chapters we shall have to study the processes by which the sedimentary rocks have been produced. First, however, we must make acquaintance with their various characteristics and the families into which they may be divided.

How Sedimentary Rocks were Produced. The classification of the sedimentary rocks is much simpler than that of the igneous rocks. They are far less varied and complicated in structure than those from which they are derived, partly because the natural agencies which have broken down the igneous rocks into these secondary products are less powerful and consequently less sweeping in operation than the agencies of heat, chemical action, and pressure which have produced the igneous rocks. The latter were compounded in the great laboratory of Nature, in the molten interior of the planet; the former came into existence on the earth's surface under the milder influence of rain, sea and rivers, frost and ice, wind and weather. It is quite natural that their forms should be less complex and their origin easier to comprehend. We shall see later how they were produced. It is enough to say here that they have all been formed of fragments broken from igneous rocks, and deposited in layers. This was generally due to the action of water, in which they were mechanically *suspended*—like the mud in a brook that runs dark and turbid after heavy rain—or chemically *dissolved*, like the salt in the sea. They are, in fact, the *detritus* of the earlier world, the broken-down relics of the primitive igneous rocks. A possible way of classifying them would be according to the nature of the agency which broke down the older rocks and rearranged them, as follows:

(*a*) *Æolian* rocks, produced by the action of wind, like the vast beds of loess which form some of the most fertile tracts of China.

(*b*) *Aqueous* rocks, formed by the agency of water. These form much the largest group, and may be subdivided, according to whether the fragments have been deposited from a condition of mechanical suspension in the water—sandstone and shale—or have been crystallised from a solution—rock salt and crystalline limestone.

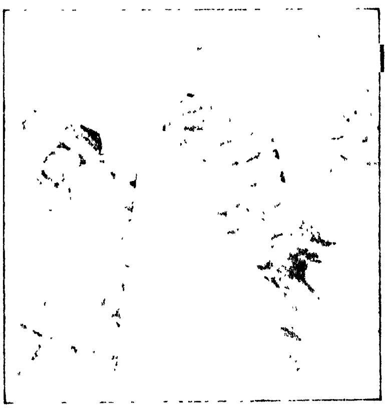
(*c*) *Organic* rocks, formed by the action of life, like coral, chalk, and many limestones.

(*d*) *Volcanic* rocks, or *Tuffs*, which result from the breaking up of lavas and their ejection in fragments by volcanic eruptions.

Classification of Sedimentary Rocks. This classification deserves notice, as it gives a preliminary idea of the methods by which the sedimentary rocks were formed. But it is not a very good one, as the examples named will show. Are we to classify chalk, for instance, as an aqueous or an organic rock? It was all laid down by the water of the sea, in which its constituents were once floating. But it is also mainly composed of the remains of innumerable tiny creatures, which formed the calcium carbonate of the sea water into shells and skeletons. Probably the most convenient classification is that which depends on the chemical composition of the rocks. We find by investigation that the sedimentary rocks are far less complicated in this respect than their igneous ancestors. The great majority of them are composed mainly of one of four minerals—*sand, clay, lime*, or *carbon*. According to the prevalence of one or other of these substances, we may divide the sedimentary rocks into four great families: the *arenaceous* or sandy, *argillaceous* or clayey, *calcareous* or limy, and *carbonaceous* or coaly rocks. A fifth class is necessary, indeed, to contain the few sedimentary rocks which refuse to fall into one or other of these families. But that only shows that Nature declines, here as elsewhere, to work according to the strict logical distinctions of the theorist.

A short account of the chief sedimentary rocks with which the geologist has to familiarise himself may now be given. It should be supplemented by reading one of the fuller text-books, and by examination of actual specimens in a museum and in the field.

Arenaceous, or Sandy, Rocks. These are composed mainly of *sand*, which is simply an aggregate of tiny fragments of quartz—pure silica—more or less rounded, and not bound together by any cement. We are familiar with it on the sea-shore, on the margins of lakes and rivers, and by hearsay, as the soil of vast deserts in drier parts of the world. This sand is the débris of quartz rocks, granite, etc., caused by the wear and tear of ages. Sometimes the process has not been carried so far, and instead of sand we have *gravel* or *shingle*, such as collects at the bend of a river, where the current runs less swiftly and so is unable to drag it further along. It is impossible to assign any limit of size beyond which these débris cease to be débris and have to be considered as part of the original rock; but one may say roughly that sand consists of particles ranging from the size of a small pea down to impalpable powder, gravel of particles ranging from a pea to a walnut in size, whilst shingle may range from that up to blocks a foot or more in diameter. Further, a distinction has to be drawn, in practice, between *rounded* sand and pebbles such as are found on a sea-beach, where the waves have been grinding the particles against one another till all corners are worn off, and *angular* fragments of more recent origin found in a quiet spot.



29. RIPPLE-MARKED SANDSTONE
From Wealdon

The various forms of quartz detritus known as sand, gravel, shingle, and pebbles form the raw material of the chief sandy rocks. They are again united into a solid rock in two ways. The mere pressure of the superincumbent strata is often sufficient to consolidate fine particles of sand into a coherent mass—just as powdered graphite is squeezed in a hydraulic press until it forms the solid lead for our pencils. In other cases the separate particles are held together by a hard cement, or *matrix*, which may be hardened sand or clay, or chemical cement precipitated from solution in water. The numerous varieties of sandy rocks owe their countless differences to the union of different kinds of particles by different kinds of cement.

Sandstone. *Sandstone* [29] is a rock formed of consolidated sand, held together by its own coherence or by a cement, which may be of iron oxide (which gives its colour to most of the red sandstones), of clay, of carbonate of lime, of silica, or other material. Thus, we have ferruginous, argillaceous, carbonaceous, siliceous, and yet other sandstones. If the grains of sand are somewhat coarse and angular, so that the stone, when broken, feels very rough to the touch, it is known as *Gritstone*.

Greywacke is the name given to a particularly compact and hard sandstone, of a prevalent grey colour, which is the hardened muddy sand of very ancient sea-floors. *Flagstone*, used for pavements, is a sandstone which splits into thin flags along the planes of bedding or stratification. *Freestone* is a sandstone which can be cut with equal ease in any direction, and shows no such tendency to split up.

Conglomerate. This, popularly known as *pudding stone* [30], is a rock in which the sand is replaced by gravel or shingle, held together by a cement which may consist of hardened sand or clay, or of the materials mentioned in the last paragraph. The rounded pebbles, which give character to the conglomerate, may be of quartz granite, limestone, or many other rocks.

Breccia. *Breccia* [31] is a rock in which the pebbles, instead of being rounded, as in conglomerate, are angular. The real distinction between the two is that conglomerate points to the action of water, which always tends to round pebbles exposed to its action, and breccia to atmospheric denudation (such as forms cliff screes and glacial moraines), which leaves the fragments much as they were when broken off by frost or other weathering influences.

Argillaceous, or Clayey, Rocks. These are composed of fine argillaceous sediment, derived from the waste of rocks, especially of granites and other rocks which contain the felspars as ingredients. *Clay* itself is a hydrated silicate of alumina, which is a product of the decomposition of felspar. It occurs in many varieties with differing compositions, of which *kaolin* or *china clay*, *pipe-clay* and *fire-clay* are well-known examples. *Brick-clay* is a name industrially given to the coarser clays. *Loam* is a mixture of clay and sand, which provides an excellent soil for many kinds of vegetation.

Loess, again, is a clay which has been accumulated probably by wind-drifts to the depth of hundreds of feet in the great river valleys of China, where it plays an important part in agriculture. *Boulder-clay*, or *till*, is a stiff, sandy clay, full of boulders of all sizes, which is found only where ancient glaciers once ground to powder all but the hardest fragments of rock, and in which these surviving fragments are still found embedded. All these, it will be remembered, are rocks in the geological, though not in the popular, sense of the word.

30. CONGLOMERATE, OR PUDDING STONE
From Woolwich and Reading Beds

Under pressure of overlying strata, ancient clays have hardened into compact rocks. *Mud-stone* is the intermediate stage between clay and rock, in the popular sense. It has no tendency to split into plates, and is easily rubbed down into mud with the aid of water. *Shale* is a general term given to any clayey rock which splits easily into thin layers; there are countless varieties, according to what other material—as iron pyrites, sand, limestone, or carbonaceous matter—happens to be present with the clay. *Oil-shales* are used in the manufacture of paraffin. *Slate* is a hard, clayey rock which splits into thin, regular plates along its cleavage planes, which are not necessarily the same as the bedding planes that represent the original surfaces of stratification. It is much employed in buildings, owing to this convenient property.

Calcareous Rocks, or Limestones. These consist mainly of calcium carbonate. The purest example is *chalk* [32], a soft rock which often contains more than 90 per cent. of calcium carbonate. It is composed of the shells and skeletons of minute organisms which once lived in primeval seas, from whose waters they extracted the calcium carbonate, which they built up into wonderfully beautiful, though microscopic, structures, which fell down to the sea-bed when the organisms died and rotted, ultimately forming deposits of hundreds or thousands of feet in thickness during the lapse of long geological ages. By far the larger number of *limestones* are similarly of organic origin. They vary in hardness and in chemical composition so widely that it is impossible to give any account of their varieties. It must be noted that in many cases limestone, though a true sedimentary rock, presents a crystalline structure, since it is soluble in water—especially if carbonic acid be present—and may crystallise out if it is again deposited from this solution. *Marble*, as we shall see later, is a limestone which has been crystallised by heat, and belongs properly to the section of metamorphic rocks.

31. BRECCIA

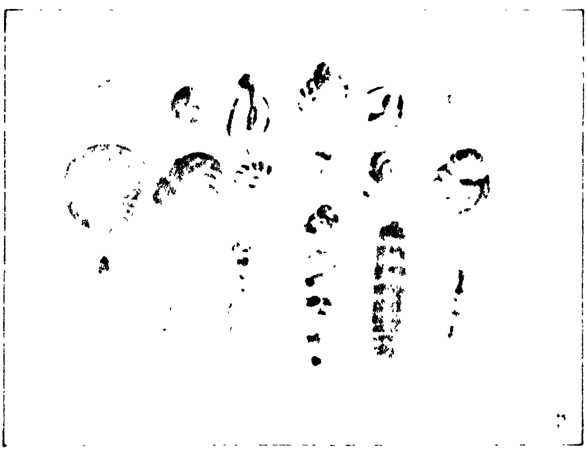
The *magnesian limestones*, or *dolomites*, are an important class of calcareous rocks, which consists of a mixture of calcium carbonate with magnesium carbonate. All limestones have the important property that when they are heated, or "burnt," the carbon dioxide (CO_2) is driven off as gas, and quicklime (CaO) is left behind [see CHEMISTRY]. They are easily recognised by the fact that they effervesce when acid is dropped on them, carbon dioxide being again given off and forming bubbles in the acid.

Among calcareous rocks we must note those containing phosphate of lime, which arise chiefly from organic sources, and are valuable for their use as fertilisers. These include *guano*, *bone-breccia*, *phosphatic chalk*, and the *coprolites*, or fossil excrement, which often occur in whole beds. Geologically these are of little importance, save as bearing witness to the earlier forms of life.

Carbonaceous Rocks. Carbonaceous rocks have almost all been derived from the decay of vegetable matter. They play an important part in human life as the chief sources of heat and power. Indeed, there is no rock, with the possible exception of the flint which first taught man to make himself tools, that has had so much influence on the course of human civilisation. *Peat* is the most recent form of carbonaceous rock, and can easily be recognised as recently decayed vegetation, found chiefly in boggy places. *Lignite*, or *brown coal*, is a more advanced stage in the mineralisation of vegetable matter, and occurs in strata more recent than those of the coal measures. *Coal* is a true rock, which contains 75 to 90 per cent. of carbon, along with oxygen, hydrogen, and nitrogen — the chief organism-building elements—and with impurities which are left as ash when the coal is burnt. For a special account of the numerous varieties of coal, with their special uses, the reader must consult the course on MINING. We need only mention *anthracite*, which is the most completely mineralised form of coal, and contains over 90 per cent. of carbon. The volatile constituents have been expelled from it, probably by the near approach of intrusive volcanic rocks, so that in a sense it is a metamorphic rock. The valuable Welsh *steam-coal* is a form of anthracite. *Petroleum*, which may be termed a liquid rock—as mercury is a liquid metal—at ordinary temperatures, is also a product of decayed vegetation, possibly due to the destructive distillation of coal under great pressure in the lower strata of the crust. *Asphalt* is probably of similar origin. *Graphite* occurs in large masses in places as far apart as Cumberland and Ceylon, and must be named under this head. Its origin is not clear, but it is known to be practically pure carbon, and may thus rank as the last step in the alteration of vegetable matter.

Other Sedimentary Rocks. There are a small number of sedimentary rocks which have found no space inside this classification, but must be mentioned in the course of such a review.

Siliceous Sedimentary Rocks are of organic origin, and consist of the shells and skeletons of marine organisms which chose to build their frail houses of silica rather than of limestone. The most important of these is *flint* [33], which is practically pure silica, partly amorphous and partly crystalline. It is found in nodules, usually dispersed through the chalk strata. It is believed that these nodules or lumps were formed by the chemical deposition of the silica of the sea-water around the nuclei afforded by the siliceous skeletons of dead sponges or diatoms. The great importance of flint from a human point of view lies in the fact that, though intensely hard, it can easily be chipped into shapes with sharp edges, and so lends itself more readily than any other material to the manufacture of primitive cutting instruments [34 and 35]. It is not too much to say that the whole fabric of our civilisation is based on flint.



32. PHOTOMICROGRAPH OF CHALK
(Magnified 100 diameters)

Crystalline Sedimentary Rocks. These, though not very common, do occur. We have seen that there are two ways in which a mineral may crystallise—either by cooling from a state of fusion, or by precipitation from a solution in water or other liquid. *Diamonds* are undoubtedly formed in the latter way, by the crystallisation of carbon which has been dissolved under great pressure in molten iron. *Rock salt*, which is found in beds hundreds of feet thick, and often assumes a crystalline structure, is clearly the relic of ancient seas or salt lakes which have gradually dried up. *Limestone* is often found in a crystalline form, due to the fact that it has dissolved in water containing carbonic acid gas, and has again been deposited in crystalline form. *Travertine*, or calc-sinter, is thus deposited by calcareous springs, while the *stalactites* and *stalagmites* of limestone caverns are of similar origin.

Volcanic Fragmental Rocks. *Volcanic fragmental rocks*, or *tuffs*, though not in the strict sense of the word sedimentary rocks, are usually included in this family. They consist of the materials ejected from volcanoes otherwise than in the form of lava. They vary in size from *volcanic bombs*, often several feet in diameter, to the impalpable *volcanic dust*, which floats in the air long after an eruption and slowly settles down on the earth, where it becomes stratified just as if it had been deposited by water. *Volcanic tuffs* are rocks formed of this kind of detritus, fine or coarse, which vary, according to the nature of their materials, from a coarse *volcanic conglomerate* to a fine-grained rock. They are found, of course, only in the neighbourhood of ancient volcanoes, and usually shade off into true sedimentary formations.

Metamorphic Rocks. There is a third class of rocks which are neither igneous nor sedimentary—that is, these rocks are no longer in the original state in which they solidified from the molten core of the earth's crust, nor yet have they been broken down and arranged in strata by the action of water or atmospheric influences. They have, however, undoubtedly been altered from the condition in which they were first produced, and accordingly they are described as *metamorphic* or *altered rocks*.

Their present state bears witness to the action of many and various agencies of change. Some of them are igneous rocks which have assumed a false stratification in consequence (probably) of the pressure of superincumbent layers or of pressure exerted from the side by the great deformations due to the shrinkage of the earth's crust and its consequent wrinkling into mountain ranges. Others are sedimentary rocks which have assumed a false crystalline character through the action of heat, usually due to their coming in contact with intrusive floods

33. NODULE OF FLINT
Showing imbedded fossil

of molten lava welling up from beneath the surface — *contact metamorphism*. *Marble*, for instance, is a metamorphic rock which is now crystalline. It was once sedimentary limestone, which has been melted under great pressure and has crystallised in cooling. If we heat limestone under the normal conditions which obtain at the earth's surface, it does not melt, but the carbon dioxide passes off as gas, and lime is left behind, as occurs in every lime-kiln. But if the limestone be enclosed in a steel chamber so strong that the pressure of the escaping gas cannot burst it, it is possible to melt it, and to produce a kind of marble in our laboratories, so illustrating the process by which marble was naturally produced when vast masses of limestone sank down far beneath the earth's surface and were exposed to the central fires under the immense pressure of miles of superincumbent strata.

34. PALÆOLITHIC INSTRUMENT
From the gravels of Swanscombe, Kent

False Stratification. It is not necessary to enter into a detailed account of the various metamorphic rocks, which can be arranged in a long series, where every term shades into the next one, from the argillaceous *schists* closely resembling slates to the *gneisses* which can often be distinguished from granite only with difficulty. It is enough to say that these rocks are in general characterised by a double set of qualities which stamp them as intermediate between igneous and sedimentary rocks. They are crystalline, and they are arranged in layers or strata. Close examination betrays a typical distinction between these strata and those which mark the true sedimentary or stratified rocks. In the latter case the strata, or bedding-planes, indicate the successive layers in which these rocks were deposited by water or other agency. In the metamorphic rocks the stratification is produced in quite a different way. It is found by experiment that if a mass composed of crystals be subjected to powerful and long-continued pressure in a particular direction, the crystals which compose it tend to rearrange themselves so that all their longer axes lie in the same direction—just as the dates which have been squeezed into one of the lumps familiar in all grocers' shops are found to lie practically all in one direction. It is this rearrangement of the separate crystals which produces a false appearance of stratification in the metamorphic rocks.

Schists. A crystalline rock which has thus obtained a stratified structure as the result of pressure is known as a *schist*; it is often spoken of as being *foliated*, rather than stratified. A schist may also be the product of heat or chemical action upon a sedimentary rock, which gains a crystalline character without losing its stratified appearance. Practically all metamorphic rocks owe their origin to one or other of these causes.

The Schists are almost as numerous as the sedimentary and igneous rocks from which they are derived. Thus we have *clay-schist* and *quartz-schist*, which are both crystalline forms of clayey and sandy sedimentary rocks, while *quartzite* is a still more thoroughly crystallised sandstone. *Schistose conglomerates* are conglomerates in which pressure has produced a bedded structure by the arrangement of the pebbles into layers. *Crystalline limestone* and *marble* are also of sedimentary origin. *Gabbro-schist*, *hornblende-schist*, *mica-schist* and the like need little explanation. *Gneiss* is the term applied to the coarse schists which present characters resembling those of granite, some of which are volcanic rocks which have acquired a stratified character by alteration under pressure, whilst others are sedimentary rocks which have been crystallised by heat. This shows very prettily how diametrically opposed histories can end in nearly the same result in the great laboratory of Nature.

We shall now pass on to the second great division of geological study—*physical geology*, or the examination of the agencies at work to produce the sedimentary rocks which now cover the greater part of the earth, and give us our soil.

HYDROSTATICS

The Pressure of Liquids, and its Mechanical Application. The Hydraulic Press. Pumps of Different Types. Accumulators

By JOSEPH G. HORNER

The Two Kinds of Liquids. Matter exists in three forms—solid, liquid, and gaseous. Liquids and gases have no definite shape, and cannot, like solids, resist the action of forces impressed upon them. They are therefore called "fluids." *Hydro-statics* (Gr. *hydro* = water, *statikos* = static, or standing), strictly speaking, deals only with non-elastic fluids—*i.e.*, liquids. Water is so slightly compressible that a pressure of 22 atmospheres (324 lb. per square inch) merely diminishes its volume by a thousandth part. There are widely varying degrees of resistance to change of shape among liquids. Water, chloroform, and alcohol move very freely and are called mobile liquids, but oil, tar, pitch, treacle, and honey move very, very leisurely, and are called viscous liquids. As this, however, is only a question of degree of friction between the particles composing the liquid, and as viscous liquids behave like mobile liquids if they are given sufficient time, this distinction is of little consequence in questions concerning the equilibrium of liquids. A perfect fluid would be one in which friction between the particles was non-existent, and in which there was therefore no resistance to alteration in shape. A moment's consideration would show that as a consequence of this the pressure of a liquid at any point of a surface on which it acts is always perpendicular to that surface at that point. Hence, in constructing embankments, dams, docks, and so on, the pressure of the water has to be considered as acting in the direction of the arrows shown in the three cases in **128**, **129**, and **130**. The pressure is always perpendicular to the surface of the wall, and if the latter be not strong enough, it will be pushed along on its base, overturned, crushed, or lifted, as the various arrows indicate.

How Engineers Use Water. The engineer may be said to regard and to use water in two ways. Pascal, over 200 years ago, investigated the behaviour of water under pressure, and a century later that marvellous inventor, Joseph Bramah, produced his hydrostatic press, the action of which is based on the great law Pascal discovered. The modern hydraulic press, capable of exerting anything up to 12,000 or 14,000 tons pressure, and under whose action steel yields like clay, is an illustration of one of the ways in which engineers use water—by communicating pressure to it in such a way that that pressure, as we shall see later, is enormously magnified. Secondly, water possesses of itself a huge power, due to the force of gravity. Sometimes this is utilised, as in water-wheels and turbines, and in the equivalent form of the accumulator, but just as often it is a force which the engineer is called upon to neutralise, as in the construction of dams, lock gates, and retaining walls.

The Principle of the Hydraulic Press. Pascal, that mystic and fascinating scientist, found that liquids possessed the property of transmitting equally in all directions pressure exerted at any point on their surface. This is well illustrated by the apparatus in **131**. The closed vessel, the shape of which is immaterial, is filled with water, and at different points in its surface are cylindrical openings fitted with pistons. Piston B = twice the area of A; C = three times A; D = four times A. Now, according to the law just stated, any pressure communicated to the water by a piston will be transmitted with undiminished intensity in all directions inside the vessel. If the other pistons had the same area as A, and the latter were pressed inwards with a pressure of 40 lb., B, C, and D would each be forced outwards with a pressure of 40 lb. (in addition, of course, to the pressure previously sustained from the water itself). But as the area of each piston is double that of the preceding one, this 40 lb. pressure at A would become 80 lb. at B, 120 lb. at C, and 160 lb. at D. As the area is multiplied, so is the power. The same law is illustrated in the apparatus known as hydrostatic bellows or hydrostatic paradox [**132**]. AB and CD are circular boards connected by leather bellows; the tube E opens into the interior of the apparatus, and through it water is poured until the bellows are distended as far as it is possible. Heavy weights—even the weight of a man—may be placed on AB, and supported by the weight of the small column in the tube. In this way AB could be made to raise and support a hundredweight if the tube held 1 lb. of water and the area of AB were 112 times that of the tube. It must not be forgotten that this multiplied transmission of pressure is entirely due to the incompressibility of water.

How Hydraulic Presses Work. We are now able to understand the action of that wonderful machine, the hydraulic press, as it is constructed to-day, or, as it is sometimes called, Bramah's press, from the name of the inventor who devised its principle of operation. A [**133**] is a force pump which, operated by the lever handle B, pumps water from the chamber C, through the pipe D, into the strong cylinder E, thus forcing upwards the ram F. Let us consider its working in detail. On raising the handle B, the plunger P is lifted, the valve G at the bottom of the cylinder A is raised, and water enters from the reservoir C. On pressing down the handle B, the valve G closes, and another one (not shown) opens in the pipe D, through which the water is then forced. (An enlarged, detailed view of a pump of this type is shown in **144**.) Imagine this to be continued until the cylinder E is full. When this occurs, we have a state of affairs analagous to that just described in the hydrostatic bellows. The pressure imparted by the plunger P is transmitted undiminished to the piston F, but owing to the greater diameter of F over P this pressure is enormously magnified, and is multiplied in the ratio of the areas of the two cylinders. If the diameter of the plunger P be ¼ in., and that of the ram F 10 in., the ratio between their areas will be as 1 : 1,600. Therefore a pressure of 1 lb. on the plunger becomes an upward thrust of 1,600 lb. on the ram. If W = load or weight supported, and P = the load on or force applied to the plunger, then $\frac{W}{P} = \frac{D^2}{d^2}$, D being diameter of ram, and d diameter of pump plunger. From this formula it is clear that the mechanical advantage could be theoretically increased so as to produce an enormous multiplication of force—merely by increasing the ratio of the areas of plunger and ram. But in practice it is found that the strength of the sides of the cylinder necessary to sustain such great pressure places some limit to the power which might be obtained from the application of this law of transmission of pressure.

How Gravity Affects Liquids. Turning now to the pressure water exerts owing to its weight, a very important law runs as follows: *The pressure at any given depth depends directly on the vertical depth below the surface.* This, of course, is self-evident. The liquid may be considered to consist of horizontal layers, those at a great depth sustaining all the layers above. The weight of a cubic foot of water is 62½ lb., and this would be the pressure on an area a foot square at a depth of 1 ft.; at a depth of 2 ft. the pressure would equal 2 × 62½ or 125 lb.; at 6 ft., 6 × 62½ or 375 lb.; at D ft., D × 62½ lb. If instead of a base of 1 sq. ft. the surface pressed contained A sq. ft., then the total pressure P = D × A × 62½ lb. If the liquid in question be not water, its weight per unit volume (W) would be substituted for 62½, and P = D × A × W.

Strange as it seems, the pressure of water on the base of a vessel is entirely independent of the *quantity* of water the vessel contains. The pressure on the base of a full decanter would be the same if its sides were vertical or tapered towards the mouth like an inverted funnel instead of bulging, as long as the area of base and depth of liquid remained unchanged. Yet in one case it might hold a quart, in the other a pint.

In measuring the pressure of water against dams, etc., the formula P = D × A × 62½ will not be correct, for, as the pressure varies with the depth, an *oblique* or *vertical* square foot or yard will not have uniform pressure all over its surface; the part nearer the surface sustains less than the deeper parts, and this explains why in cast-iron water reservoirs and tanks, and in foundation caissons, the lower plates are made thicker than the upper ones. It is necessary to take the average pressure, and this is equal to the pressure at the centre of gravity. So the rule for finding the pressure against any surface becomes P = Area of surface pressed × vertical depth of the C.G. of the surface × 62½. Let it be required to find the total pressure against the retaining wall in **134**. Suppose the wall 30 ft. long, and the depth of water (E), 20 ft. The wetted area therefore = 30 × 20 = 600 sq. ft. The vertical depth of the centre of gravity of the surface pressed below the surface of the water is in such a case half the depth of the water, or 10 ft. Hence the total pressure against the wall = 600 × 10 × 62½ lb. = 375,000 lb. = over 167 tons.

Retaining Walls. We have seen in the preceding paragraph how the total water pressure against a retaining wall may be estimated. In calculating the thickness and weight of wall necessary to prevent it being overturned or fractured it is convenient to consider this total water pressure as concentrated at one particular point in the wall, which is called the *centre of pressure*. It is the point at which the resultant of the fluid pressures acts, and these pressures constitute a system of parallel forces with a resultant equal to the total pressure. If an equal and opposite force—*i.e.*, the equilibrant—were applied at this spot, the surface would be kept in equilibrium. A concrete example will render this clearer. Imagine a long, narrow trough or cistern, one of whose ends, instead of being fixed, is free to slide along the length of the trough. If the trough be filled with water the movable end will be forced right out unless it be kept in position by the pressure, say, of the thumb. Now, if the thumb be applied near the top of the surface the water would push out the lower part, and if applied at the bottom, the water would force the upper part outwards. But there is a certain point at which the counterbalancing pressure might be applied, so as to keep the loose end in position and sustain the water pressure. That point is the *centre of pressure*. In the case of a horizontal area the centre of pressure coincides with the centre of gravity, but in the case of a sea-wall, where pressure increases with every unit of depth, it lies below the centre of gravity, and is found to be at two-thirds of the vertical depth below the water surface.

In **134** the pressure P is concentrated at the arrow head, one-third up from the bottom, and it acts in a horizontal direction. P will tend to overthrow the wall by making it turn about B, the moment of the water being P multiplied by BD, the latter in this case being one-third of the depth of the water. The moment of stability of the wall is the product of its weight (concentrated at its centre of gravity G), and the distance AB. If the moment of the wall be less than the moment of P, the wall will be overturned by the pressure of the water. (Generally, in calculations of this sort, the wall is assumed to be one foot in length, so that the total square feet of area of its vertical section also represents the cubical contents, and when multiplied by the weight of a cubic foot of the material of which the wall is composed, the total weight is obtained.) In actual practice retaining walls are made thicker than the overthrowing moment demands, especially where waves have to be considered. And as regards the form of the wall, although it is found that the stability is greater when the water presses against the sloping side, yet the danger of crushing and fracture often renders it advisable to sacrifice a degree of stability and let the vertical side receive the pressure.

Specific Gravity. Before touching the question of flotation and buoyancy it is necessary to have an exact notion of what is meant by specific gravity. The specific gravity (abbreviated sp. gr.), of any body is its weight, as compared with that of an equal bulk of water, though of course any other substance would serve as a standard of comparison. In the case of gases, air or hydrogen is the standard or unit. Now, as the volume of water or any other kind of matter changes with alteration in temperature, it is necessary that one particular temperature should be decided upon. As water has its greatest density at 4 degrees C. (39·2 deg. F.), that is the temperature generally adopted. Frequently, however, specific gravities are measured at the more convenient temperature of 60 degrees. A cubic centimetre of water at 4 deg. weighs 1 gramme. With this, then, as a unit, the sp. gr. of any substance is its weight in grammes per cubic centimetre. When we say that the sp. gr. of gold is 19·25, copper 8·7, lard ·95, wine ·9, Bath stone 2·1, alcohol ·79, cork ·24, we mean that these figures represent the weight in grammes of a cubic centimetre of these particular substances; or that the weight, say, of a cubic foot of gold is 19·25 times the weight of a similar volume of water, and that the ratio between the weights of a cubic foot or inch of cork and water is as ·24 is to 1.

The specific gravity of a substance not acted on by water and of greater sp. gr. than water can be found by weighing it first in air, and then in water, and dividing its weight in air by the loss of weight in water. If A = wt. in air, and a = wt. in water, then

$$\text{Sp. gr.} = \frac{A}{A - a}.$$

If a substance weighs 54·3 grammes in air, and 47·8 in water, its

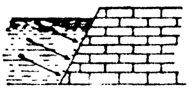
$$\text{Sp. gr.} = \frac{54\cdot 3}{54\cdot 3 - 47\cdot 8} = \frac{54\cdot 3}{6\cdot 5} = 8\cdot 3.$$

If the body floats in water, this method is useless, and a weight called a sinker is attached to the body, which is specifically lighter than water, to make it sink. If A = weight of body in air, B = weight of sinker in air, a = weight of body and sinker in water, b = weight of sinker in water, then the sp. gr. of the body $= \frac{A}{A - a + b}$. Specific gravity may be calculated in several other ways, but by means of an instrument called a hydrometer the sp. gr. of any liquid may be rapidly determined by noting on a graduated scale the depth to which the instrument sinks. With Nicholson's Hydrometer the sp. gr. of either a liquid or a solid may be found.

Buoyancy of Liquids. If a man plunges into a river, or a stone be thrown into a pond, a bulk of water is displaced exactly equal to the bulk of the body which enters and is immersed in the water. If it be partly immersed, as in the case of a ship, or a man floating, then the bulk of water displaced equals the bulk of the immersed portion only. That is quite obvious. Whether it be a case of total or partial immersion, two forces act on the body: that of gravity, which tends to make it sink to the bottom, and the upward force of the water tending to thrust the body upwards to the surface. Whether the body shall float, or sink to the bottom, or remain stationary at a certain depth, depends on the relative intensities of these two forces.

Over 2,000 years ago Archimedes stated the law governing the amount of upward pressure to which a body is subjected when placed in a liquid. He found that *a body immersed in a liquid is buoyed up with a force equal to the weight of the liquid it displaces.* If a cubic foot of the liquid weighs the same as a cubic foot of the solid—*i.e.*, if their specific gravities are the same—the body would remain at rest at any depth; if, as in the case of lead, the solid is specifically heavier than the liquid, the weight of the solid is greater than the weight of the displaced liquid and will sink. And the force with which it will descend equals the difference between their specific gravities. Thus, the specific gravity of lead is 11·38, so that with a cubic foot of water weighing 62½ lb., and a cubic foot of lead weighing 709 lb., the force with which lead would sink is 709 − 62·5 = 646·5 lb. In the case of a light substance such as cork or wood, its weight will be less than the weight of water displaced, and so it will be buoyed upward with a force equal to the difference between the weight of the displaced liquid and the solid. From this it is evident that a floating body such as a cork or a ship displaces its own weight of the water it floats in. Therefore the weight of any floating body may be easily calculated, for it equals the volume of water displaced, in cubic feet, multiplied by 62½ lb. Conversely the draught can be found if the weight and dimensions of the body are known.

The fact that a swimmer cannot sink in the Dead Sea, and that coins, stones, etc., float easily on mercury, is easily explained by the principle of Archimedes. The sp. gr. of Dead Sea water is 1·2 as compared with ·89 for the human body (alive). A living person would thus displace a quantity of water of greater



128

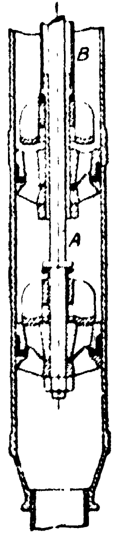
141



142

weight than his own body and hence would be thrust upwards till he reached the surface. The sp. gr. of mercury is 13·58. A cubic foot of mercury weighs over 7½ cwt., but there are very few solids a cubic foot of which would weigh so much. Therefore, when immersed in mercury they displace a volume of the liquid of considerably greater weight than their own and so rise. Even when floating, the solid will only displace its own weight of mercury, and hence in many cases only the slightest fraction of a solid will sink below the surface.

The Metacentre. The stability of a floating body depends on the position of that important point called the metacentre. In a ship, for example, the position of this point means all the difference between regaining the vertical, and capsizing when rolling in a rough sea. The two forces which keep a floating body in equilibrium—(*a*) the downward force of gravity and (*b*) the upward pressure of the water (equal to the weight of water displaced)—may be considered to act (*a*) through the centre of gravity of the body, at G in **135**, and B, which is the resultant of all the upward and parallel pressures through the centre of gravity of the water displaced at B. This latter point is called the *centre of buoyancy* and the line joining G and B is the *axis of flotation*. Now if a force be applied to the floating body so that it heels over as in **136**, **137**, the centre of gravity of the water displaced will be shifted, as shown, and the point M where a vertical line from the new centre of buoyancy cuts the axis is the *metacentre*. It is important to remember that the pressure of the water acts upwards in the direction of this line. In **135** G and B are in the same vertical line, and the body floats in equilibrium. If it be disturbed, B will change its position with every change in the position of the body, but if, as in **136**, the point where the vertical line from B cuts the axis lies above the centre of gravity, the upward thrust, acting in the direction of this line, will tend to make the body regain its former position. It is then said to be in "stable" equilibrium. But should this metacentre fall below the centre of gravity [**137**], the force acting through BM will tend to make the body depart still more from its original position until it finds a new position of equilibrium. This, of course, means upsetting or overturning, and is termed "unstable" equilibrium. It may happen that the relative positions of B and G are not changed by the disturbance of a floating body, and that the line BM meets the axis of flotation always at G. This is so in the case of a sphere or a cylinder turning on its longitudinal axis. We then have an example of "indifferent" or "neutral" equilibrium. Ships are ballasted in order to bring the centre of gravity so low down that the metacentre shall always be above it.

Practical Examples. In selecting practical examples of hydrostatics, far more must be omitted than can be illustrated, because the applications of water power are so numerous and important. They occur in shops and factories, in docks and harbours, in warehouses and stores, in small and large installations. They are used in many trades, and are more adaptable to some operations than any other power agency, while in some they have an absolute monopoly. Water power is silent and strong, silent though squeezing white-hot steel with a pressure of 8,000, 10,000, or 14,000 tons, or while opening the huge gates of docks, or pressing hay and fodder into bales, or lifting a trifle of 100 tons. It is capable, too, of the most precise and minute regulation within fractions of an inch, by the control of the water supply. In some spheres of action it is being ousted by electricity, but a wide and undisputed field is still retained by water. The principle underlying all this great group of pressure machinery is that of difference in areas, embodied in the old Bramah press, and its modern equivalent [**133**]. Pressure is proportional to area, so that the elements of design are absolutely simple. The difficulties which arise are those of risk of leakage, those due to friction—which is considerable—and the necessity for securing ample strength in cylinders subjected to pressures that ordinarily range from 700 to 1,500 or 2,000 lb. on every square inch, or still more in some cases.

Head of Water Unnecessary. The problems of *head* of water have been considered in previous paragraphs. But the machinery in question does not now utilise natural head in order to obtain pressure, though that was done in the early days of the hydraulic cranes. Not until Armstrong invented the accumulator did the success of the water pressure system become assured. This consisted originally of a large cast-iron cylinder fitted with a loaded plunger to impart pressure to the water. At once the gravity pressure of some 60 lb. to the square inch was abandoned for 600 lb. In an ordinary hydraulic plant, therefore, we have three elements—the accumulator for water storage under pressure, the force pumps and engines, by which the pressure is produced, and the working cylinder, or cylinders and rams, by which pressure and movement are applied to any particular mechanism, and which occurs in an immense number of forms.

The following is a very concise summary of *hydrostatic* mechanism, or, as it is commonly termed, *hydraulic* machinery.

At the basis of it all lies the pump in some form or another. The common lift or suction pump of wells and tanks plays but a small part here, but combined with another form, the plunger, it is a valuable agent for lifting water from great depths. Few mechanisms are varied more than are lifting-pump valves. A complete study of these would require a big volume. Deep and shallow wells, different kinds of liquids, clean or dirty, hot or cold, questions of accessibility, and so on require modifications in valves.

Pumps. The pumps of the hydrostatic group are very broadly divisible under two heads, the lift or *suction* type, and the *force* pump. The important distinction between the two is that the first-named depends for its action on atmospheric pressure, and the second does not. It is usual to include these under the pneumatic branch of mechanisms, because the atmospheric pressure exercises an essential influence in the operation of the suction type. But it is more convenient, from the point of view of practical applications, to dispose of them here.

The suction group, and the pressure group are found in many and varied designs. The first are limited to depths of water of about 24 ft., the second have practically no limitations. These, the *force pumps*, as they are called, are the ones that are invariably employed for pressure purposes, since there is no limit to pressure possible, save that of the strength of the bodies, and fittings, and valves of the pumps themselves.

The air enters into the operation of all pumps, only in the suction pump it is far more important than in the others. The point in the first-named is that there is nothing but the atmosphere as the acting agent, its pressure alone forcing the water up through the suction pipe and barrel, through the delivery valve. The limiting height is that from the delivery valve at the top of its stroke to the water-level in the well.

Suction Pumps. Figs. **138—142** are a selection of the essential mechanisms of various suction pumps. Fig. **133** is the common lift, or atmospheric pump in its most familiar form, with bucket A, having a hinged leather and metal-plated valve, and the clack B, also of leather, hinged and weighted with metal plates. The clack is prevented from rising too high by the stop piece C, as shown in **139**. Leakage past the bucket is prevented by the leather packing D. Fig. **140** is a form less liable to get out of order than the one with leather fittings, besides being suitable for liquids that would destroy leather. The bucket-valve A, and the clack-valve B, are of the mushroom form—direct lifting. Both are prevented from lifting too high, A by the arch of the bucket, and B by the perforated plate C. If one of these valves opens to a height equal to one-fourth of its diameter, it will pass all the water of which it is capable.

A design often preferred is that with ball valves [**141**]. The advantage of these is that they will not only lift, but rotate slightly and constantly on their seatings, so equalising wear. Sometimes the mushroom valves in **140** are made with their wings disposed spirally, to cause them to turn slightly on their seatings at each lift. The height of lift of the ball valves [**141**] is slight, and each valve is enclosed in a cage with open sides, through which the liquid escapes. The example shown is one by Hayward, Tyler & Co., for deep wells.

The theoretical height of 34 feet can never be reached, due to leakages past the valves, and these may be so great in pumps having badly packed valves, or dried leather valves, as to prevent any lift of water until the leakage has been overcome by "fetching" the pump with water. The atmosphere at the commencement of pumping occupies the suction pipe. On lifting the bucket, the air expands, with loss of pressure, and the external air forces water up to occupy a portion of the vacuum. When the bucket has been lifted and depressed a few times, no free air is left, and the pump lifts solid water.

Air-pumps are also suction pumps. They draw the condensed steam and vapour mingled with air from the surface condensers of steam-engines. They are a group by themselves, having little resemblance to the pumps just noticed, though based on the same principles. Like these, too, though atmospheric pumps, they lift water charged with air when in full operation.

The first thing one notices about the action of the suction pump is that it discharges water only on the lifting stroke, or intermittently. This is objectionable for feeding purposes, and hence we have the treble-barrel arrangement. In this, three pumps are set side by side, each complete in itself, but driven from a common crank shaft, the cranks of which stand at 120° apart. Practically, a continuous delivery is thus obtained. In such pumps, the handle is discarded for a belt, or engine drive. Except for agricultural and domestic purposes, the lever handle is seldom used for pumps, but some form of power drive is applied.

Another way in which a practically continuous stream is obtained is in the double-action pump [**142**]. Here, the rod A of the lower bucket passes through the rod B of the upper one, and both are crank driven in such a way that the buckets move in opposite directions, one lifting while the other is forcing, a partial vacuum being formed between the buckets. The bottom bucket takes the place of the fixed valve in the previous figures.

Force Pumps. In these, a solid plunger or ram is substituted for the bucket with a valve, or valves, and the delivery valve is in a portion of the pump body away from the ram. The ram, therefore—a solid piston—alternately creates a vacuum into which the water flows through the suction valve, and then forces it through the delivery valve. Water can be raised through great heights thus, or what is equivalent, against great pressures, as when used for pumping into steam boilers. Also, the ram being independent of the valves, it may occupy either vertical, horizontal, or angular positions. This pump is also intermittent in action, delivering its water in a series of impulses, unless mounted in three-throw style, or fitted with an air vessel.

Plunger and Bucket Pump. There is another way of obtaining a continuous supply—namely, by the combination of a ram plunger with a bucket. Here, a bucket A, with valve, lifts the water, but on the down stroke the ram B displaces a volume of water equal to its own, and sends it out through the delivery valve C. Water being, therefore, discharged during both strokes, the supply is continuous.

Double-acting Pumps. Though the foregoing pumps may be made to yield a continuous supply, yet they all suck water on one stroke and discharge it on the next, and are, therefore, nominally single-acting. When good duty is required, such designs are too wasteful, and then pumps that suck and discharge on each stroke are designed, hence termed double-acting, or duplex pumps. There are a good many of these. The two best-known forms are that in which a single piston operates two sets of suction and discharge valves arranged at opposite ends of a common chamber, and the Worthington type. In this, two pump chambers and engine cylinders are arranged side by side. The steam piston and pump pistons are at opposite ends of their rods, and the slide valves are operated by the piston of the fellow-engine. The pumps draw from a common suction pipe, but each chamber has its own suction and delivery valves. An air vessel is common to both.

The Test Pump, or Hydraulic Force Pump. This is a ram pump [**144**] indicated in connection with the press [**133**], in which the water, practically incompressible in itself, is forced by a single-acting solid piston through valves and passages against the resistance of the work to be done. The latter may be anything, but is essentially a mass resistance. It will be observed that the valves bear but a small proportion to the mass of metal in the body of the pump, which is usually specified to be strong enough to resist a pressure of 2,000 lb., or more in some cases, to the square inch. The body is of gun-metal, as are also the suction and delivery valves A and B. The ram C is actuated by the lever B [**133**], and the water flows out through the passage indicated by the arrow. D is a relief valve for releasing the pressure by the lever seen above, the pressure water flowing away *through* E. *The perforated rose,* F, *prevents any solid particles getting into the valves. The relation of this to the common force pump,* one form of which is shown in **145**, will be obvious. The ram and valves are there, but the proportions are different, the pump [**145**] being suitable for pressures of from about 60 to 100 lb.

Air Vessel. The air vessel mentioned just now is not used on test pumps like **144**, because the volume of water pumped is extremely small, and has not to traverse far. In other words, there is no chance for the water to become saturated with air. But for long deliveries and for moderate pressures the air vessel is essential. One form is seen in **146**. It is made with a spherical end to ensure strength. Sometimes water will find its way through the pores of inferior qualities of iron. This vessel [**146**] is a chamber of large dimensions, fitted somewhere on the delivery side. It contains air, which, being elastic and compressible, becomes a cushion to the water that rises a little way into its neck during the delivery stroke. When the backward non-delivery movement takes place, the air, thus compressed, forces down the water that had invaded the chamber, sending it along after the rest, so that a practically continuous stream results.

Simple examples of the utilities of the test pump [**144**] are the testing of steam boilers, and steam and water pipes, or the lifting of a baling press. The resistance is that of the metal in the first, or of the material to be compressed in the last. As the water will not yield, the tug-of-war lies between the strength of the pump on one side and that of the boiler, or pipe, or press on the other. Then there is the utility of the pump for charging accumulators. As there comes a time when something would have to yield, the pressures are recorded on a dial gauge, and the pumps are fitted with relief valves. An advantage of these pumps is that the pressure may remain on for several hours, which is often a severe trial of strength of a boiler. These pumps occur in many forms, some being operated by hand levers, others directly connected to steam engines or electric motors.

The Accumulator. As pumps are too slow in operation for rapid work, the accumulator [**147**] is fitted where rapid action is required. For example, imagine how slow would be the movement of a hydraulic lift at a railway station if it were actuated directly by a pump; and the movements of a crane, also, or of a steel ingot press, or of a flanging press. In such cases the pumps fill the accumulator until it is charged with many gallons of water under a pressure of from 700 to 1,500 lb. per square inch, the latter being equal to 100 atmospheres. On opening communication between the accumulator and the lift, or crane, or press, the pressure-water works it at a speed capable of regulation. The pressure or resistance of the accumulator is obtained by loading its casing with weights to the 700 or 1,500 lb. required per square inch.

In **147** the parts are as follows: The pressure-water entering at A raises the ram B in the cylinder C, standing on the base H. The cross-head D attached to B, rising with it, receives rod E, on which is hung a plate, F, carrying a number of circular weights, G. The water being pumped, therefore, has to overcome the resistance of these weights, which, when raised, become the source of stored-up energy for doing work by their descent. The water passes to the machine, being operated through a tube (not shown) similar to A. The weights are made removable to permit of regulating the pressure according to the number used at any time. For convenience, it is arranged that each weight makes a difference of 100 lb. in the pressure. In the older accumulators, and in many at present, a casing of sheet metal (the weight-case) is used instead of F, and loose stone or iron is loaded in. The advantage of this is that the expense and trouble of transporting weights is avoided, since any rubble may be used on the spot. The cast weights already mentioned provide a convenient means of regulating the pressure with precision, as stated.

We have now to note some of the common applications of the hydrostatic press and accumulator to manufactures and industries, which will occupy the next article of this course.

PRACTICAL GEOMETRY & OBJECT DRAWING

Inscribed and Circumscribing Figures. A Lesson in the Drawing of the Skeleton Cube and Vases; with a Note on Memory Drawing

By WILLIAM R. COPE

INSCRIBED AND CIRCUMSCRIBING FIGURES

284. About a Given Triangle *ABC*, to Describe another Triangle similar to a Given Triangle *DEF*. On *AB* construct a triangle similar to the triangle *DEF*. Through *C* draw a line parallel to *AB*, and produce *GA*, and *GB* to meet it. Then *GHJ* is the triangle required.

285. About a Given Square *ABCD*, to Describe a Triangle similar to a Given Triangle *EFG*. On *AD* construct a triangle similar to *EFG*. Produce the sides to meet *BC*, produced as shown.

286. Within a Given Triangle *ABC*, to Inscribe another Triangle similar to a Given Triangle *DEF*. On *AB* construct a triangle similar to *DEF*. Draw *GC*. From *H* draw *HJ* and *HK* parallel to *GB* and *GA* respectively. Join *JK*. Then *HJK* is the required triangle.

287. To Inscribe an Equilateral Triangle in a Given Square *ABCD*. Draw the diagonal *AC*. On *AC* construct an equilateral triangle *ACE*. From *D* draw *DF* and *DG* parallel to *EA* and *EC* respectively. Join *F* and *G*.

288. To Inscribe a Square in a Given Triangle *ABC*. Draw *AD* perpendicular to *BC*. From *A* draw *AE* parallel to *CB* and equal to *AD*. Draw *EC*. From *F* draw *FG* and *FH* parallel to *BC* and *AD* respectively. From *G* draw *GJ* parallel to *AD*. Then *FGJH* is the required square.

289. To Inscribe a Square in a Trapezium *ABCD*. Draw the diagonals *AC* and *BD*. Draw *AE* parallel to *BD* and equal to *AC*. Draw *BE*. From *F* draw *FG* and *FH* parallel to *BD* and *AC* respectively. From *G* draw *GJ* parallel to *AC* and join *JH*.

290. To Inscribe a Square in a Given Sector *ABC*. Join *B* and *C*. Draw *CD* perpendicular and equal to *BC*. Draw *AD*, and from *E* draw *EG* and *EF* parallel to *CB* and *DC* respectively. Draw *GH* and *FH* parallel to *EF* and *EG*.

291. To Inscribe a Square in a Segment *ABC*. Bisect the chord *AB* of the segment in *J*. Draw *BD* equal and perpendicular to *AB*. Draw *JD* and produce it to cut the arc in *E*. From *E* draw *EF* and *EG* parallel to *DB* and *BA* respectively. Draw *GH* parallel to *EF*. Join *FH*. Then *GHFE* is the required square.

292. Within a Given Circle, to Inscribe a Triangle similar to a Given Triangle *ABC*. At any point *D* in the circumference of the given circle draw a tangent *EF*. Make the angle *EDG* equal to the angle *CAB* and the angle *FDH* equal to the angle *ABC*. Join *GH*. Then *DHG* is the required triangle. [Euc. IV. 2.]

293. About a Given Circle, to Describe a Triangle similar to a Given Triangle *ABC*. Produce the base *BC* of the given triangle. Find the centre *L* of the given circle, draw any radius *LG*, and produce it. Construct the angle *FLG* equal to the exterior angle *ACD*, and the angle *HLG* equal to the exterior angle *ABE*. Produce *LH*, *LF*, and draw tangents as shown. [Euc. IV. 3.]

294. To Describe a Square About a Given Isosceles Triangle *ABC*. Bisect the base *BC* of the given triangle by the line *AD*. On *BC* describe a semicircle. Then *AD* will be a diagonal of the required square. Draw *DC* and *DB* of indefinite length, and from *A* draw parallels to meet them.

295. In a Given Hexagon *ABCDEF*, to Inscribe an Isosceles Triangle, the Base *HJ* being Given. Draw the diagonal *AD* of the given hexagon. Draw *CE* at right angles to *AD*. Set off *EK* equal to *HJ*. Draw *KL* parallel to *ED*, and *LM* parallel to *CE*. Draw *AL* and *AM*.

296. Within a Given Circle, to Inscribe an Isosceles Triangle, the Base *AB* being Given. Draw two diameters of the given circle *CD* and *EF* at right angles to each other. Make *GH* equal to half the given base *AB*. Draw *HJ* parallel to *CD*, and *JK* parallel to *EF*. Draw *CJ* and *CK*. A similar method may be used for inscribing an isosceles triangle in a square, rhombus, or polygon.

297. Within a Given Square *ABCD*, to Inscribe another Square, one Angle to Touch a Side at a Given Point *E*. Draw the diagonals of the given square. With centre *F* and radius *FE* describe a circle. Join the points *E*, *G*, *H*, *J*.

298. To Inscribe a Rhombus in a Given Parallelogram *ABCD*, having One of its Angles at a Given Point *E*. Draw the diagonals of the parallelogram. From *E* draw *EF* passing through the centre *G* of the parallelogram. Through *G* draw *HJ* at right angles to *EF*. Draw *EJ*, *JF*, *FH*, and *HE*.

299. To Inscribe a Square in a Rhombus *ABCD*. Draw the diagonals, and bisect the angles thus formed. Join *E*, *F*, *G*, and *H*.

300. To Inscribe a Square in a Hexagon. Draw the diagonal *AB*, and bisect it at right angles by the diameter *CD*. Proceed as in 299.

301. To Inscribe a Regular Hexagon in an Equilateral Triangle *ABC*. Bisect each of the angles of the given triangle by the lines

INSCRIBED AND CIRCUMSCRIBING FIGURES

AE, *BF*, and *CD*. With centre *G* and radius *GA* describe a circle. Draw *DE*, *EF*, and *FD*. Then *HJKLMN* is the hexagon required.

302. WITHIN A GIVEN TRIANGLE *ABC*, TO INSCRIBE A RECTANGLE, THE LENGTH OF ONE SIDE, *DE*, BEING GIVEN. Set off *BF* equal to *DE*. Draw *FG* parallel to *BA*. From *G* draw *GH* parallel to *CB*. Draw *HJ* and *GK* perpendicular to *BC*.

303. IN A GIVEN SQUARE *ABCD*, TO INSCRIBE AN ISOSCELES TRIANGLE, THE BASE *EF* BEING GIVEN. Draw the diagonals *AC* and *BD* of the given square, and on *CA* set off *CG* equal to the given base *EF*. Draw *GH* parallel to *CB* and *HJ* parallel to *GC*. Draw *DH* and *DJ*.

304. WITHIN ANY GIVEN QUADRILATERAL *ABCD*, TO INSCRIBE A PARALLELOGRAM, HAVING GIVEN THE POSITION, *E*, OF ONE ANGLE. Draw the diagonals *AC*, *BD*. Draw *EF* parallel to *AC*, *EH* and *FG* parallel to *BD*. Join *G* and *H*. Then *EFGH* will be the required parallelogram.

305. WITHIN ANY GIVEN QUADRILATERAL *ABCD*, TO INSCRIBE A PARALLELOGRAM, HAVING GIVEN *EF*, THE LENGTH OF ONE SIDE. Draw the diagonals *AC*, *BD*. On one of them set off *BG* equal to *EF*. From *G* draw *GH* parallel to *BC*. Draw *HJ* parallel to *DB*, *HK* and *JL* parallel to *CA*. Join *KL*. The same method may be used for inscribing a rectangle in a square, rhombus, or trapezoid.

306. WITHIN A GIVEN TRIANGLE *ABC* OR ANY REGULAR POLYGON, TO INSCRIBE ANOTHER SIMILAR FIGURE, HAVING ITS SIDES PARALLEL TO AND EQUIDISTANT FROM THOSE OF THE GIVEN FIGURE, THE LENGTH OF ONE SIDE, *DE*, BEING GIVEN. Bisect the angles and obtain the centre *F*. Set off *BG* equal to *DE*. Draw *GH* parallel to *BF*, *HK* parallel to *CA*, *HL* parallel to *GB*, and join *K* and *L*. Then *HLK* is the required triangle.

307. ABOUT A GIVEN TRIANGLE OR ANY REGULAR POLYGON (SAY A HEXAGON *ABCDEF*), TO DESCRIBE ANOTHER SIMILAR FIGURE, HAVING ITS SIDES PARALLEL TO AND EQUIDISTANT FROM THOSE OF THE GIVEN FIGURE, THE LENGTH, *GH*, OF ONE SIDE BEING GIVEN. Find the centre as before, and produce the lines bisecting the angles. Produce *CD*, and set off *CK* equal to *GH*. Through *K* draw *LM* parallel to *DE*, and the other sides parallel to the respective sides of the given hexagon, as shown.

OBJECT DRAWING

Skeleton Cube. To many students the skeleton cube seems to be a very difficult object to draw correctly, and perhaps it is so, especially when it is in positions similar to that shown in **310**; but most, if not all, the difficulties will be overcome, if sufficient care is given to the preliminary but thorough analysis and observation of the model, before drawing a single line. For example, it will be seen that the edges may be divided into *three* sets—viz., first, a *vertical* set, secondly, all those vanishing to the *right*, and thirdly, those receding to the *left*, as in **308**. In **309** there are vertical and horizontal sets, with a third set receding straight away in front from the spectator. In **310** will be seen a set vanishing upwards to the right, another upwards to the left, and a third set downwards to the right. The above examination of the object ought to enable the student to make no errors in the direction and apparent convergence of receding parallel edges. Begin by drawing the appearance of the object as if it were a solid cube, as shown in small sketches in **309**, being very careful to keep the true relative apparent proportions between the different faces. Next, having noticed the proportion of the apparent thickness of the bars, sketch the vertical lines *AB*, *CD*, *EF*, and *GH*, which represent the bars of the vertical visible faces and then the lines *AC*, *BD*, *EG*, and *FH*, for the receding edges of the same faces. The top surface is then easily obtained by producing the vertical edges *BA*, *DC*, *FE*, and *HG*, to the top front receding edges *JK* and *JL*, and from the points *M*, *N*, *O*, and *P*, draw lines converging right and left with *JK* and *JL* in **308**. The next step is an important one, and that is drawing accurately the position of the edges *QR*, *HS* and *DT*, which should all intersect at *one* point *V*. If they do not do so, then the student may be certain that he has made a mistake previously in the convergence of the other edges, or the proportion of the faces. The rest of the drawing should be found very simple, especially if the student will notice the connection between the various edges as shown by dotted lines. In **309** will be seen an instance of very much foreshortening of the thickness of the inner surfaces of the bars; this will need special care. We must not forget that the edges *AB* and *CD* should appear to converge to the same point as the edges which recede at the top. The observer is supposed to be opposite the front vertical face of the cube, which is below the eye level. When the cube is tilted, as shown in **310**, we have a somewhat more difficult view to draw, but method and

will overcome the difficultie

the position of the nearest corner *A*, then the direction of the three lines radiating from it. Each of these lines belongs to a different set, and all others depend upon them for correctness in every respect, therefore great care should be given to deciding their apparent direction and length. The rest of the drawing is then as easy as in **308**, for the student has only to obey the rule of apparent convergence of receding parallel edges, and observe their relative proportions.

Vases. The vases chosen for models in this course are those to be found in all art schools, but other vases will do just as well for examples to study. Fig. **311** is a view of the vase known as the white bottle, **312** as the terra-cotta vase, and **313** as the red glazed one, all standing, of course, in a vertical position.

Beautiful Form of the Vases. The student should observe the great beauty of these vases, which is shown in the harmonious proportions between the various parts, and the subtle but charming and beautiful curves of the contour lines, etc. When the student perceives

319

LESSONS ON THE SKELETON CUBE AND VASES

the beautiful form of these objects he will not be likely to make a wrong and ugly drawing of them, as is too often done by unobservant, inappreciative, and careless beginners.

Method of Drawing Vases. When the vases are symmetrical in form and standing in a vertical position, as in **311-313**, begin by sketching the upright axis *AB* of the vase; then determine the greatest width, both as regards position and proportion, and draw the line *CD* to represent them, noticing carefully that it *appears at right angles to the axis AB of the object*. Next draw the major axes of the various ellipses, such as *EF*, *GH*, etc., again observing that the axes are always perpendicular to *AB*, and then fix the position of the narrowest part of the neck, such as *LM*. Now proceed to sketch the main contour lines and the curves for the ellipses, all the time endeavouring to realise the beautiful form of the vase, which sometimes requires the line to curve slowly and at others more quickly. Great attention should be given to the rims, bases, and mouldings, if any, observing the apparently greater width of the rim at the ends of the major axis, as in **312**. Notice the apparent connection (shown by dotted curved lines in **311**) between the neck and the base; the *elliptical* form of the body in **311**, the *oval* form of that in **312**, and the *circular* or *globular* shape in **313**. Do not make the very common error of drawing a horizontal straight line for the bases, for as these are really circular in shape and below the eye level, they must appear as parts of ellipses. The base can appear as a straight line, only when it is exactly level with the eye, and, if lying in an oblique position, when the *plane of the base* would pass directly through the observer's eyes.

Oblique Positions of Vases. These positions often cause great trouble to beginners, but very little should be experienced if the student will first of all draw the correct direction and length of the axis *AB* of the vase; and observe that the greatest width, the narrowest part of the neck, and the major axes of the ellipses are *always at right angles to the axis AB of the object*. The student should place the vases in such positions as shown in **314-319**, and verify the above laws. In these oblique positions of the vases, peculiar appearances of the rims, interiors, and bases will be noticed, and much careful observation will be necessary for the mind to perceive them. All the representations in **314-319** are those of the vases lying down *on a horizontal plane*, sometimes with the mouth, at others the base, towards the spectator. Figs. **315** and **318** are of special interest, for they are splendid views for finding out whether the student will draw what he *sees*, instead of what he *knows*. As stated before, the vases are lying *on a horizontal plane*, with the axis of the objects really slanting downwards away from the observer, yet this axis in each view shown in **315** and **318** *appears horizontal*; but it must be remembered that this is only so when the vase is turned away at *a particular angle*, for it is quite possible to have the axis of the object—when its base is towards the observer—apparently slanting downwards or upwards, and the student should make experiments with the vases in various positions.

General Observations. The student has now had all the main principles of object drawing explained to him, and the more practice he gets, the more he will find how often these principles are employed and what sure guides they are to the correct drawing of any object he may wish to represent. But he should not stop here, for there is still much to be done, and of much more interest, when light and shade and colour are involved. Yet tone and colour will not hide bad drawing—rather, they will emphasise it; therefore, it is most necessary to *learn to draw correctly*, which can only be accomplished by continual and regular practice. The student should carry a sketchbook and draw in it as often as he possibly can any object of interest that presents itself. If he cannot join an art school he should obtain criticisms and advice on his work from some friend who can draw, and should not be discouraged because his work may perhaps be adversely criticised, but, rather, he should be spurred on to do much better work.

MEMORY DRAWING

This is, without doubt, one of the most important branches of drawing, and should be cultivated as early as possible. It is a powerful stimulus to the imagination, besides being a means of cultivating confidence and self-reliance in the student. It has been said: "A visual image is the most perfect form of mental representation wherever the shapes, positions, and relations of objects in space are concerned. It is important in every handicraft. The best workmen are those who visualise the whole of what they are going to do before they take a tool in their hands."

Method of Procedure. To make true progress in this subject, as in all others, method is required. The student should begin by placing at a convenient distance and level some simple rectangular object, such as a box, book, stool, table or either of the rectilineal geometrical models used in object drawing, and make a most careful observation concerning their apparent general proportion and direction of receding edges, and not forget the important rule: "Draw what you see and not what you know." It is most essential that these main facts should be observed correctly and then the details will give little trouble. These observations may be finished in three or four minutes. Having marked the position of the object, so that it may be again placed in exactly the same position, remove the object from sight, and then make a fair-sized drawing of it from memory. Now replace the object in its former position and compare the drawing with it. The same procedure may be adopted with regard to curved and more difficult objects, such as a cup and saucer, a silk hat, etc. The student should practise regularly, and eventually he will be able to draw with ease from memory, flowers, plants, and even animals.

BILLS OF EXCHANGE

Advantages of Bills of Exchange. Distinction between Salaries and Wages. Dishonoured Bills. The Parties to a Bill

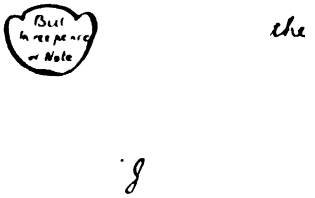
Continued from page 979

By A. J. WINDUS

Bills of Exchange. Transaction (*i*), September 22nd. Drew on J. Wake for £20 10s. 6d., at three months' date, in settlement of account to 19th September.

Strictly speaking, this is not a transaction, because there are not yet two parties to it. It has, however, been placed here as a convenient peg on which to hang a few remarks about bills of exchange, in order that we may the better understand transaction (*n*).

Paraphrasing (*i*), we might say that up to September 19th, J. Wake owed Bevan & Kirk £20 10s. 6d. For reasons not given, Bevan & Kirk desire to obtain written acknowledgment of the debt in a peculiar form called a bill of exchange. They therefore "draw" on Wake for the amount ; that is to say, they send him a written demand couched in the following terms :



But
Note
the

The above document is written on stamped paper. The cost of the stamp varies with the amount of the bill, as follows :

	Not over £5	1d.
Over £5	,, ,, £10	2d.
£10	,, ,, £25	3d.
£25	,, ,, £50	6d.
£50	,, ,, £75	9d.
£75	,, ,, £100	1s.
£100	One shilling per cent., and an extra shilling for any odd amount, thus a bill for £542 would carry a six-shilling stamp.	

The foregoing stamps are not adhesive, as postage stamps are, but are impressed beforehand on the paper on which bills and promissory notes are to be written. The work of stamping the paper is performed by the staff of the Inland Revenue Department, and stocks of bill paper, bearing stamps of various denominations, are issued to different post-offices throughout the kingdom, and to law stationers and others for sale to the public.

There is, however, an exception to these stamp duties in the case of certain bills. Any bill of exchange, no matter how large its amount, which is either payable on demand, or at sight, or on presentation, or within three days after date or sight, is allowed to escape with a nominal stamp-tax of one penny. That is why cheques, which, legally, are nothing else but bills of exchange drawn on a banker, payable on demand, are allowed to issue bearing penny Revenue stamps only. Not very long ago a Chancellor of the Exchequer tried hard to increase the tax on cheques to twopence for each cheque drawn, but business men and bankers manifested such determined opposition to the proposal that it was withdrawn.

Advantages of Bills. We are not told why Bevan & Kirk drew on Mr. Wake for the amount of this debt, but if we consider three of the reasons for creating bills of exchange, we may perhaps find that all three would apply in this instance :

1. A bill of exchange is a negotiable instrument.
2. It fixes beyond dispute the amount of the debt.
3. If dishonoured, it confers upon the holder a right of action, based upon the instrument itself.

The legal doctrine of negotiability has a far-reaching influence in commerce. For its fuller treatment the student is referred to the section on Commercial Law [see Law], but its practical effect will be noted in transaction (*n*) to follow.

With regard to the second and third points, the law presumes, until the contrary is proved, that all bills of exchange are given for value received, whether the phrase "value received" is present or not. In other words, a bill of exchange presupposes an existing debt on which the bill is founded. In the case before us, the pre-existing debt was one of £20 10s. 6d. due by J. Wake to Bevan & Kirk.

Spurious and Dishonoured Bills. Sometimes false or spurious bills, which are not founded on a prior debt, are created. These are known as *kites*, or accommodation bills. Frequently there is nothing whatever to distinguish them from genuine bills, and it is therefore an essential rule of law to put all bills upon an equal footing. Moreover, in the absence of any unusual circumstance, the law does not regard the question whether adequate consideration has or has not been given for a particular bill. For example: if Wake "accepted" the bill drawn on him by Bevan & Kirk—that is, if by signing his name across the face of the bill he promised to pay it at the due date, he could not afterwards refuse to pay it on the plea that he had since discovered moth in some of the articles he had bought from Bevan & Kirk. Therefore, we may say that a bill of exchange fixes beyond dispute the amount of the debt. Again, if, having accepted the bill, Wake dishonoured it by non-payment of the amount when it was due, the holder (not necessarily Bevan & Kirk) could sue on the bill alone for the full amount, plus the law costs. The law requires no further evidence of indebtedness than is supplied by the bill itself, and thus there would be no need to go to the trouble of proving delivery of the goods or their sound condition at the time when Wake's order was executed.

The Parties to a Bill. While there are three parties to a foreign bill, there are generally only two original parties to an inland bill—to one, that is to say, which is both drawn and payable within the British Isles. In Wake's bill, the two parties are apparently Bevan & Kirk, drawer, and J. Wake, drawee. But up to now we have no right to apply the term "party" to J. Wake, except in the sense of his being a passive or an involuntary party. Consequently, it is not until he becomes an active, or a consenting party, by accepting the bill drawn upon him, that we have a real transaction capable of being expressed in terms of double-entry. Accordingly no entry of (*i*) can be made in the books of account, although a copy of the letter which was sent to J. Wake covering the draft for acceptance, will be found in the counting-house letter book.

We pass on to the next:

> Transaction (*j*), Sept. 23rd. Paid salaries and wages as per salary book, £11 9s. 0d.

In a former paragraph it was stated that most of the staff of Bevan & Kirk were paid weekly. The junior partner personally attends to this matter. Every week he makes out, in a private memorandum book, a list of the weekly employés, placing opposite each name the amount due as salary or wages. The total being ascertained, the exact sum is drawn from petty cash and distributed by the junior partner. The memorandum book spoken of has been noticed under the name of salary book in our list of supplementary records. To assist those of an inquiring turn of mind in stifling their natural curiosity, the junior partner keeps this book locked up in his desk, and the weekly totals merely are entered as payments in the petty cash book (*q.v.*).

Distinction Between Salaries and Wages. There is a technical difference in meaning between the terms "salaries" and "wages" which merits a brief consideration. Let us suppose that the weekly total of £11 9s. 0d. for salaries and wages is made up as follows:

SALARIES.			
2 town travellers	6	0	0
Stockkeeper	1	1	0
Junior clerk		17	6
2 boys	1	1	0
	8	19	6
WAGES.			
3 girls	2	9	6
Total	£11	9	0

The broad distinction to be observed here is that *wages* relate to expenses of production (or buying), and *salaries* to expenses of distribution (or selling). Wages are expended either in manufacturing goods or in making them merchantable. Thus, the girls employed by Bevan & Kirk are engaged in assorting, under special selling or "call" numbers all goods received, repacking them in smaller quantities suitable for Bevan & Kirk's class of business, and so on. Their wages, therefore, are reckoned as addition to the cost of the purchases. The other weekly wages, whether "productive," as in the case of the town travellers, or "non-productive," as in the case of the junior clerk, are styled salaries, and treated as part of the fixed or establishment expenses of the firm.

> Transaction (*k*), Sept. 23rd. Paid Rice & Sons cheque, value £49 4s. 3d., in settlement of their account, £50 9s. 6d., less 2½ % discount

This transaction is the converse of (*h*), in which Bevan & Kirk *received* cash and allowed discount, whereas here Bevan & Kirk *pay* cash and obtain discount. Since the firm avail themselves of discount terms as often as possible, it will be convenient to have a column ruled on the right-hand side of the cash book on purpose to accommodate items of discount obtained. Each item is entered in a line with the cash item to which it relates. Thus, Bevan & Kirk paid away £49 4s. 3d to Rice & Sons in settlement of an account of £50 9s. 6d.—that is, they deducted £1 5s. 3d. discount, being 2½ % on the latter amount. As the cheque represents a payment made by Bevan & Kirk, the value of it is entered on the payment, or credit, or right-hand side of the cash book; and in a line therewith, on the same side, discount £1 5s. 3d. is entered in the discount column.

> Transaction (*l*), Sept 25th. Paid postage of parcel to Williams Bros., Cape Town, 5s.

It is usual to make such payments out of petty cash, and we shall accordingly expect to find this entered under the proper date in the payment column of the petty cash book (*q.v.*).

NURSE & GENERAL SERVANT

Duties and Daily Routine of the General Servant. The Cook-General. The Sewing-maid. Nurse and Under-nurse. The Daily Servant

Continued from page 1005

By A. EUNICE T. BIGGS

THE GENERAL SERVANT

The duties of a general servant are so numerous that unless she is very energetic and industrious she will find every moment of her day almost too fully occupied. She should be very strong, healthy, and active. If she is inclined to waste her time, or to be unwilling over her work, her duties will become very arduous. The work of a general servant is undoubtedly hard, but no harder in a small household than the work of another servant where there is a large family. She will, in all probability, be greatly assisted by the mistress of the house, and by the grown-up daughters, should there be any. The mistress will probably be down a good time before breakfast, making the tea, etc., and generally helping the maid to be punctual with the meal. Then, after breakfast, the former will probably assist with the making of the beds and the dusting. The drawing-room will be undertaken by the mistress or a grown-up daughter, both in order to lighten the servant's duties, and also because the furniture and the ornaments of a drawing-room need gentle handling. The rough work of a general servant naturally tends to make her hands less fit for such employment.

Morning Duties. The general servant should rise early in order to get through some of her work before the family are about the house. She should light her kitchen fire directly she comes downstairs, clean the hearth, rub up the range, and put the kettle on to boil for the breakfast.

She should then go to the dining-room and breakfast-room. After opening the windows, she should well sweep the carpet. If she is allowed the use of a roller-sweeper this will save much labour. Sweeping with a broom will then only be necessary from time to time.

She should remove the rug from the front of the fireplace, spread a large coarse drugget over the carpet, and proceed to remove the ashes, clean the hearth, and lay the fire. The tiles should be wiped over with a damp cloth, and the bars of the grate polished. The work of the general servant is considerably lightened in the summer when she has only the kitchen fire to re-lay. Fires make a good deal of dust and dirt, so that the rooms will need still more careful cleaning during the cold months of the year.

Breakfast. Having laid and lighted the fire, swept the carpet, and dusted the room, the servant should lay the table for breakfast. At the appointed time she will call the family, taking up hot water if required to do so. She should then clean such boots as will be wanted early, afterwards tidying herself before beginning her further duties. If the family breakfast late, she may find time to tidy up the drawing-room grate, clean the doorsteps, wash the hall, and sweep down the stairs before breakfast. In any case, these duties are next in her daily routine.

The general servant must endeavour to be methodical in her work, and to remember the many little details that add so perceptibly to the comfort of the family. For example, she should put the plates and breakfast dishes into the oven to heat in good time, so that they may be ready for breakfast. Then she will set about the preparation of the meal so that it may be served punctually.

After-breakfast Duties. This done she should take her own, which will not take very long; and while the family are finishing she should go up to the bed-rooms and strip the beds for airing.

The family will do well to be considerate in the matter of sitting long over breakfast. If the meal is unduly prolonged by unpunctuality or by thoughtlessness, it will throw out the servant's work and make her daily routine laborious.

Whilst the beds are airing, the servant should clear away and wash up the breakfast things. In this she will probably be assisted by her mistress if the family is numerous. The servant should then rearrange the kitchen, sweeping up the crumbs that have fallen on the floor during the preparation of breakfast, and putting away all utensils not in immediate use.

The mistress will then come into the kitchen and give her orders for the day. She will visit the larder and arrange with the servant as to the various meals to be served. In a small household the mistress will herself take active part in the cooking. Good food, tastefully prepared, and well cooked, is a great factor in the preservation of health, and on the health of the individual members depends not only the comfort, but also the prosperity of the family.

Daily Routine. Having received her orders for the day, the general servant returns to the bed-rooms. Either alone, or more usually with assistance, she makes the various beds. She then arranges the washstands, goes over the carpets with a roller or dustpan and brush, and finally dusts the furniture. This dusting is often consigned to a daughter of the house, and in many families, where there are grown-up daughters and only moderate means, each girl makes her own bed and dusts her own room. This considerably lightens the general servant's burden, and enables her to devote her energies to work from which it would be less easy to relieve her.

Having finished her routine work upstairs, the general servant will probably have some particular task to perform. For example, each bed-room must be "turned out" at regular intervals, either once a week or once a fortnight. Then the stair-rods will need carefully rubbing with polishing paste and leather, and in some houses a certain amount of washing has to be done at home. In most cases help from outside is occasionally hired by the mistress for particular parts of the work. For example, in turning out rooms and in washing, she will find extra help essential if the wheels of the household are to run smoothly. The hands of the general servant are often already so full that she cannot be responsible for further duties.

Preparation and Serving of the Mid-day Meal. After her morning's work, the general servant should wash her hands and put on a clean apron before laying the cloth for the mid-day meal. She should then put everything in readiness on the table and serve the food at the appointed time. She may either take her meal concurrently with, or after, that of the family. In the former case, she waits at table till all are served, and then goes to the kitchen for her own dinner. When the dining-room bell rings, she should answer it at once, remove the plates and dishes of the first course, and bring in the pudding. In houses where a general servant only is kept, the dinner will be served at mid-day.

When the meal is over, she should clear the table, dust and tidy the dining-room, re-make the fire, and brush up the hearth.

Afternoon Duties. Having finished her own meal, and rearranged the dining-room, the general servant must wash up the things used at dinner and during its preparation. Plenty of boiling water and soda will lighten her task. She then goes up to her room, changes her print dress for a black one, puts on a muslin apron and clean cap, and returns to the kitchen. If she is a quick girl, she will find herself free to sit down and sew for a short time before tea. After this little rest she will prepare and take in the tea, and then again her time will be unoccupied. Some afternoons she may devote to polishing the plate or brasses, others to turning out her kitchen cupboards and re-arranging them, or she may sew either for herself or for her mistress.

Evening Work. Tea being finished, the general servant should arrange the bed-rooms. She should close the windows—at any rate, partially—draw down the blinds, close the curtains, and see that dirty boots and shoes are taken away from the rooms. Lamps or gas should be lighted at dusk and passage windows closed.

If the family partake of an early tea, supper will be served during the evening. The meal will probably be of a simple character, not necessitating any cooking. After clearing it away, the general servant will have a certain amount of washing-up to do; she should then get everything in readiness for the night, and make certain preparations for the morning. She may put the breakfast china in readiness, being careful to cover the tray to protect it from dust, and she should see that there is a plentiful supply of coal, dry sticks, and paper for her fire-lighting operations of the next day.

THE COOK-GENERAL

Where two or three servants are kept, and the kitchen work is undertaken by one servant only, she is designated a cook-general. Not only is the cooking assigned to her, but various items of housework also. She is responsible for all the work of the kitchen, unassisted by a kitchen-maid, so she must keep the kitchen and scullery clean, wash up all cooking utensils, and polish up the copper and tin vessels and covers. The hall, stairs, and dining-room, or breakfast-room will doubtless be placed under her care; for these rooms she will be responsible. In small establishments the whole of the housework is often divided between a cook-general and a house-parlourmaid, the care of the bed-rooms and drawing-room, and the preparation for meals being undertaken by the house-parlourmaid, while the cooking and the care of kitchen, hall, and sitting-room are reserved for the cook-general.

THE SEWING-MAID

The sewing-maid is oftenest found in families where there are many young ladies, and where means are moderate. As the children grow beyond the age at which the services of a nurse are indispensable, the mother finds that some responsible person is necessary to help to keep their wardrobes in good order and repair. Perhaps the family income does not warrant the engagement of a lady's-maid, and a sewing-maid's services are therefore requisitioned.

Duties of the Sewing-maid. The sewing-maid will, to a certain extent, in such households, supplement the services of the house-maid. She will call the young ladies under her care in the morning, bringing in their hot water and drawing aside the bed-room curtains. She will, if required, help them when dressing. She may help with the process of hair-brushing and dressing, and with the fastening of frocks and blouses. The duties of the sewing-maid will vary widely in different classes of households. In most cases she acts as young ladies' or children's maid. Her privileges are not those of the lady's-maid, but her duties consist, like those of the maid, in personal attendance on the young ladies of the family. Occasionally, the sewing-maid may wait on the lady of the house instead of on the daughters.

Daily Work. The greater part of the day the sewing-maid will be busy with her needle. She should be very skilful in plain sewing, able to cut out and make all kinds of underwear, and having some knowledge of dress-making, in order to make simple clothes for her young mistresses. She should have good taste, and be able, if asked to do so, to give advice when new dresses and blouses are being purchased.

A sewing-maid should be handy and clever in contriving and renovating. By this means she will save her mistress much expense by enabling her to use up garments that might otherwise have to be discarded. By turning and patching, and by skilful adaptation, the best is made of every article of clothing. In a large family of girls the dressmaker's bill can be surprisingly curtailed by the ingenuity of a clever sewing-maid. She should study fashion books and papers, and try to keep her ideas up to date.

All her work should be neat and painstaking; she will, no doubt, find that the ladies for whom she works will themselves take an interest in her sewing. She will then let them help the work as much as possible, and if at first this means a little delay, it is worth the extra trouble. They will soon get into the way of such work and give much valuable help.

The sewing-maid's chief difficulty will be fitting; but if she has been taught her work well, she will be able to adapt her knowledge to the task in hand, and to obtain really satisfactory results. Unless asked to do so, the sewing-maid should refrain from giving advice on matters of dress, but when asked her ideas, she should state them fearlessly, and with a genuine wish to help her mistress.

THE NURSE

The position of head-nurse is one of great importance. She is responsible for the general arrangement of the nurseries, which are entirely under her care; she should, therefore, be a thoroughly sensible and trustworthy woman, who realises how much the character and development of her little charges depend on her efforts. The youngest child in the nursery will be her special charge. After the departure of the monthly nurse she will undertake the care of the infant, washing and dressing it, taking it into the open air and watching over its sleeping hours. She should, from the very first, endeavour to inculcate good habits in the child; these are easily formed by quite a tiny baby, and the lessons learned are seldom forgotten in later development.

Characteristics of a Good Nurse. A good nurse should have unlimited patience and sweet temper. Irritable manners and harshness should find no place in the nursery; they tend to make the children cross, and even untruthful. In the daily training of the children the nurse should watch for the earliest indication of individual characteristics. By her own influence she should make them feel the charm of unselfishness, gentleness, and perseverance.

In her personal appearance and habits the nurse should be invariably neat and clean. Her work is light and never menial, so she will have no excuse for dirty aprons and soiled hands. Of course the nursery routine will, to a certain extent, disarrange her dress, but she should endeavour to make herself tidy again as soon as possible.

A good nurse will always insist on implicit obedience, even from the tiniest child; but she will be very careful in telling the child what is to be done, and will never allow herself to become tyrannical.

Good order should reign in the nursery. Little children dislike confusion and misrule, and are made thoroughly uncomfortable by it. Good discipline does not necessarily mean severity, and the utmost gentleness and kindness are compatible with orderliness and obedience.

The nurse generally takes her meals in the nursery with the children, if she works single-handed, or afterwards if there are nursemaids working under her. Sometimes she may take her meals in the housekeeper's room, if she can leave her young charges in safe hands. The nurse should be clever with her needle, for she will have many hours which can be profitably spent sewing for her mistress or for the small inhabitants of the nursery.

THE UNDER-NURSE

One or more under-nurses will be kept, according to the number of children, and according also to the establishment. The under-nurse will clean the nurseries, scrub the floors, sweep, dust, and light the fires; and in every way she should endeavour to keep the nurseries neat and cheerful. She will carry up the nursery meals and clear them away; and under the supervision of the head-nurse she will be responsible for the dressing of the older children. Her spare time will be spent with her needle.

THE SINGLE NURSE

In a small establishment, where only one nurse is kept, her whole time will be occupied with her little charges. She will probably be assisted in her work by her mistress, who will endeavour to relieve her of the children for a few hours every day, in order that she may get the necessary rest and recreation. In most cases the nurse's outdoor exercise is assured, for she has to take her little charges for walks, and at the same time her own health benefits by the time spent in the open air. It is also important that the nurse should be allowed time to associate with her fellow servants. The greater part of the day will be spent with little children, who may be very sweet and lovable, but at the same time may be hardly old enough to be really companionable. Thus it becomes necessary for the nurse's own comfort that she should be given time to talk with the other maidservants, and become friendly with them.

Assistance with Nursery Work. The single-handed nursemaid will probably need some assistance with the rougher parts of the nursery work. Either the general servant or the housemaid will help to keep the nurseries clean, scrubbing the floors, laying the fires, and bringing the meals up from the kitchen. The exact organisation of the work should rest with the mistress, and she should do all in her power to let each maid know quite definitely what work she is expected to do. In this way little difficulties which might arise are smoothed over, and each servant can perform her work satisfactorily.

Nursery Meals and Medicine. The times of the nursery meals should be arranged by the mistress, and the food prepared should be ordered by her. The nurse should not allow constant eating and drinking between meals, and should discourage excessive sweet-eating.

In the matter of health, the nurse should be on the alert to detect symptoms of disease of any kind. She should at once inform her mistress of any important sign, and should never presume to dose the children herself, but act only under the doctor's orders.

THE CHARWOMAN

The duties of charwomen vary more widely, perhaps, than those of any other servant. Many charwomen merely act as cleaners, and work for a fixed weekly wage for a certain number of hours every day. Their duties in this case consist of sweeping, cleaning, and dusting rooms, scrubbing floors, and lighting fires in cold weather. Such women always provide their own food, and in many cases one woman may take the responsibility for several sets of offices.

The duties of the charwoman who goes to work in a private family also differ widely. In the generality of cases her work will supplement that of the ordinary domestic servant. Many mistresses arrange for a woman to come in once or twice a week to help with any special cleaning that has to be done. She will be called in to do the roughest household work, such as beating mats, and all kinds of rough cleaning

The actual wages earned by the charwoman will entirely depend on the locality in which she works. She is generally paid by the hour or day, at the rate, in a town, of about 2s. to 2s. 6d. the day. The hours at which the charwoman is expected to arrive and depart should be clearly stated at the time she is engaged.

Desirable Characteristics. The most efficient charwoman is the middle-aged married woman who was a domestic servant before her marriage. She will then be experienced in domestic matters and the routine of a house, and be more capable of doing useful work. The charwoman's temptations are many, so her honesty should be unimpeachable. She should be punctual, neat in appearance, clean in the execution of her duties, and very thorough and painstaking

THE DAILY SERVANT

In towns, where rents are high, and the expense of an extra bed-room are matters for careful consideration, many people find it desirable to engage a "daily" servant. In a small family living in a flat a daily servant is commonly engaged, the limited space in the flat making this arrangement more convenient.

The duties of the daily servant will, in this case, be those of a "general," except that, as the flat is generally small and the rooms fewer in number than in an ordinary house, her duties will be less arduous

Her wages will be correspondingly higher than those of a servant living in, for though her board is provided, she has to make her own arrangements for lodging. It is impossible to state any fixed wage, since the rate of payment varies so widely; but the average wage is from 7s to 10s per week.

BARBERS

In these days there seem to be objections to the use of the good old word barber. It is difficult to know why. For both etymological and historical reasons it is a good expressive word. Shakespeare uses it, and the Company of Barber-surgeons claims incorporation from the year 1461, although about a century later barbers were relieved of the duties of drawing teeth and letting blood, and restricted to the humble sphere to which they confine their craft to-day. The plea for calling a spade a spade urges that a man who operates on the beard should be designated a barber. Having made this protest, we kowtow to public and trade prejudice, and refer readers who would know something of the commercial side of barbering to the more genteel title "Hairdressers," later in this course.

BERLIN WOOL SHOPS

The name "Berlin wool shop," although still in general use, is somewhat of a misnomer nowadays, inasmuch as Berlin wool forms an insignificant feature in the equipment of a modern fancy-work or art needlework store. The stock-in-trade of such an establishment would include, in addition to all kinds of knitting and crochet wools and yarns, white goods, traced art linens and drawn-work, materials for ribbon-work, Russian cross-stitch, stencil-work, canvas-work, embroidery silks, yarns, "Lustrine," and filoselle, together with crochet cottons, transfers, lace-making requisites of various kinds, and the knitting and crocheting needles, tambour frames, wool-winders, etc., that are used by home-knitters.

Competition and Opportunity. Owing chiefly to the competition of the large drapery houses, each of which has its fancy-work department, the number of shops exclusively devoted to the sale of these goods is decreasing, so that this branch of shopkeeping would not at first appear to commend itself as a desirable speculation. Experience teaches, however, that shops of this kind, when managed by women who are themselves clever needlewomen and are competent to advise their customers, not only as to choice of designs or colours, but to show them the best methods of making up the materials sold and, if necessary, to commence the work, are in many ways superior to the large shops, where the assistants are frequently taken from other departments, and often have no practical knowledge as to the actual manipulation of the goods sold. Many customers prefer to deal with these special shops, and it will be a matter of regret if women allow to pass from their hands what is to many a congenial occupation as well as a means of livelihood. Moreover, it is a business in which very good profits are made.

Qualifications for Success. It must not, of course, be assumed that because a woman may be a skilful worker that therefore her success in business will be assured. The essential qualifications when opening a Berlin wool shop are a knowledge of bookkeeping and some experience of business methods, a capital of not less than £200, and a practical acquaintance with the work. To be a really efficient saleswoman it is desirable that the owner of the shop should serve an apprenticeship. But if this is not possible she should be assisted by someone who has been so trained; probably a daughter or younger sister would be chosen. Apprenticeship lasts from two to three years. As a rule no wages are paid during this period, and sometimes a premium is required. At the termination of her apprenticeship a girl can always find employment in the art needlework departments of the large stores, as there is an insufficient number of trained assistants to fill these vacancies.

The Start. A small shop in a populous neighbourhood should be selected, and the fittings would (like those in a baby-linen shop) consist merely of plain wood shelving, a glass case or two—a counter with glass top for preference—and in the shop and in the window several brackets, on which to display the goods. Although Berlin wools originally came from Berlin, and many still do so, the bulk of the wool sold is of English or Scotch manufacture. There are large woollen warehouses, or agencies, in London, Manchester, and various Midland centres for Berlin wools, merinos, and so forth, and Alloa and Greenock, in Scotland, are noted for their wools; while Welsh yarn is preferred by others. The beginner would lay in for an opening order, probably a dozen shades in Berlin wools (reds, blues, greys, etc.), but only in 1 lb. quantities. Scotch yarns are popular, and full of diversity in colours. The "heather mixtures" are innumerable, but a judicious selection of about 20 lb. of Scotch yarns would suffice; 6 lb. of Andalusian wool, and the same quantity of Shetland, should be enough, but it must be remembered that black and white should be secured in each case, and the colours made subsidiary and as select as possible, until the needs of the neighbourhood are determined. Then there is the "Lady Betty," a soft wool of varied thicknesses (two, three or four-ply), for making vests and other underwear;

2 lb. of each thickness would be wanted, and 6 lb. or so of fleecy wools (in white and plain colours). Of fancy wools (which are sold by the ball), one dozen balls would be needed of rabbit wools, and the same quantity of ice wools. These are not in plain thread like the others, but make up, in the case of ice wool, like astrachan, and with rabbit, like fur. Ostrich wool and Smyrna wool (for Oriental rugs) are likewise in favour. Then we come to knitting silks (speckled and plain), for dainty socks or for edging. These are in fast dyes of all colours, and Pearsall's silks are world-known. Of these, about 6 lb. would be required, in 1 oz. balls, four balls being required for a pair of gentleman's socks. Then there are embroidery silks of various kinds—twisted filoselle, filo floss, twisted flannel, and purse silks. These are sold in different colours and sets of shades. The purse silks are the most expensive, and filoselle and filo floss are used principally for embroidering chasubles, stoles, altar-cloths, and ecclesiastical vestments. The embroidery silks are sold in packets, and a careful selection of various colours is necessary. The same applies to embroidery cottons (white and ingrain)—which are sold in skeins—and to flourishing thread. An expenditure of £5 would give one a very fair selection of embroidery needles, knitting pins (bone, wood, vulcanite, and steel), crochet needles, rug needles, netting needles, and meshes (in wood and bone). In this category we might also place tambour frames, square frames (for working on), and wool-winders.

The Accessories. Besides the actual materials mentioned there ought to be a stock of articles for embroidery in silk or cotton, and either coloured or white. Among such are table-centres, duchess sets, nightdress cases, comb-bags, linen bags, antimacassars, tray-cloths, doyleys, and hem-stitched and drawn work. Also squares for cushions must not be forgotten. The same thing is obtainable in art serge, Roman satin (for sofa rugs, portières, etc.), pure satin, silk, or other fancy materials. These are usually bought ready-made, with fancy patterns on them. A few pairs of traced slippers, some canvas to be worked in wool, and tobacco-pouches, braces, shaving-cases, are all used for embroidery.

Then there are numbers of made-up goods, such as sofa-cushions, tea-cosies, egg-cosies, pincushions, and tidies, handkerchief and glove sachets (hand-painted on satin many of them), which might be stocked. A small stock should be laid in of such things as cushions covered with cretonne, pincushions, and other fancy articles for ladies' own mounting. Many linen articles are sold with the work started (sprays, flowers, monograms, etc.), to indicate how to proceed. It would likewise be well to include a supply of transfer patterns. These are used for ironing designs on linen or silk; nothing with a pile upon it like velvet can be transferred in this way. Books of designs are to be obtained. Of late years Teneriffe work has become very popular.

Credits and Prices. The same conditions regarding opening orders hold good in the Berlin wool trade as in drapery and its allied branches. A sure capital (though small) and good credentials will ensure ready acceptance of orders by any of the large wholesale houses, and much salutary advice regarding opening selections will be obtained from the accredited experts of the trade. The draper, of course, is cutting largely into the trade, and new openings, with a chance of full prices, are not frequent in large centres, and particularly in the metropolis. But even the large drapery houses look on the art needlework department as one of their best paying sections, and the average rate of profit is put at from 30 to 40 per cent. on wholesale prices. The selection of stock and the rate of profit charged would, as in all businesses, depend upon the neighbourhood. In some localities, for example, lace-making is the popular form of work, and in such cases materials for lace-making would be stocked in greater proportion, and prices would be proportionately less or greater, according to the amount of competition.

Methods of Cultivating Business. With a view to forming a connection, attractively drawn up circulars should be sent out in the neighbourhood, particularly to the mistresses of girls' schools and kindergartens, and to the members of church needlework guilds or Dorcas societies. The circulars should call attention to the fact that customers may receive instruction in the work if desired. If it be possible to form classes for teaching embroidery or any form of lace-making, etc., it will be found profitable to charge rather low fees for the tuition, as the primary object of such classes is to sell the materials used. Within the last few years the revival of embroidery as a trimming for ladies' dresses and blouses, and the great popularity of coarse crochet lace, especially Irish crochet, have created a fresh interest in both branches of industry, which at present are proving a profitable form of home employment to many.

In some country towns the owners of Berlin wool shops also keep a registry office for servants. This proves useful in bringing a number of people to the shop, which should be very tastefully arranged, with the novelties prominently displayed. The windows should be attractively dressed but not overcrowded. The saleswoman should keep herself well informed as to new fashions and fancies, particulars of which will be found in the art needlework journals, which should also be stocked and sold.

BOOKSELLERS

There are some trades which, though by no means extremely profitable to those who engage in them, have at least the advantage of being pleasant to pursue, and of these we may say that none is pleasanter than bookselling.

We have met booksellers who had better have taken to butchering or innkeeping, so ignorant and indifferent were they to the interesting features of their work, having, for instance, never heard of some well-known authors. We also know a librarian in charge of a great library, in a provincial city of half a million inhabitants, who was under the impression that Mr. Robert Barr was the author of "The Little Minister" and "A Window in Thrums." These are the round pegs in square holes, mentioned in the article on "The Choice of a Career," in the first part of the SELF-EDUCATOR, and we must not stay to consider them, but need only urge that no man who is not naturally fond of handling—not necessarily reading—books, and who is not interested in the names of authors and the works they have written, should contemplate for one moment the business of bookselling with any hope of succeeding therein.

The Bookseller's Assistant. As the beginning of every successful man is in some humble position in the trade in which he has made up his mind to excel, we begin with the bookseller's assistant rather than by describing how to start a bookselling business. Given the taste for books, a good memory, a bright address, hardly anyone who desires to become a bookseller need fail of the opportunity. There is no formal apprenticeship nowadays, and the conditions of employment will vary in every town, if not with every employer. In London, a youth will be taken on at 10s. or 12s. a week to learn the business, and in the course of five or six years—but largely according to the ability he displays—he will be accounted a fully-qualified assistant, his salary varying from 30s. to £2 a week. A chief assistant, where the proprietor is manager, will seldom get more than £3 a week, and £4 would be thought a good wage for one in charge of a considerable bookselling business. In the provinces a lower scale of wages is the rule: but, as living expenses are much less than in London, the remuneration is proportionately as good.

His Duties. The duties of the young assistant are at first limited chiefly to opening the parcels of books received from the wholesale houses, checking the invoices, and placing the books on the shelves or in the stock-room, according to his instructions. In London he will often have to go to the wholesale houses, or perhaps to the publishers, for books which have been specially ordered by customers. In the provinces there are also many large firms that confine their energies to the distribution of books and periodicals, though a good deal of correspondence is necessary in the case of provincial booksellers, as it is not always possible to secure an uncommon book from a local wholesale house, and it must then be ordered from London. The assistant who has an aptitude for lettering will be most useful to his employer, and we would advise young men, seriously aiming at success by making themselves of the greatest possible use to their employers, to go to the trouble of taking some lessons in designing, so that they may be able to write neat tickets for placing on the books in the windows. The bookseller who is alive to his business knows how much good may come from neat little cards with some special wording on them; not the same as every other bookseller may be showing, but something much more personal. We need not detail the other duties of the young assistant, which can be easily discharged by any youth of average intelligence; but of vital importance is the cultivation of the memory.

Use of the Memory. A bookseller's assistant who has a defective memory is a nuisance to everybody concerned, and ought to leave a business in which he can never hope to succeed. Why? Because, when a customer comes in and asks, let us say, for an edition of Chaucer without knowing quite which edition he wants, the assistant who can immediately tell him there is an edition at 3s. 6d., by the Oxford Press; the great edition by Professor Skeat, in six volumes at £4 16s.; and three volumes in the World's Classics, at 1s., and so on—the assistant who knows this is distinctly up to his business, and the one who does not know it without wasting the customer's time turning up catalogues, and fluttering about asking questions, is an incompetent. A course of memory training should be undergone by every ambitious assistant who is not naturally gifted with a "head for titles." We know men who seldom read books, and are in no sense to be regarded as persons of literary taste, yet there is hardly a book published within the last twenty-five years which they cannot tell you about – title, author, publisher, price, all are registered in their memories, and you have but to ask to be correctly informed. These are the ideal booksellers. The public don't want literary *opinions* from a bookseller—they want *information*.

Opinions and Knowledge. The latter quality the assistant can acquire by carefully and regularly following the trade papers, such as the "Publishers' Circular" or "The Athenæum," noting the names of all new books, and judging by the reviews whether they are likely to be in demand, and by what class of readers It is quite in order for an assistant to remark to a customer, "I notice this book is favourably reviewed in 'The Times,' it is greatly in demand"; but for him to say, "I have read this book and think it admirable," is generally an impertinence. The average assistant is not qualified to pass opinions on the books he sells, and nothing is more irritating to a person of cultured literary taste than to have some forward youth giving his ill-digested opinions on a work of literature. His business is to know where the book is, to get it instantly; or, if it is not in stock, to say how soon it can be supplied; to know the exact price, and not to be familiar in his conversation, but deferential.

The Bookseller. It is, of course, not easy to draw the line between the duties and qualifications of the assistant and those of the bookseller himself, as these merge into each other, and are entirely conditioned by the peculiar circumstances of each case. But we can best be of service by supposing that one who has been an assistant for a number of years contemplates starting for himself How will he go about it?

First he must know the terms on which books are obtained. Books are sent out from publishing houses at 33⅓ per cent. less than the published price, but the bookseller has always to pay *carriage*, and to those in the provinces this is a heavy item. Thus, a 6s. novel, which sells retail at 4s. 6d., is bought by the bookseller at 4s. 2d., thirteen being given as twelve. Different publishers have different tariffs, but this we may take as an average. So that, if a bookseller can dispose of thirteen copies of a new 6s. novel, he makes a profit of 8s. 6d., less the cost of carriage in the case of a country business, and the necessary shop expenses. There is a class of book which is far more profitable—"reprint" and juvenile literature. Such books are usually sold to the trade at half price, thirteen copies of a 1s. book, or an "assorted" 13 12, costing the retailer 6s., and realising 9s. 9d., which is better business than novel-selling, and involves less risk. Consequently, many booksellers look upon this class of book as their "bread-and-butter"; being always in demand, they can stock sufficient quantities to secure the full trade discount, and be assured that, sooner or later, they will dispose of the stock, whereas novels are always a lottery, and sometimes involve the venturesome bookseller in serious loss. It often happens that some novelist makes a great hit with a book, and the booksellers are tempted when that writer's next work is being "subscribed" to order a good quantity. It falls flat, and the booksellers are left with unsaleable stuff, for which they have had to pay. Therefore, unceasing care has to be taken not to "plunge," and not to anticipate so much as to follow close upon public taste. Net books are perhaps the most satisfactory of all to handle, and yield a profit of 7½ per cent. to the retailer. In this class are included all sorts of technical works, which are published at all sorts of prices. A 15s. educational work will thus yield the retailer 1s. 1½d., a good deal less in proportion than a "half-price" book; but works of this kind are usually obtained to order, do not need to be stocked, and involve no trouble or risk whatever to the dealer.

Dealing with the Wholesalers. A bookseller may either buy directly from the publishers or from the wholesale houses. The great majority of the retailers deal with the large distributing agencies, for only those who can order large quantities of books can afford to trade direct with the publishers, who supply their own list of books only. The large distributing firms in London and the leading provincial centres have vast numbers of booksellers who run accounts and get all their books from them, and these firms employ travellers who call upon their customers to show copies of the more important forthcoming publications. There is no book or magazine too small for these great firms to supply, and the constant complaints which reach publishers from readers unable to secure copies of their books or magazines are proof that many booksellers simply do not know their business, or will not be at pains to secure for their customers the books or papers they most desire. In passing, we may remark that the young man who can get into one of these large wholesale houses for a time in any subordinate capacity will learn much that will be of value to him in the retail trade.

Opening a Shop. We now come to the question of opening a shop. Nothing definite can be stated as to the amount of capital required. One man with experience and knowledge will make a better start with £100 than another lacking these qualifications will do with £500. All depends upon the man and the local conditions. There are so many varieties of bookselling that we cannot describe them all. But we will take three of them.

1. There is, first, the pure bookseller, who, selecting some high-class locality—perhaps in the neighbourhood of one or two schools attended by the children of the better classes—determines to sell books only, and to stock the best class of literature and educational works.

2. Another type is the bookseller who combines books of a good class with cheaper literature; standard libraries, like the "World's Classics"; part publications, like the "Harmsworth Encyclopædia"; and monthly magazines, together with picture postcards, fancy goods, and stationery.

3. The bookseller, newsagent, and tobacconist, who deals almost entirely in "half-price" books of the "bread-and-butter" variety, and in all sorts of periodicals, as well as tobaccos, is a large factor in the trade.

Three Kinds of Businesses. Obviously, the first of these requires the largest capital, as his rent will be greatly in excess of the others', the value of his stock much higher, his accounts longer outstanding, and his whole "style" much more expensive to maintain. In the end his profits are often not greater, and are sometimes less, than those of the other classes; but his position in society is superior—he is less of a tradesman and more of a professional. It is clear, therefore, that unless one has sufficient capital to wait for a year or two before seeing any very substantial results, the first class of business is not one to be lightly entered upon.

The bookseller and fancy goods dealer represents a line of business in which the returns are likely to be quicker and where a smaller capital will enable a man with industry and business acumen to build up a profitable trade in a much shorter time. [See FANCY GOODS AND STATIONERY.] A valuable adjunct to this class of business is to secure an appointment as a branch postmaster, which, while it does not mean a great deal in the way of actual income, for the money paid is usually less by a good way than the services rendered, has indirectly an important effect on the business by bringing a large number of possible customers into the shop. [See POST OFFICE.] In the case of the better-class trade, however, this is a thing to be avoided, because the postmaster must admit all sorts and conditions of people into his shop, and this constitutes a drawback to the high-class trade. The locality must be as carefully chosen for the second class of business as for the first.

A suburban district is most suitable, and the class of literature will be largely conditioned by the local tastes. As a rule, it is not of the highest nor yet is it of the cheapest. A lending library, in which books are lent out at twopence per week, can be run with profit in connection with such a business. Numerous secondhand dealers in London will secure current novels for use in such libraries at considerably less than the trade price soon after they have been published.

The "bookseller, newsagent, and tobacconist" [see under these respective trades] implies a lower middle-class, or working-class locality. It means very long hours, as one must be astir early in the morning to see that the papers are distributed to the errand-lads who take them around to the houses, and the shop must be kept open later than an ordinary bookseller's. The books sold are the very cheapest, limited almost entirely to reprints of standard authors, at 1s. or 1s. 6d., together with juvenile literature, from the 3d. toy-book to the 5s. story by Henty Manville Fenn, and others. The stationery would also be of the cheapest kind.

The whole secret of success in any of the three grades of booksellers we have indicated is to choose carefully one's location, and, having chosen that, to cater as carefully for the tastes of the locality.

The Bookseller at Work. Of course, the clerical side of the business is very much the same as any other, as far as bookkeeping and accounts are concerned, so we shall not enlarge upon it, nor upon the need for accurate monthly statements, where dealing with regular customers; but by far the greater part of the business will be cash, and each one will evolve for himself the system that best suits his requirements. The most important matter is the purchasing of stock. The bookseller must beware of the traveller for the wholesale firm until he has proved him a reliable judge of the literary market, remembering that it is his business to get the bookseller to subscribe for as many copies as possible of the forthcoming book which is going to have a bigger "boom" than any book that has ever appeared before. But really no advice can be given as to purchasing stock; nothing but experience will tell a man what sells in his neighbourhood. He must be guided very largely by the demand at the counter. That is his criterion rather than the opinions of the literary papers, or the enthusiasm of the publisher's traveller.

Studying the Seasons. Of the utmost importance is a shrewd observance of the various seasons; showing and stocking just the kinds of literature for the changing year. Christmas literature is so obvious that it need not be mentioned, but far more might be done by booksellers with maps and guide-books if these were judiciously bought and displayed at the beginning of the spring season. And good results from grouping books of the same character together at such seasons, taking, let us say, 20 or 30, or double that number, of light novels for window display, under the general heading of "Reading for Summer Days," in June, July, or August. If there are schools in the neighbourhood, especially, and often if there are not—for there will be scholars always—some show of educational books, chosen with due regard to the character of the local inhabitants, should be made about the beginning of September.

Publicity. Advertising is as important to the local bookseller as to the great publishing firm. Every publishing house is only too delighted to supply, on application, advertising matter, say, for a new book, a new magazine, a series of books, and the bookseller is wise who distributes these circulars, often prepared at great cost, bearing his own name and address impressed by a rubber stamp, or even printed, if he happens to have a small printing press. Such a press, by the way, is a very good thing for the enterprising bookseller of the second class to possess, as it soon pays for itself and earns a good profit, the wages of a jobbing compositor and a cropper-boy not being at all difficult to meet with the amount of printing noteheads, invoices, visiting cards, etc., which can thus be done "with neatness and dispatch." It costs wonderfully little to keep one's name before the local public if all the facilities are taken advantage of, and the bookseller who does not advertise, by sending circulars round the neighbourhood, continually changing his window and devising new and attractive tickets for the books he is showing, cannot hope to prosper in these days of extreme competition.

Some of the larger booksellers issue elaborate and costly catalogues in which they give specimen illustrations—supplied by the publishers—and admirably arranged lists of new and recent books, most of which they have in stock or can get in an hour or two. This, of course, is the princely way of doing the thing, but it means increase of business. Others, again, have taken to advertising their names in the local papers as having in stock, and willing to send to any address, a given list of the latest books in fiction, science, and so forth. Both of these methods are, of course, beyond the beginner, and presuppose considerable capital and an already established business.

Studying Customers. With booksellers of the first class, especially, there is great need for studying the individual tastes of every regular customer. We know, for instance, of several large booksellers who are so familiar with the tastes of many of their customers that they can tell to a certainty which new books are likely to interest them, and will fearlessly buy these books with the knowledge that these customers will take them. Indeed, in many cases such clever booksellers secure the books and send them out to likely customers on approval, and the amount of good business that may be done in this way is really wonderful. But it requires a man of very shrewd judgment to work on these lines.

While we have deprecated the presumptuous assistant urging his views of literature upon customers who, in all likelihood, are much better informed than himself, we must point out the need to be alert in placing new books before every likely buyer, cultivating the habit of pleasing conversation, and freely showing any work of unusual interest to the customer who seems interested in inspecting the stock.

"Special Lines." Then, of course, in bookselling, as in every other trade, it is well at times to get up some special line which attracts buyers. Annual sales, in which books that have not gone off so well as was anticipated are marked down at a low figure, may, by attracting increase of customers, do something to redeem a loss, and it is always well to make a show of a local author, or a book of local interest, and to push it "for all it is worth"; though not to emulate a Nottingham bookseller, who bought such a stock of a novel by a local writer that in a few weeks he was glad to ticket the book at 6d. per copy less than he had paid for it. A volume by a local minister whose sermons have been published by some good publishing house—but never, oh, never! one who has had his dull discourses printed at his own expense by some tenth-rate firm—is a good line on which to specialise for a while.

Another thing that every enterprising bookseller should do is to arrange with some firm to print a book of good local views which will sell at a reasonable figure, and, by carrying his name as publisher, be an advertisement of his business wherever it goes. A local guide-book, carefully compiled, is also another sure selling production, quite within the scope of any bookseller.

Other Adjuncts. In addition to the several adjuncts to the bookseller's business already mentioned, there are others equally worthy of consideration, which we may briefly mention. Orders will, of course, be taken for bookbinding, but in this matter the bookseller can only act as an agent until he has formed a very considerable business, which would enable him to engage a skilled binder, and do the work himself. Print selling and picture framing form a natural combination with bookselling, and both are fully described in another part of the SELF-EDUCATOR. Then, where space is not so expensive as it is in the heart of the great towns, but where the position is still sufficiently central, a reading and writing room is a good thing to provide as an attraction to customers who are members of the lending library connected with the shop. It very soon pays for itself; and even afternoon teas might be provided at a cost which will make them profitable. A servants' registry is another useful and remunerative agency that may be started. And, in a word, the struggling bookseller must not rest content until he has tried every possible adjunct which can reasonably be associated with his business; for it is all too true that bookselling alone, unless in very special cases, is by no means a very remunerative business nowadays.

Secondhand Bookselling. In some ways the secondhand trade is more attractive than the new. It requires of its followers a thorough love of books for their own sake; a specialised knowledge of the value of old books whose published prices do not always bear any ratio to the prices they may fetch from people who want them, and quick decision in estimating the worth of a bundle of old books put up at auction, a secondhand dealer having to attend numerous sales in search of his stock, though a great deal can also be had by private treaty. Withal, the margin of profit is far better than it is in the new trade, and there is no danger of anything losing value by becoming shop-soiled. It is in the secondhand trade that we look for a man of real literary knowledge, and, although we meet many who are utterly incompetent, the fact that such can make a living indicates that the man who does know books and their value need not fear failure in it.

About Catalogues. Cheap postage has been a great boon to the secondhand dealer, and enables a man of moderate enterprise and moderate capital to push his business wonderfully. He is wise if he specialises in some particular branch of literature while still handling all sorts of books. He might make medical books his special line, or Oriental books, or biography, or sport, travel, poetry, or "first editions." A most important feature of the secondhand trade is cataloguing. If possible, monthly catalogues should be sent out, certainly every second month a revised catalogue should be forthcoming. There is nothing of a special nature to say about a catalogue, as one is like another, and so long as it is properly arranged in alphabetical order, with the names of the books clearly stated, prices and dates given, no more can be done. Some slovenly dealers send out catalogues which are a mere mess of wrongly-spelt and unclassified titles, usually produced in a slum printing house, a thing that makes one afraid of getting disease from touching it. It pays to print a catalogue well. "Who's Who," "The Literary Year Book," and other works of reference, contain any number of addresses to which it is advisable to post each new catalogue, and the volume of business which can thus be done through the post from an address in some suburb, or, indeed, from any part of the country, is surprising. The youth who has the love of books in him need have no difficulty in finding an opening with some secondhand dealer.

The "Back-Number" Business. We need only add, in conclusion, that for one who has some little capital which he can lay out for a few years, and is in no immediate necessity of a return for his money, there is a good opening in the "back number" trade. The idea is to buy old numbers of all the best magazines and part periodicals, have them properly examined to find if they are perfect, and then store away in order of their dates. There is a constant demand for such back numbers to complete sets, and the dealer can afford to sell them at half-price and make a handsome profit, as a sack-load of back numbers will cost him but a shilling or two, and may contain scores of magazines which in a few years will sell out at thirty or forty times what he paid for them, his profit being justified by his waiting and the cost of the space he must devote to a large stock, for a large stock is essential to success.

Continued from page 1040

By Sir ISAAC PITMAN AND SONS

IN addition to the methods of representing vowels and diphthongs shown in the second instalment of this course, there are other devices for vocalization employed in the Pitmanic system to which the student is now introduced. By mastering these instructions he will complete his knowledge of the methods used for the accurate representation of all possible combinations of vowel sounds in the language.

Vocalization of *PL* and *PR*. The *pl* and *pr* series may sometimes be used to obtain a good outline, even though an accented vowel comes between the two consonants. In such a case the LONG dot vowels BETWEEN the two letters are expressed by a small circle BEFORE or ABOVE the consonant stroke; thus

chairman, careless, cashiered, souvenir.

The SHORT dot vowels are indicated by a small circle placed AFTER or UNDER the consonant; thus

dark, gnarl, German, girl.

In cases where it is inconvenient to observe this rule, the circle may be written on EITHER side, for either a LONG or a SHORT vowel; thus

regard, engineer.

A stroke vowel or diphthong is struck THROUGH the consonant; thus

school, record, tincture.

Single stroke words vocalized in the above ways are halved for either *t* or *d;* thus

court, cold.

When an initial hook or circle would interfere with a first-place vowel or diphthong, or a final hook or circle with a third-place vowel, the vowel-sign may be written at the BEGINNING or END of the consonant; as

child, dormouse, corporation,

figuration, figures.

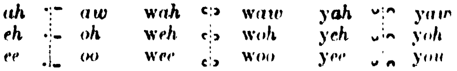
It is seldom necessary to vocalize the *pl* and *pr* series to mark an unaccented vowel; thus

permit, vocal;

but accented vowels may be inserted; thus

pervert, pervert.

***W* and *Y* Diphthongs.** When *w* or *y* is followed by any simple vowel, a diphthong is formed, which is represented by a semicircle written in the same position as the simple vowel; thus



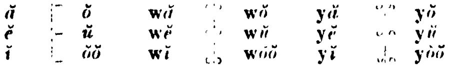
ah	*aw*	*wah*	*waw*	*yah*	*yaw*
eh	*oh*	*weh*	*woh*	*yeh*	*yoh*
ee	*oo*	*wee*	*woo*	*yee*	*you*

The following are examples of the use of the above signs:

zouave, railway, seaweed, chamois, misquote,

Indiana, associate, yearly, folio, youth.

The same signs written LIGHT represent diphthongs formed of *w* and *y* and the SHORT vowels; thus



ă	*ŏ*	wă	wŏ	yă	yŏ
ĕ	*ŭ*	wĕ	wŭ	yĕ	yŭ
ĭ	*ŏŏ*	wĭ	wŏŏ	yĭ	yŏŏ

The following are examples of the use of the above signs:

thwack, twenty, twinge, memoir, password,

lamb's-wool, serial, alien, atheist,

patriot, piteous.

It is in practice rarely necessary to make any distinction between light and heavy signs. It will be seen that the SIDES of the circle ( ) represent the *w* diphthong, while the lower and upper halves ◡ ◠ represent the *y* diphthongs.

The right semicircle ʾ representing *waw* or *wŏ* may be prefixed to a stroke consonant where it is convenient; thus

walk, water, watcher, washer, war, warp.

The left semicircle ʿ is prefixed to downward *l*, and the right semicircle ʾ is prefixed to *k, g, m, mp,* to represent *w* only; thus

William, Wilson, wake, wig, woman, wampu

This sign is always read *first*, so that when a vowel precedes *w* the stroke must be written, and not the abbreviation, thus

awake, *wake*.

Initial *AW*. At the beginning of a word, the vowel *aw* may be joined to upward *l*, as

awl, *alter*, *alteration*;

and the logogram *aw* (all) may be joined in compound words beginning with *all-* or *al-*; thus

Almighty, *already*, *almost*, *all-wise*.

Disyllabic Diphthongs. In addition to the signs already given for diphthongs, most of which are monosyllabic (or one syllable), the following series of angular characters is employed for the representation of disyllabic (or two syllable) diphthongs.

ah-i, *eh-i*, *ee-i*, *aw-i*, *oh-i*, *oo-i*,

as in

sol-fa'ist, *la'ity*, *howbe'it*, *flaw'y*, *sto'ic*, *bru'in*.

Those signs are written in the same places as the long vowels, and may be used to express a long vowel followed by ANY *unaccented* short vowel which may occur; thus represents the diphthong in *clay'ey* or in *bay'onet*; that in *re'al*, *re'instate*, or *muse'um*; that in *draw'er* or *flaw'y*; that in *Noa'h*, *Noe'l*, or *o'olite*; that in *jew'el* or *Jew'ish*.

Where a long vowel or diphthong is followed by an *accented* short vowel, separate vowel signs are written, or the *y* series is employed. Compare the following words:

poet, *poëtic*, *re-elect*, *re-éligible*, *reinforced*,

re-énter; *geological*, *geólogy*, *theatre*,

theátrical; *realty*, *reálity*; *pean*; *piáno*.

When two vowels occur in succession, not thus provided for, write the separate vowel signs; thus

Leo, *Louisa*, *Ohio*, *Messiah*, *Isaiah*, *royal*, *dewy*.

Frequently occurring beginnings and terminations of words are represented in shorthand by single signs, in accordance with the following rules.

Prefixes. The syllable *com-* or *con-* occurring at the beginning of a word is expressed by a light dot written before the first consonant; thus

commit, *community*.

When the syllable *cog-*, *com-*, *con-*, or *cum-* comes between two consonants, either in the same or in a preceding word, it is indicated by writing the syllable or word that follows UNDER or CLOSE TO the consonant or word that precedes; thus

recognise, *decompose*, con*fined*, incum*bent*.

Inter-, *intro-*, or *enter-* is generally expressed by *nt*; thus

inter*lock*, intro*spect*, enter*prise*.

The prefix may be joined when this course does not occasion ambiguity.

Magna, *magne-*, or *magni-* is expressed by a disjoined ; thus

magnan*imity*, magne*tized*, magni*fy*.

Self- is represented by a disjoined circle *s*; thus

self-*defence*.

In- before the circled letters is expressed by a small hook, written in the same direction as the circle; thus

in*spiration*, in*strument*, in*scribe*,

in*herent*, in*human*.

Except in the word *inhuman* (which cannot be mistaken for *human*) and its derivatives, the small hook for *in* is never used in negative words, that is, in words where *in-* would mean *not*. In all such cases *in-* must be written with the stroke , as

hospitable, *inhospitable*.

Suffixes. The suffix *-ing* is expressed by the stroke , and *-ings* by ; thus

facing, *facings*, *evening*, *robbing*.

When the stroke is not convenient, *-ing* is expressed by a light dot at the end of the word, and *-ings* by a light dash; thus

hoping, *plotting*, *plottings*, *turning*, *turnings*.

The suffixes *-ality*, *-ility*, *-arity*, etc., are expressed by disjoining the preceding stroke; thus

formality, *carnality*, *geniality*.

The sign is employed as a contraction for *-ment*, when following *n*, *ns*, or a hook, when it will join easily; thus

imprisonment, *commencement*.

The cuffix *-mental*, or *-mentally* is expressed by *mnt*; thus

instrumental or *instrumentality*.

Generally *-ly* is expressed by ; thus

poorly.

Where it is inconvenient to join the it may be disjoined; thus

friendly.

The circle *s* is used to express *-self* and the large circle to denote *-selves*; thus

thyself;

it is sometimes joined, as in

myself, *himself*, *themselves*.

To express *-ship* is used, as in

stewardship.

Sometimes the character may be joined; thus

A disjoined is used to express *-fulness*; thus

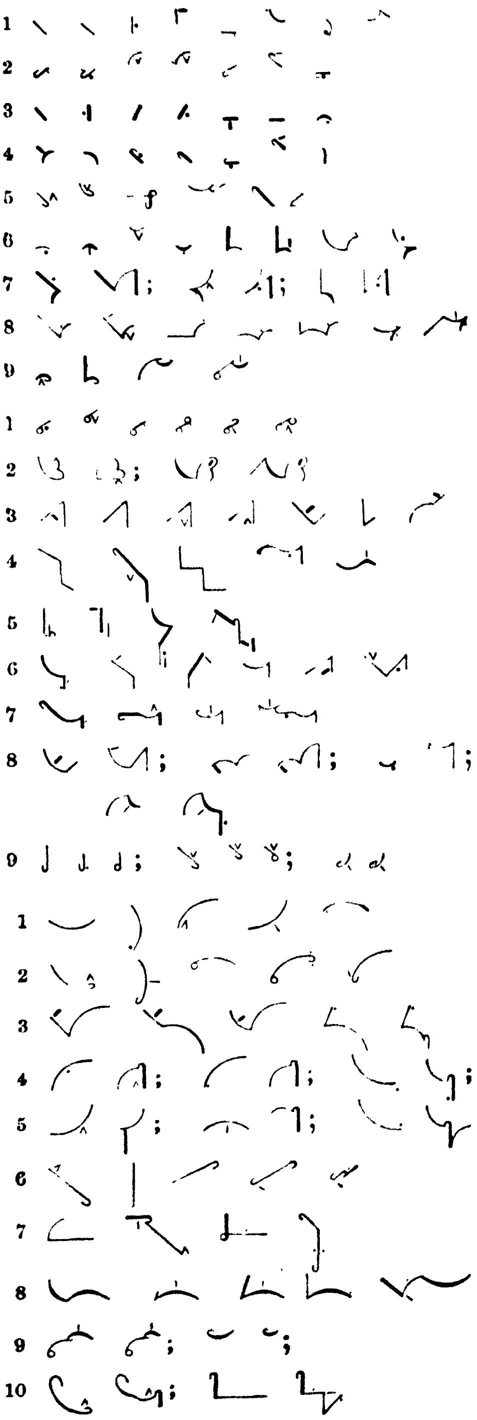
restfulness.

A disjoined is used for *-lessness*; thus

lawlessness.

Writing and Reading Practice. At this stage of his study, the student is advised to exercise his shorthand attainments by making use of suitable matter for writing and reading practice. He should obtain "Pitman's Shorthand Reading Lessons, No. 1" (price 6d.), which contains graduated reading printed in shorthand characters; he should also procure "Key to Pitman's Shorthand Reading Lessons, No. 1" (price 2d.), which is in ordinary print. Taking the "Key," he should translate the longhand words and sentences into shorthand, and afterwards revise and correct his work by the printed shorthand of the "Reading Lessons." He will also find it advantageous to utilize the Learner's and Corresponding Style portions of the shorthand pages given weekly in *Pitman's Journal* (price 1d.) in the same way.

KEY TO EXERCISES IN LAST LESSON.



Continued

This sign is always read *first*, so that when a vowel precedes *w* the stroke  must be written, and not the abbreviation, thus

awake, wake.

Initial *AW*. At the beginning of a word, the vowel *aw* may be joined to upward *l*, as

awl, alter, alteration;

and the logogram  *aw* (all) may be joined in compound words beginning with *all-* or *al-*; thus

Almighty, already, almost, all-wise.

Disyllabic Diphthongs. In addition to the signs already given for diphthongs, most of which are monosyllabic (or one syllable), the following series of angular characters is employed for the representation of disyllabic (or two syllable) diphthongs:

ah-i, eh-i, ee-i, aw-i, oh-i, oo-i,

as in 
sol-fa'ist, la'ity, howbe'it, flaw'y, sto'ic, bru'in.

These signs are written in the same places as the long vowels, and may be used to express a long vowel followed by ANY *unaccented* short vowel which may occur; thus represents the diphthong in *clay'ey* or in  *bay'onet;* that in *re'al,*  *re'instate,* or  *muse'um;* that in  *draw'er* or  *flaw'y;* that in *Noa'h,*  *Noe'l,* or *o'olite;* that in  *jew'el* or  *Jew'ish.*

Where a long vowel or diphthong is followed by an *accented* short vowel, separate vowel signs are written, or the *y* series is employed. Compare the following words:

poet, poétic, re-elect, re-éligible, reinforced,

re-énter; geological, geólogy, theatre,

theátrical; realty, reálity; pean; piáno.

When two vowels occur in succession, not thus provided for, write the separate vowel signs; thus

Leo, Louisa, Ohio, Messiah, Isaiah, royal, dewy.

Frequently occurring beginnings and terminations of words are represented in shorthand by single signs, in accordance with the following rules.

Prefixes. The syllable *com-* or *con-* occurring at the beginning of a word is expressed by a light dot written before the first consonant; thus

commit, community.

When the syllable *cog-*, *com-*, *con-*, or *cum-* comes between two consonants, either in the same or in a preceding word, it is indicated by writing the syllable or word that follows UNDER OR CLOSE TO the consonant or word that precedes; thus

recognise, decompose, confined, incumbent.

Inter-, *intro-*, or *enter-* is generally expressed by *nt*; thus

inter*lock*, intro*spect*, enter*prise*.

The prefix may be joined when this course does not occasion ambiguity.

Magna-, *magne-*, or *magni-* is expressed by a disjoined ; thus

magnan*imity*, magne*tized*, magni*fy*.

Self- is represented by a disjoined circle *s*; thus 
self-*defence*.

In- before the circled letters  , is expressed by a small hook, written in the same direction as the circle; thus

in*spiration*, in*strument*, in*scribe*,

in*herent*, in*human*.

Except in the word *inhuman* (which cannot be mistaken for *human*) and its derivatives, the small hook for *in* is never used in negative words, that is, in words where *in-* would mean *not*. In all such cases *in-* must be written with the stroke , as

hospitable, inhospitable.

Suffixes. The suffix *-ing* is expressed by the stroke , and *-ings* by ; thus

*fac*ing, *fac*ings, *even*ing, *robb*ing.

When the stroke is not convenient, *-ing* is expressed by a light dot at the end of the word, and *-ings* by a light dash; thus

*hop*ing, *plott*ing, *plott*ings, *turn*ing, *turn*ings.

The suffixes *-ality*, *-ility*, *-arity*, etc., are expressed by disjoining the preceding stroke; thus

formality, *carnality*, *geniality*.

The sign is employed as a contraction for *-ment*, when following *n*, *ns*, or a hook, when it will join easily; thus

imprisonment, *commencement*.

The suffix *-mental*, or *-mentally* is expressed by *mnt*; thus

instrumental or *instrumentality*.

Generally *-ly* is expressed by ; thus

 *poorly*.

Where it is inconvenient to join the it may be disjoined; thus

friendly.

The circle *s* is used to express *-self* and the large circle to denote *-selves*; thus

thyself;

it is sometimes joined, as in

myself, *himself*, *themselves*.

To express *-ship* is used, as in

stewardship.

Sometimes the character may be joined; thus

A disjoined  is used to express *-fulness*; thus

restfulness.

A disjoined is used for *-lessness*; thus

lawlessness.

ELECTRICITY

8

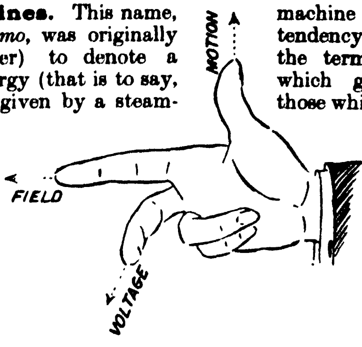
Continued from page 961

THE DYNAMO

Mechanical Generation of Currents. Field-magnets and Armatures. Commutator and Brushes. Armature Windings. Excitation of Magnetism

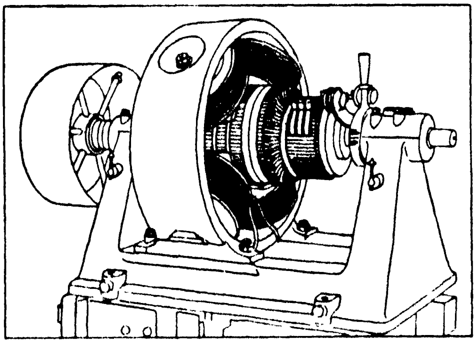
By Professor SILVANUS P. THOMPSON

Dynamo-electric Machines. This name, familiarly shortened into *Dynamo*, was originally coined (Greek *dynamis*, power) to denote a machine in which dynamic energy (that is to say, mechanical energy such as that given by a steam-engine or a turbine) is employed to produce an electric current. In recent years the term has been used, in its general sense, to include all machines the action of which is dependent on the principle discovered by Faraday in 1831, as explained in the preceding article, page 949. That principle was the induction of electric currents by the movement of copper conductors near the poles of magnets in such a way that the conductors cut through the invisible magnetic lines proceeding from the magnet poles. Faraday himself called such machines *magneto-electric*, and this adjective is still retained to denote those machines having a permanent magnet of steel, though Faraday did not so restrict its meaning, but applied it to cases in which steel bars, lodestones, electromagnets, and even the earth itself, were used as magnets. In Germany it has been the fashion to narrow its use to the particular class of machines in which the magnetism is excited by the current generated in the machine itself. On the other hand, the tendency in England now is to confine the term *dynamo* solely to machines which generate continuous currents, those which generate alternating currents being described as *alternators*, but to include those continuous current generators of which the magnetism is independently excited as well as those in which it is self-excited.



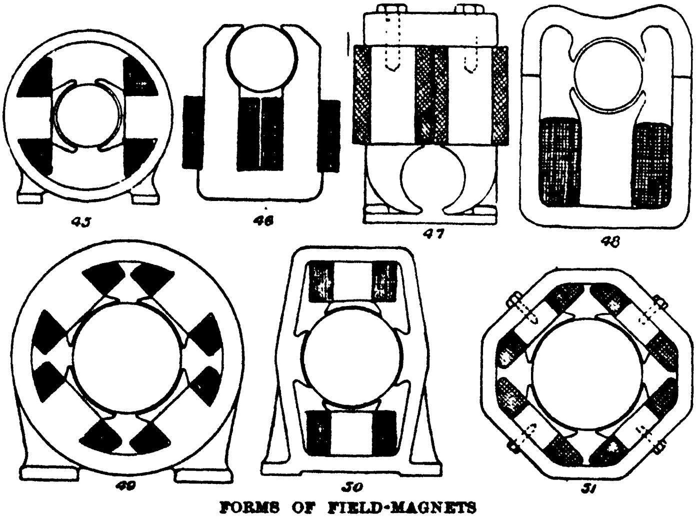
43. RULE OF THE RIGHT HAND

In most dynamos the copper conductors move, while the magnets are stationary; in some the magnets revolve while the copper conductors are stationary, but in the case of continuous current generators this is rare. It is even possible to design dynamos in which both parts revolve, but in opposite directions.



44. A MODERN DYNAMO

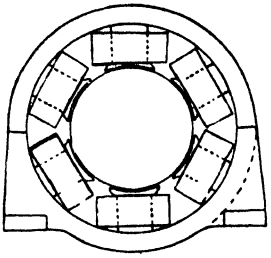
Principle of Reversibility. One most important fact about the dynamo—and it is true of all its many forms—is its reversibility of function. When driven by mechanical power it generates electric currents, but when supplied with electric currents it generates mechanical power. The very same machine that will serve to convert mechanical energy into electrical energy, as a *generator*, will also serve to convert electrical energy into mechanical energy as a *motor*. In fact, it possesses reversibility of function. This is indeed a most precious property, and is made use of in the electrical transmission of power from place to place.



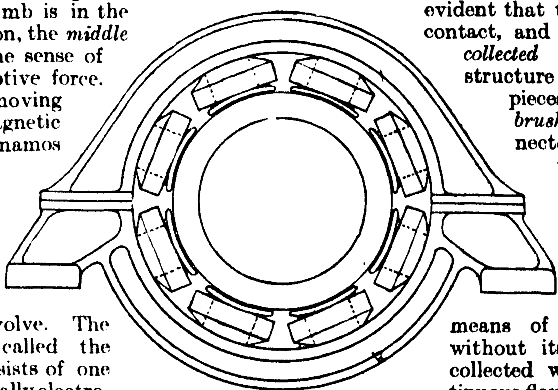
FORMS OF FIELD-MAGNETS

Right-hand Rule for Induction. The induction of an electromotive force in a moving wire, or conductor, tends to send a current along that wire in one direction or the other, and this direction can always be ascertained. In the movement of the conductor laterally across the magnetic lines, we have three things mutually at right-angles to one another—the magnetic lines, the direction of the movement, and the direction of the electromotive force. Now imagine the forefinger, the middle finger, and the thumb of the *right hand* to be set to point in three directions mutually at right angles to one another, as in **43**. Then, if the forefinger is set to point along the direction of the magnetic field, and if the thumb is in the direction of the motion, the *middle finger* will indicate the sense of the induced electromotive force. This is true for all moving conductors in magnetic fields, whether in dynamos or motors.

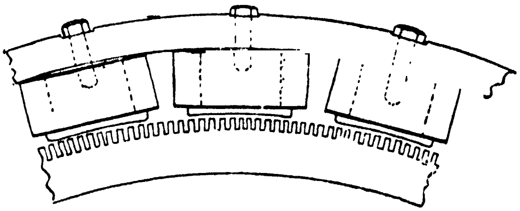
Field-magnets and Armatures. Every dynamo consists of two principal parts, one of which stands still, while the other is made to revolve. The stationary part is called the *field-magnet*. It consists of one or more magnets, usually electromagnets (page 562) firmly fixed in an iron frame the object of these magnets being to create a magnetic flux, or, in other words, to create a large number of magnetic lines which proceed from its poles. The revolving part is called the *armature*, and it consists essentially of a number of copper wires, or copper conductors, joined up together and grouped in a particular way for the circulation of the currents; these wires, or conductors being wound upon a core built up of laminated iron. In modern machines the cores are made with projecting teeth, and the copper conductors are sunk in slots between the teeth, and held in tightly by binding wires or by wedges. The core is keyed firmly upon the revolving shaft. So, when the armature is set revolving, the copper conductors are whirled round at a high speed. The revolving armature occupies a central position; and is surrounded by the poles of the field-magnet, which send their magnetic lines into the iron core across the intervening gap or clearance. The revolving copper conductors as they fly round cut these invisible magnetic lines, and so, according to Faraday's principle, create or induce electromotive forces. These electromotive forces tend to drive currents along the copper conductors, and so, if the revolving conductors are connected to a circuit, currents will be generated.



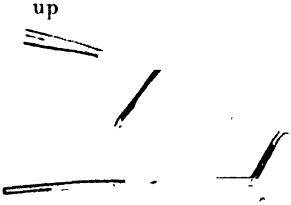
52. SIX-POLE FIELD-MAGNET



53. EIGHT-POLE FIELD-MAGNET



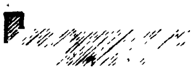
54. PORTION OF A 24-POLE FIELD-MAGNET



55. AN ARMATURE COIL

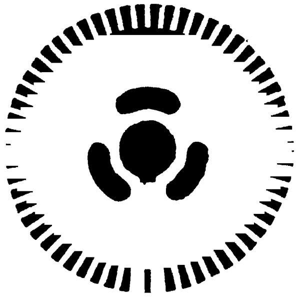
Commutator and Brushes. There arises, then, the problem how to connect the conductors of the revolving armature to the wires, or mains, of a circuit. It is evident that this entails a sliding contact, and the current must be *collected* from the revolving structure by means of contact-pieces, technically called *the brushes*, which are connected to the mains, and which press against the revolving structure.

The commutator, however, performs a function much more important than acting merely as a means of gliding contact, for, without its aid, the current collected would not be a continuous flow like the current from a battery. The reason for this is as follows. The poles of the field-magnet are of two sorts, north poles and south poles, arranged alternately. Since the revolving conductors on the armature are moved first past a north pole, then past a south pole, then past another north pole, and so on in continual succession, it follows that the induction of voltage in the conductors will continually reverse, and reverse back. For we may regard each north pole as sending out a flux of magnetic lines across the air gap into the body of the armature, from which these lines emerge to return into the south poles. Hence, if we apply the right-hand rule to the various cases, we shall see that the induction taking place in the conductors will alternate in its direction along the wire. This process, therefore, sets up alternating currents in the armature wires; and, unless these currents were commuted, they would be in a perpetual alternation in the mains of the circuit.



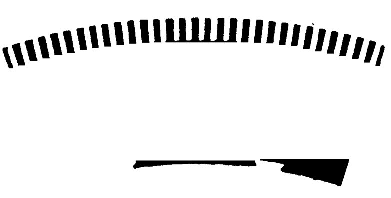
56. A COMMUTATOR SEGMENT

It is the function of the commutator to commute, or change, these alternating currents that exist in the armature, and deliver them to the external circuit as a "continuous" current. By *continuous* is meant *flowing steadily in one direction*, like the current from a battery. Some engineers call such a current a *direct* current, though its process of generation is thus indirect. The term "continuous" is more correct. How the commutator performs its work we shall see presently.

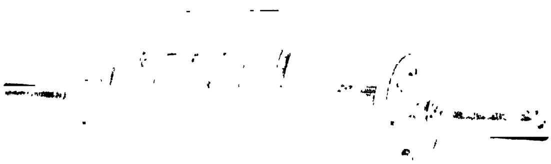


57. ARMATURE CORE-DISC (Sankey and Sons)

A Modern Dynamo. All essential features of a modern dynamo can be observed in the machine depicted in **44**. On the left is a pulley by which it can be driven by a belt from a steam-engine. The shaft is supported by bearings standing upon pedestals which rise from a strong cast-iron bed-plate. Between the pedestals stands bolted to the bed-plate the *field-magnet* system, consisting of a circular frame, or yoke, of cast steel, from which there project inwardly four massive magnet-poles, each surrounded by its magnetising coil. Between these four poles the *armature* revolves—a substantial barrel-like, or cylindrical, structure. At the right-hand end of the armature is the *commutator*—easily identified by noticing that it is a smaller cylinder built up of a number of parallel bars, or segments, of copper. Upon the commutator press the *brushes*. Of these there are two sets, of three brushes per set. The set of three in front can be seen clamped upon a short, horizontal rod, which projects to the left from the curved arm of the *rocker*, or frame, which carries the brush sets. The other brush set is behind the upper part of the commutator.

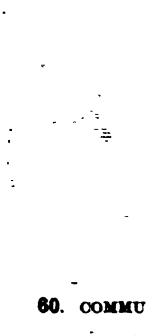


58. SEGMENT OF LARGE CORE-DISC



59. COMPLETE ARMATURE OF A DYNAMO

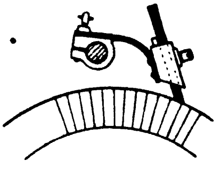
This particular machine is designed to run at 640 revolutions per minute, and to give out a current of 80 amperes at 250 volts. It will, therefore, at full load give an output of 250 × 80 watts—that is, 20,000 watts, or 20 kilowatts. And that it may do this one must put into it mechanically at least 20 kilowatts of mechanical power. Now (p. 290), 1 kilowatt = 1·34-horse power; therefore this machine will require $20 \times 1{\cdot}34 = 26{\cdot}8$ horse power at least. But in all machines there are certain losses due to friction, resistance, etc. If this machine has an efficiency of 94 per cent., then to get the 20 kilowatts (which are the equivalent of 26·8 horse power) out of it, we must put into it $26{\cdot}80 \times 100 \div 94 = 28{\cdot}5$-horse power.



60. COMMUTATOR

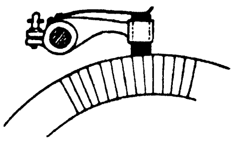
Forms of Field-Magnets. Almost all modern dynamos have four or more poles, but many old generators and many small motors of recent date have but two poles. Fig. **45** illustrates a *bipolar* form, suitable for small, enclosed motors, having the pole-cores projecting inwardly from the surrounding yoke. Figs. **46** and **47** illustrate other bipolar forms, the field-magnet being here a species of horseshoe, with its poles upward or downward. This form is still met with in open motors. Fig. **48** is a further development, in which the whole of the exciting coil is wound upon a single core. *Multipolar* forms are preferred for all large machines, and are illustrated in **49** to **54**. Fig. **49** is a four-pole form, practically identical with the magnets of **44**. Fig. **50** is a more special form, in which two of the poles only are wound with exciting coils, the other two being left unwound. Fig. **52** is a six-pole form, often used for machines of 100 to 300 kilowatts. Fig. **53** is an eight-pole tramway generator; it shows how the casting is divided into an upper and a lower half, and how the whole frame is supported. Fig. **54** gives a view of three poles of a large 24-pole generator of 2,000 kilowatts (2,680-horse power). In these large sizes the frame is stiffened by two projecting ribs that run round it. In many cases the ends of the poles next the armature are enlarged by the addition of *pole-shoes*. Fig. **51** is a four-pole form, made very compact, of the pattern much used for tramway motors.

Armature Cores. The core-body which receives the copper winding is nowadays always built up of thin *core-discs*, or stampings of very soft sheet steel, about $\frac{1}{50}$ in. thick. In small machines these core-discs are stamped out in one piece, like **57**, which has a central hole to admit the shaft, and ventilation holes. It is toothed at the periphery in order that when these discs, to the number of some hundreds, have been assembled on the shaft, the core body shall be furnished at its outer part with a series of longitudinal grooves, or *slots*, in which the copper windings can be placed. For armatures that are over 3 ft. in diameter the cores are built up of segments of thin steel, like **56**, attached by bolts or dovetail clampings to a central hub. The object of thus building the core bodies of assembled laminations is to prevent the waste of energy and consequent heating, which would occur by reason of parasitic currents induced in the mass if it were of solid iron. The thin sheets must be lightly insulated from one another by paper or lacquer.



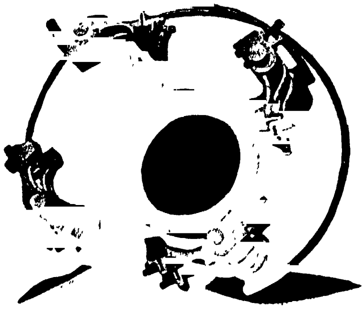
61. A COPPER BRUSH

Armature Windings. The conductors that are to be coiled on the core consist, in small dynamos, of copper wire, cotton-covered, and well lacquered. In very large machines they consist of drawn copper strip insulated by a covering of tape and lacquer. The proper number and arrangement of these conductors will presently be considered. In modern standard machines the coils of the armature are shaped upon wooden moulds, or *formers*, prior to being put into their places in the slots. Fig. **55** shows such a coil, consisting, in fact, of three separate coils taped up together for convenience in handling. They are curiously kinked, or twisted at the end-bends to permit of their being assembled in the slots, overlapping one another, each slot receiving two "sides" of coils, lying one above the other in the slot.



62. A CARBON BRUSH

Re-entrant Windings. The coils, after being put in place, are joined up together in a particular order, the end of one being joined to the beginning of the next, so that they form a continuous series, the end of the last one being finally united to the beginning of the first, and the whole series becoming, therefore, one re-entrant circuit. If a current be brought to any point of a re-entrant circuit, and leave that circuit at any other point, it will obviously have two possible paths of flow from the one point to the other. In every armature there are, therefore, at least *two paths* through the windings; and, as we shall see, there are often *more than two paths*.



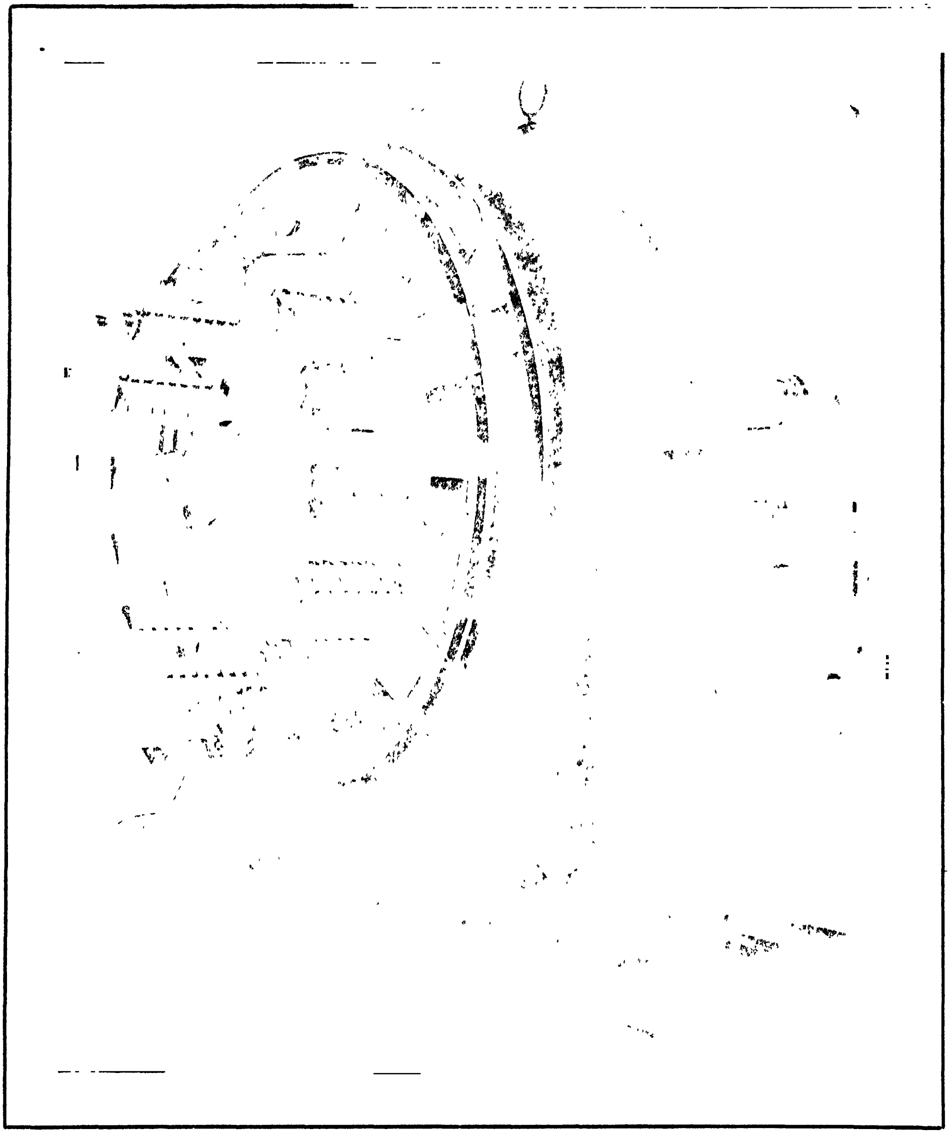
63. BRUSH GEAR AND ROCKER

Winding Pitch. Consider any loop of the winding, such as the loop shown in **55**. If a current is flowing around such a loop, it obviously will flow up one side and down the other. To drive the current around the loop by its own inductive action, as it whirls past the poles, it ought clearly to be of such a breadth from side to side that, while one side is passing under a north pole, the other side ought to be passing under a south pole, and then the two electromotive forces induced will help one another to drive the current around that loop [**63**].

Commutator Construction. The commutator consists of a number of bars, or strips, of copper, of a slightly tapering section assembled together to form a cylindrical structure, as depicted in **60**. The separate bars are insulated from one another with slips of mica, about 0·030 in. thick, interposed between them. The bars are shaped like **56**, with dovetail corners on their under side, so that they can be securely clamped between end-cheeks, and mounted on a shell, or hub, that is secured on the armature shaft. Insulating collars of built-up mica are interposed between the bars and the clamping cheeks of the shell, so that each individual bar is electrically isolated from contact with the neighbouring metallic parts. At the end of each bar of the commutator is attached a metallic strip, called a *riser*, by means of which the bar is connected to the armature windings. Thus, if the commutator has, say, 111 bars, there will be 111 risers connected to the winding, at 111 equidistant points.

Fig. **59** shows an armature complete, with the commutator. The dark markings show ventilating ducts between the windings. The end-bends, as well as the wires in the slots, are held down firmly by numerous bands of steel *binding wires*.

Brushes and Brush Gear. The name *brushes* was given to the stationary contact-pieces which collect the current from the commutator, because in the early machines they were literally made of bundles of springy brass wire. Nowadays, they are either made of bundles of *copper gauze* or copper strips, clamped in suitable *brush-holders* [**61**], or more often of blocks of fine *carbon* [**62**], held in holders, which press with a springy pressure upon the surface of the revolving commutator. In order to adjust the brushes to the proper position to collect the current without sparking, they are fixed to an adjustable frame called the *rocker*, which is itself borne upon the bearing, or else bracketed out from the magnet frame. Fig. **63** depicts a *brush rocker*, showing four sets of carbon brushes together with the pieces of flexible cable to connect them together, two and two, and to carry off the current to the circuit. There are two carbon brushes in each set. Fig. **64** depicts the *brush gear* of a much larger machine, having no fewer than 126 carbon brushes, arranged in 14 "sets" of 9 brushes



64. LARGE 14-POLE DYNAMO FRAME, SHOWING BRUSH GEAR

per set. Carbon brushes will collect from 30 to 40 amperes for each square inch of contact surface. Copper brushes need only about one-third as much contact surface as carbon brushes.

Calculation of Magnet Windings. To excite the magnetism in the dynamo, coils must be wound upon the pole-cores of the field-magnet ; or, rather, coils must be prepared with the proper number of windings of wire of the right thickness and with the right number of turns, being wound up on a lathe, and afterwards slipped into their places on the pole-cores. It is evident, therefore, that some previous calculation is necessary to enable the engineer to ascertain what windings will be right for any particular machine. Such calculations are made in two stages : first, to find the total amount of excitation, in *ampere-turns* [see page 563], that will be needed ; after that, to ascertain the particular size of wire and number of coils that will answer this need.

Conception of Magnet Circuit. It was pointed out on page 565 that, if in any magnetic circuit there are gaps—that is, if the magnetic lines have to emerge from the iron core into the air to cross the air-gap and then re-enter the iron—it will be necessary to provide a much greater circulation of current than would suffice to magnetise to the same degree if there were no gaps. The reason of this is that iron is much more permeable to magnetism than air is. Now, whenever the question arises how many ***ampere-turns*** of excitation are necessary, one must examine two preliminary conditions—namely, what is the nature of the magnetic circuit, and how great a flux is to be produced therein. In a simple horseshoe electromagnet, such as **23** [page 561], the magnetic circuit, or path, consists partly of iron, partly of air. The magnetic flux which emerges from the north-pole surface crosses a gap into the iron keeper, traverses the keeper, emerges again into the air opposite the south pole, crosses the gap again, and re-enters the iron core at the south pole, and follows the iron arch round to the north pole again. In a bipolar dynamo, such as **46** or **47**, the magnetic circuit is much like that of the horseshoe electromagnet, except that the gaps are very narrow. In a multipolar dynamo, such as **44**, **53**, or **54**, there are a number of independent magnetic circuits. For instance, in **54**, if the middle pole is the north pole, the magnetic flux that comes down the middle pole-core and crosses the gap into the armature core will divide, half the lines going to the right and recrossing the gap to go up the right-hand south-pole core, the other half going to the left to re-cross the gap under the pole core. In all such cases we have to calculate separately the excitation needed to send the flux through the different parts, and we must then total up the result for a whole magnetic circuit.

The calculation is complicated by the circumstance that there is always a little magnetic *dispersion*—*i.e.*, some of the flux which emerges from the pole does not cross the gap and enter the armature, but leaks by some lateral path to the neighbouring south poles. By experience we can ascertain how much to allow as a *leakage coefficient*. In ordinary multipolar dynamos 20 per cent. is an ample allowance.

Rules to Calculate the Excitation. For air-gaps, the rule is that the necessary ampere-turns are equal to the flux-density in the gap multiplied by the ***gap coefficient*** **0·3133.** In any iron part we have to calculate by reference to curves of statistics of the magnetism of iron of similar quality, and find from such curves how many ampere-turns per inch length of path are needed to produce in that kind of iron the required flux-density, and then multiply up the figure so found by the number of inches' length of that part.

For example, if we had the four-pole dynamo [**44**] ready built, but still requiring its winding, we should know that the flux from the pole was to be 2,700,000 lines net, or (allowing 20 per cent. for dispersion) 3,240,000 lines in the pole-core. Further, if the area of pole surface is 56 sq. in., the flux-density in the air-gap will be 48,000 lines per square inch. Also, if the pole-core section is 50 sq. in., the density in the iron will be 65,000 lines per sq. in. Moreover, if the teeth are so narrow that the effective section of those under one pole is only 20 sq. in., the density in them will be 135,000. Now, suppose the air-gap to be ½ in. wide, the teeth 1 in. long, the pole-core 8 in. long. Also suppose the curves of statistics to show that to produce a flux-density of 65,000 in the mild steel of the pole-cores required 14 ampere-turns per inch, and to produce a density of 135,000 in the armature stampings required 1,200 ampere-turns per inch, we then have the following calculation for a magnetic circuit.

A.-T needed for 2 air-gaps	= 2 × 48,000 × 0·3133 × 0·5	= 15,038
A.-T ,, 2 teeth	= 2 × 1,200 × 1	= 2,400
A.-T ,, 2 pole-cores	= 2 × 14 × 8	= 224
A.-T needed for one piece of core-body and one piece of yoke, say,		= 800
Total ampere-turns needed per pair of poles		= 18,462

Hence, each pole must carry wire enough to provide 9,231 ampere-turns.

To find the right size of wire we have the rule that it must be such that its resistance per inch length will be equal to the voltage divided by the required number of ampere-turns and by the mean length per turn of the coil. Now, this dynamo is for 250 volts, so that there will be available (allowing 30 volts for regulating rheostat) 220 volts—*i.e.*, 55 volts for each of the four coils. The mean length of one turn will be about 35 in. Hence the wire must have a resistance of 55 ÷ (9,231 × 35) = 0·00017 ohms per inch length. Reference to wire-gauge tables shows that this will be a No. 15 S.W.G. wire, the diameter of which is 0·072 in.

TAILORING FOR WOMEN & CHILDREN

Pressing Tools. Stitches used in Tailoring. Drafting Little Boys' Suits. Taking Measurements. Front and Back Drafting

By Mrs. W. H. SMITH and AZÉLINE LEWIS

PRESSING TOOLS

The Iron (called by tailors "Goose") is the first thing required, and should be at least 10 to 15 lb. in weight.

The Sleeve-board can be made at home. A piece of wood, well seasoned and free from knots, ash or beech, 1¼ in. thick and 23 in. long, 5 in. wide at one end, and from 2½ to 3 in. at the other, will be large enough for boys' and ladies' tailoring [1].

There is also the duplex sleeve-board, which is far more useful but a little more difficult to make. This is used for pressing seams, the bottoms of sleeves, trousers, etc. [2].

The Sleeve Headboard is, as its name implies, for pressing the top of sleeves. It is useful for pressing such parts as the darts, and any part where the figure is round; also for the bottom of boys' knickers when they are gathered into a band [3].

Damping-cloth. This should consist of ¾ yd. of thin silesia (6½d. a yard), well washed to get every particle of dress out before use. It must be kept perfectly clean; the water and the vessel for it being absolutely clean and free from grease. The cloth must not be very thick or it will retain too much moisture; and as its object is to supply only sufficient dampness to raise steam, it should be wrung as dry as possible before using.

Brown paper, tailor's crayon, a square, pencil, bodkin, tracing-wheel, and wax, are also required for drafting, cutting-out, and making.

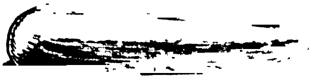
2. DUPLEX BOARD



3. SLEEVE HEADBOARD

STITCHES USED IN TAILORING

Thread Marking. This stitch must be put into all inlays and inturns—*i.e.*, neck and arm-hole curves, shoulders, pockets, revers, fronts, bottom, sleeve, cuff, etc., to ensure that both sides of the garment are made up exactly alike [4].

Place together the two corresponding portions, and with a double thread work small "running" stitches through both, on the line to be marked, leaving a small loop to each stitch. Cut the loops, draw the two pieces of material slightly apart, and cut the threads between them; *a* shows the first process, *b* the second, *c* the result when the stitches are cut between the cloth.

Serging. This is a very useful stitch for several purposes, such as joining together two pieces of material that are likely to fray, also the pleats of Norfolk jackets and the turnings of bottoms of skirts and sleeves to canvas; in fact, in tailoring, serging is indispensable.

The stitch is formed by passing the needle from back to front of the cloth. It must not go too deep nor be pulled too tightly. This form of stitch should, moreover, neither lie too closely together nor should the stitches overlap each other, as a rough, hard ridge would result, and the object is that the two pieces serged together should lie perfectly flat when pressed [5].

Tailors' Felling. This is an important stitch, as no tailor-made garment can be completed without it; it is used for holding in well-basted linings of every description.

Place the needle in the lining quite close to the edge of the material it is to be felled to, in a slanting direction towards the worker, taking as small a stitch as possible in the material, so that when pulled out it will take hold of the lining. Next insert the needle in the cloth opposite to where it came out of the lining, pull out, and again catch the lining, repeating this till the work is finished. The space between each stitch should be, for fine work, $\frac{1}{16}$ in. apart, for medium ⅛ to ¼ in.

The sewing should not be visible on the upper edge of cloth or material to which the lining is felled.

Top Felling. This is done by putting the needle first through the top instead of the under side; it will keep thick fabrics in place better than ordinary felling stitch, and will hold the cloth down much better. By placing the needle in a slanting position the top side can be put on tight or full, as required, according to the slope of the needle, with a proper hold of the cloth [6].

Back-stitching. This is used to sew up seams, linings, pockets, etc. Place the needle as upright in the hand as it can be conveniently held, then push it through the cloth, straight down and straight up. The next stitch must be put in the hole the needle has just left; pull the thread up as lightly as the fabric requires. Thick cloth must be pulled up firmly; thin cloth gently, and so on.

Side-stitching. This is used on the edge of coats, vests, jackets, etc. It is made by placing the needle on one side of the stitch—

14. BUTTONHOLE.

that nearest the edge is best—and should be as small as it is possible to make it. Pull the needle up rather firmly, so as to sink the stitch into the cloth ; a little dot made by the stitch is all that should be seen [7].

This is the neatest stitch for the outside work of garments, and, if well done, keeps the edges from rolling.

Padding. This stitch is used to force canvas on to the turns or revers of coats and collars of all kinds of garments that require canvas to hold them in place.

The cloth must be held in a rolled manner over the fingers, and the stitch taken as lightly as possible on the cloth, only showing a small dot on the under side. It is worked up from right to left, and down from left to right, about ¼ in. apart, forcing the canvas on a little each time a stitch is taken—*i.e.*, working the cloth from underneath with the forefinger, and pushing the canvas very slightly with the thumb, to make the work form a roll [8]. Each row must be the same distance apart, and each stitch midway between those on previous row. To produce good results Raven silk should be used ; it is to be bought in skeins, and can be had at any tailors' trimming warehouse.

Back and Fore Stitch. This is useful where strength is not required. Make two back stitches and one forward, then one back and one forward all through. This is useful for sleeve linings and other light work, such as linings of skirts and jackets [9].

Rantering. This is used to close up a seam that looks unsightly, the object being to make it invisible.

First sew the seam with back stitches about ⅛ in. apart, taking the needle back half way into the previous stitch all through. To produce thin results the work must be done with fine needle and silk [10*a*].

After sewing the seam, double the edges back on the right side, working them as close to the edges as possible with the finger and thumb. Take a fine needle and silk, pass it in a perfectly straight line (from and towards the worker) through the extreme top of the edges, between every thread of the material; this is important, as the seam must lie perfectly flat [10*b*]. When finished, scratch the edge of the material lightly to raise the nap ; then, also very lightly, press the wrong side on a bare board. On no account draw the iron along.

Stoating. First place the edge of the material together, wrong side up, and mark at regular intervals of at least 1 in. with a tailor's crayon. The edges are then held together by the left forefinger and thumb, and the needle is passed in a perfectly straight position from the top through half the thickness of the material—*i.e.*, splitting the cloth. The stitches must on no account show on the right side. It should also be remembered that in drawing it up, the stitch should be pulled rather tightly. Stoating is best applied on stout, firm cloth, the edges of which will admit of splitting, such as Meltons, beavers, boxcloth, etc. Fig. 11*a* will give some idea of the way this form of stitch is applied.

The chalk marks must be kept opposite each other all through. When the seam is finished it should be rubbed with warmed wax, placed on a bare board, wrong side up, slightly damped, and pressed with a rather hot iron, which must be lifted up, *not* moved along. Fig. 11*b* shows the process completed and right side of cloth.

Drawing-stitch. This is applied on the right side of material without any seams being taken. It is employed for joining the ends of collars to revers, etc. Use a very fine needle and silk. After securing the first stitch [12], place the needle in the top of rever, bring it round, taking the smallest possible hold of the collar; bring the needle up tightly, insert it again directly opposite where the last stitch came out, and proceed as before. Mark the edges as in stoating to keep them even, and press when finished.

Buttonholes. First mark the position of the holes at equal distances apart. The eye of the hole should be ⅜ in. from the edge of the garment and ¼ in. longer than the diameter of button. No matter what the material may be, it is advisable to stitch round the mark before cutting, to prevent the top and under edges from slipping; this enables one to work the hole with more ease [**13**].

Holes are usually barred with double twist, thread, or gimp. Twist is preferable, as it wears so much better, and should always be used in the best work; the two latter methods cut the twist, and give to the holes a stiff appearance which they should not have.

To "bar" the hole, a No. 5 needle and No. 10 twist will be required. Take a length of twist from ¾ to 1 yd., according to size of buttonhole, and make as small a knot as possible. Insert the needle between the cloth and facing to hide the knot, bringing it up as near the edge as possible [**14**]; send it down at 2, up again at 2, down at 3, up again at 3, and down at 4. The twist should be drawn rather tightly, and lie along the hole at an equal distance from the edge. Repeat the operation, which will produce a double twist bar. Fig. 13*a* shows the hole cut and barred, and the needle placed in position, before making the first stitch. Bring the needle up at 1, about 1/16 in. from the edge, cast the two threads which hang from the eye of the needle round the point, from right to left [*a*], draw the needle out in an upward and forward direction, taking care to have the loop, or purl, exactly on the edge of hole, and continue the stitch to 2 (2 and 3 represent the eye of the hole). The stitches should now be closer together, the purl pulled well up at this point, and the eye kept as round as possible; complete the hole in the same way as from 1 to 2.

Now bar the end. To do this, hold the garment with the eye of the hole towards you, make 3 or 4 bars from 4 to 1, bring the needle up at 4 and make 3 or 4 loop stitches, put the needle down at 1, fasten off neatly and securely.

The holes are now ready for the finishing process. Press the two edges together with the thumb and finger, oversew lightly with two or three stitches near the eye, place a cloth over the hole and press, insert a bodkin or stiletto in the eye, and give two or three sharp turns. The buttonhole is now completed [**13*b***].

DRAFTING BOYS' SUITS

In drafting and making boys' garments—that is, little boys from about 6 to 8 years old—it is of the greatest importance that they should be easy in fit, yet not so big as to be unsightly. Extremes in either case must, of course, be avoided; a tight fit for boys is certainly a mistake, and is not conducive to health. In the case of tall, thin boys, it exaggerates the slimness, and for those of opposite build, it accentuates the stoutness; in neither case does it add to the beauty of proportion. Coats for slim boys should hang as straight as possible from the back of arm to bottom of coat, to broaden the figure.

Having thus dealt with the necessary preliminaries, we can proceed with the drafting of a boy's suit for the following measures—*viz.*, 26 in. breast, 26 in. waist, 12 in. neck, 12½ in. back, 19 in. full length, sleeve from centre-back to wrist 22½ in.

Measurements. Round the lower part of neck, 12 in.

Back. Place the end of inch tape on the nape of neck (to do this correctly, you must feel for the small round bone that connects the vertebræ or backbone, with the bones of the neck), measure to hollow of waist, 12½ in., on to full length, 19 in.

Round the chest—not tightly—26 in.

Sleeve, from centre-back, on to wrist, 22½ in. Working scale: half breast, 13 in.; ¼ in. turnings are allowed on all seams.

The Drafting. A piece of paper 20 in. long and 18 in. wide is required. Square lines 1½ in. down from the top and 1 in. in from edge. Letter the left-hand corner A.

Back Drafting. A to B, one-sixth of back length (2¼ in.), A to D, length of back (12½ in.); B to C, one-third (4⅜ in.); A to E, full length (19 in.); E to E^a, ½ in. Draw line from E^a to A; square lines at right angles from B, C, D, and E. A to A^a, one-sixth of neck; A^a to A^b, ½ in.; from back line to C^a, one-third of breast, plus 1¼ in. (5½ in.); to F, two-thirds; to G, half breast; to H, 2½ in. more than the measure.

Square line from C^a to B line; C^a to I, one-twelfth; I to I^a, ½ in. Make J top of line on line B; back line to J^a, half the distance from A to C (see broken line). Draw line from J through C^a to bottom of coat and make K. K to 1, one-twelfth (about 1 in.); 2 and 3 are ¼ in. to right and left of K line. Draw lines from K through 2 to C^a.

Curve from I to J; slightly curve back-shoulder line from J to A^b; and neck from A^b to A [**15**].

Front Drafting. F to F^a, one-sixth, plus ½ in.; F^b is midway between. F^b to X, ½ in. Square line up from G to neck line, make L, continue line G to bottom of coat. L to M, one-sixth of neck; M to M^a, ¾ in.; M^a to N, one-sixth of neck.

Square line from M^a and N to 1½ in. out from G line; make H^a. N to N^a, half the distance from M^a to N; G line to P, ½ in. more than G to H. Draw line from H through P, to bottom of coat; mark off the corner 1½ in. (or more if desired).

Curve from G line through this point to ¼ in. out from P, on to H; slightly curve from H to H^a.

Neck Line. Curve from H^a through N^a to M^a; draw front shoulder from M^a to J. Make O same length as back shoulder; drop O ¼ in. before curving, to take off the sharp angle at that point. Curve from O, through F^a, X, and F to I^a and from E through 3 to I for side of front [**15**].

HOW PLANTS PROTECT THEMSELVES

Defences of Seed-plants against Weather and Animals. Life History of the Fern. Alternation of Generations. Fern-like Plants

By Professor J. R. AINSWORTH DAVIS

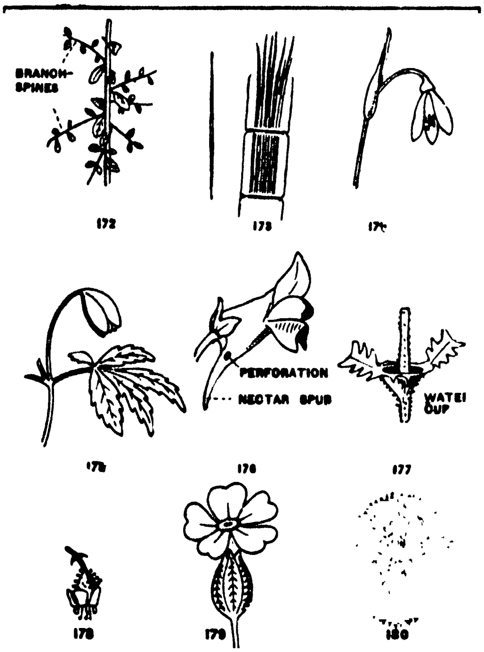
Defences of Plants. Enough has already been said about the way in which drought-plants (*xerophytes*) tide over the unfavourable season of the year, and this must serve as a partial illustration.

The numerous cases where plants possess spines, thorns, prickles, etc., are partly at least to be interpreted as adaptations whereby defence against many vegetarian enemies is more or less attained. In the sloe (*Prunus communis*), for example, the spines are modified branches [**172**]; in gorse (*Ulex Europaeus*) they are branches and leaves; and in cacti, leaves (*Echinocactus*), a photograph of which [**135**] appears on page 909; while in holly (*Ilex aquifolium*) the prickly leaves answer the same purpose.

The grubs of many beetles live in wood, upon which they feed. This probably gives a clue to the primary use of the important commercial substances india-rubber and gutta-percha, which are the dried sticky juices of various shrubs and trees living in hot climates. Beetles of the wood-boring kind, which seek to pierce and lay eggs in such plants, are liable to be snared and killed by the viscid fluids which ooze out.

Arums, and various other plants, ward off the attacks of snails and slugs in a rather curious way. The outer parts of their stems and leaf-stalks contain bundles of excessively sharp crystals (*raphides*), composed of oxalate of lime [**173**]. These pierce the soft mouths of snails and slugs like so many needles, conveying a lesson which is usually taken to heart.

Readers who have followed this course will realise the importance of the fertilising dust known as pollen. Since it is very liable to be spoilt by moisture, a number of devices have come into existence by which this is prevented.



172. SLOE. 173. RAPHIDES (slender needle-like crystals). 174. SNOWDROP. 175. WOOD ANEMONE. 176. TOADFLAX. 177. TEASLE. 178. GOOSEBERRY. 179. SILENE INFLATA. 180. SWEET CHESTNUT (rounded husk covered with slender spines).

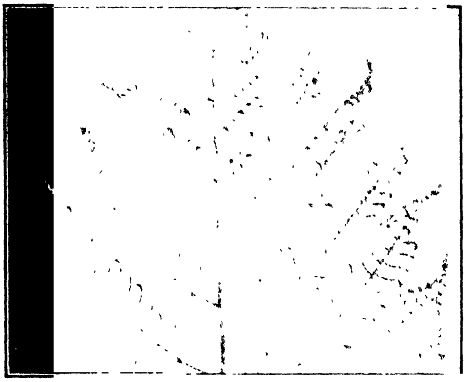
Bell- or cup- shaped flowers hanging upon curved stalks protect their pollen very effectually, as may be seen in Canterbury bell (*Campanula*), heath (*Erica*), snowdrop (*Galanthus*) [**174**], and lily of the valley (*Convallaria*). There are also many flowers which bend over in rainy weather so as to shield the pollen, among which are herb Robert (*Geranium Robertianum*), daisy (*Bellis perennis*), willow herbs (*Epilobium*), and wood anemone (*Anemone nemorosa*) [**175**]. In other cases—*e. g.*, lime (*Tilia*), an illustration of which [**146**] appears on page 911, and balsam (*Impatiens noli-me-tangere*) — the foliage-leaves serve as an umbrella.

In many members of the dead-nettle and foxglove orders (*Labiatæ* and *Scrophulariaceæ*) the opening of the corolla is at the side: or in some of the latter, such as toadflax (*Linaria*) [**176**] and snapdragon (*Antirrhinum*) it is completely closed except during insect visits.

The closing of many flowers on the approach of rain is a common device by which pollen is protected, and is exemplified by roses, gentians, and crocuses.

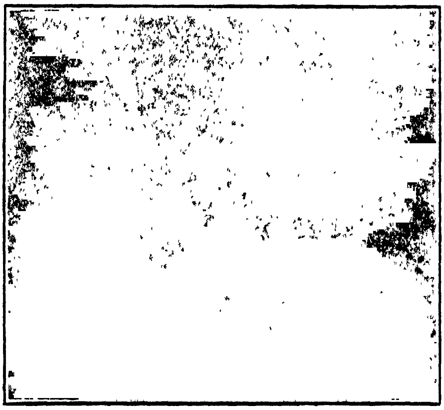
Protection against Unbidden Guests. While flowers lay themselves out, so to speak, to attract insects of a certain kind which are able to transfer pollen, the flowers themselves, or the pollen and nectar they provide as rewards for their industrious servants, prove tempting to other insects, and sometimes to snails and slugs, which are unable to perform the work required of them. Such "unbidden guests" are debarred from access to the flowers by a great variety of ingenious devices.

The flower must also be protected against unbidden guests which creep up from the ground. These are mostly creeping insects, which find their upward progress barred by water barriers, slippery or sticky surfaces, or obstructions of bristles or sharp hairs. In certain teasles (*Dipsacus*) [177], for instance, the foliage-leaves are in opposite pairs, and their bases unite together to form a cup in which water accumulates. Some of the catch-flies (*Silene*) and campions (*Lychnis*) have sticky stems, which not only prevent the visits of undesirable forms, but entangle and hold them so firmly that they perish miserably, and in gooseberry (*Ribes grossularia*) [178] there are viscid hairs on the calyx which answer the same purpose. In certain willows (*Salix*) approach to the flowers is prevented by wax-covered slopes as slippery as glass, which give no foothold, while a curved flower-stalk, such as that of snowdrop (*Galanthus nivalis*) [174] may debar entry. Obstructions are well seen in the prickly bracts which closely invest the flower-heads of thistles.



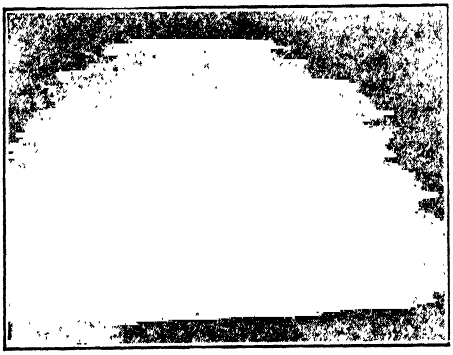
181. FERN

182. HORSETAIL



183. HAIR MOSS (Polytrichum)

There are some plants, such as certain balsams (*Impatiens*) which secrete nectar at the bases of their foliage-leaves to attract unbidden guests which are climbing up to the flowers. Ants, in particular, are very fond of sweet substances, and commonly content themselves with this lure, which saves them the trouble of going further. Snails and slugs are effectually kept away by spines, thorns, and prickles, as in gorse (*Ulex Europæus*), sea-holly (*Eryngium maritimum*), and many others. These unbidden guests do not seek pollen or nectar, but devour the flowers bodily



183A. MOSS

(Photographed by Prof. B. H. Bentley)

Many of the more specialised flowers can only be usefully served by a limited circle of visitors, and others have to be excluded. Tangles of hairs or gratings of bristles are often found within the flower itself, and effectually protect the nectar against smaller and weaker insects. Such may be found in the buckbean (*Menyanthes*), some honeysuckles (*Lonicera*), and some speedwells (*Veronica*), while in many instances the mechanism of the flower may be compared to a lock of which only the legitimate visitors possess the key. This is well exemplified by most members of the pea and dead-nettle orders (*Leguminosæ* and *Labiatæ*).

There are several thieving bees with tongues too short to reach the nectar-stores of certain flowers, and these intelligent creatures have found it possible to bite through the outer investments and steal the desired treasure without earning it [176]. One device for preventing this is found in the bladder campion (*Silene inflata*), where the large inflated calyx stands at some distance from the treasure-house [179]. Should a nectar-thief gnaw a hole through this it is no better off than before, for its tongue is too short to stretch through to the nectar.

Many flowers of pale hue which court the attentions of moths only exhale a fragrant odour in the evening, when their guests are on the wing, and may even remain closed during the day. In this way they to some extent escape the notice of undesirables. Honeysuckle (*Lonicera*) may serve as an example.

There are also some plants which maintain a body-guard of ants to repel the attacks of voracious beetles, but do no harm to the flowers. These plants belong to the dandelion order

(*Compositæ*), and they reward the services of their retainers by nectar, which is secreted by the scales surrounding the heads of flowers.

We have seen that many fruits are destined to be eaten by birds or other animals, the strongly coated seeds escaping digestion. But it is necessary that such fruits should be protected while they are ripening. For this purpose many of them are enclosed in prickly husks, as sweet chestnut (*Castanea*) and beech (*Fagus*) [**180**]. Still more commonly the unripe fruit is acid, bitter, or even poisonous, and is thus effectually shielded from most attacks. Seeds, when mature, are frequently so flavoured that they do not commend themselves as an article of diet.

Certain other methods by which fruits and seeds are protected have been already spoken of in the section on "Dispersal" (page 909).

The highest group (*Pteridophytes*) of the seedless plants contains many familiar forms, among which ferns and their allies (*Filicinæ*) take a leading place. It also includes horsetails (*Equisetinæ*), and club-mosses (*Lycopodinæ*).

Former Importance of Fern-like Plants. That part of the geological history of the globe during which we know positively that organisms existed is divided into three great epochs—Primary, Secondary, and Tertiary. The last and shortest of these, which includes the present period, is characterised by the dominance of pod-plants (*Angiosperms*) on land, while naked-seeded plants (*Gymnosperms*) were supreme during the much longer Secondary epoch. Before this, in the immense period of time embraced by the Primary epoch, fern-like plants played by far the most important part in the vegetation of the land. During a part of this epoch the coal-measures of Britain slowly accumulated, and they are chiefly made up of the remains of such plants, some belonging to groups which are now entirely extinct, while others are represented at the present time by species which are mostly small or even of insignificant size.

FERNS (Filicinæ)

Tree Ferns [**184**]. The hot, damp forests of tropical and sub-tropical regions may be regarded as the headquarters of the fern group. In parts of the southern hemisphere—notably Ceylon, Australia, and New Zealand—some ferns grow to the size of trees, and may even make up forests. They somewhat resemble palms in appearance, consisting as they do of a long, bare trunk, bearing a crown of feathery leaves.

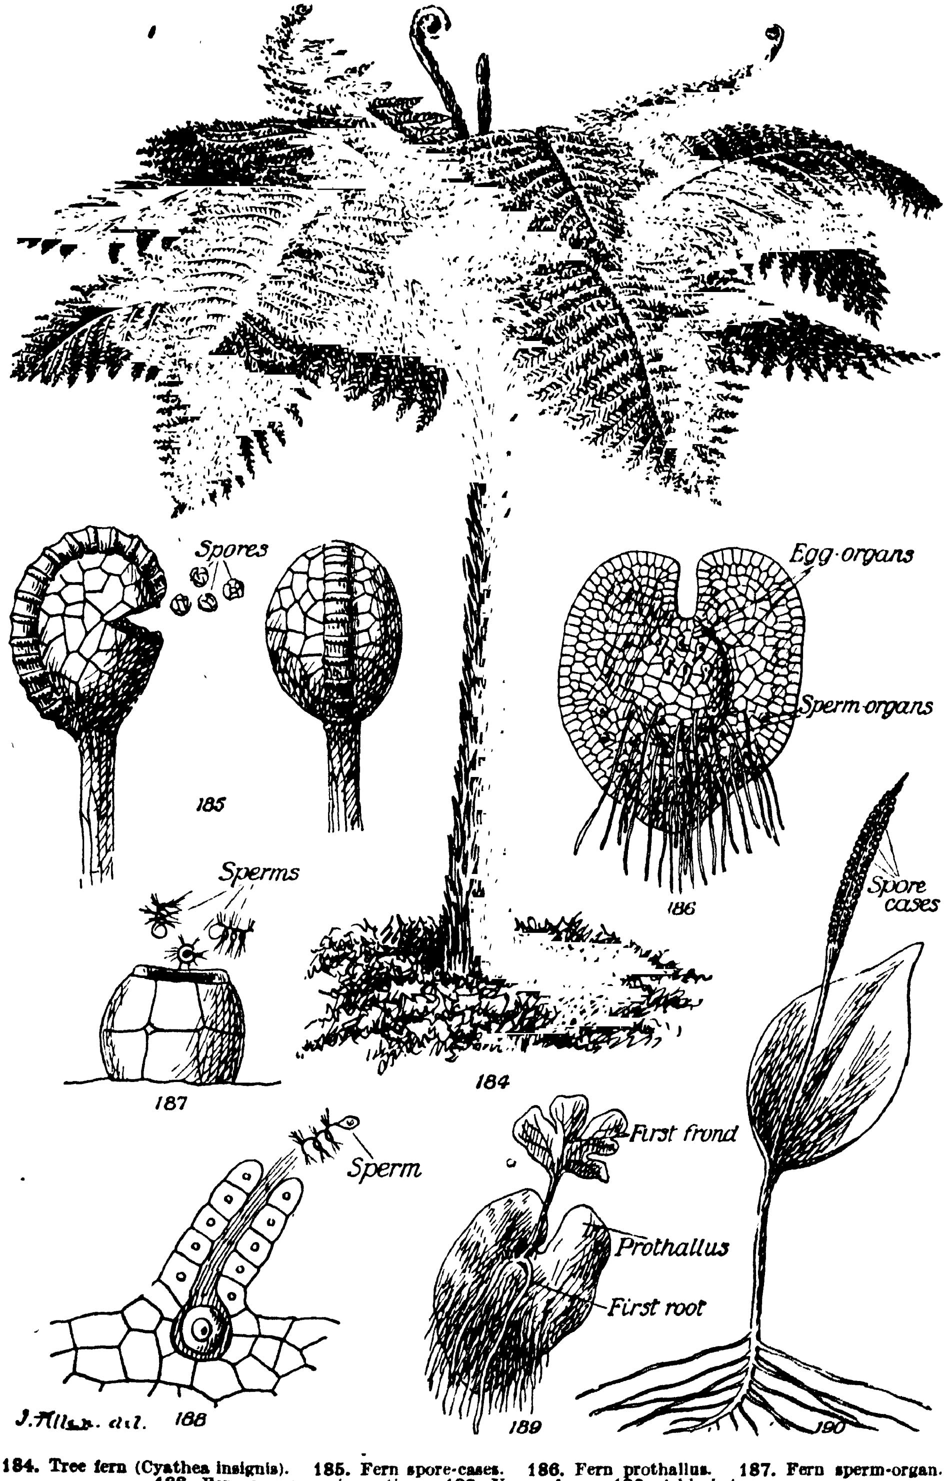
Parts of a Fern Plant. A fern plant of the kind familiar in this country generally consists of an underground stem (rhizome), which may creep horizontally at some distance below the surface, as in bracken (*Pteris aquilina*), or may be obliquely embedded in it, as in male fern (*Aspidium Filix-mas*). The stems of other species are attached to the bark of trees, or find a home in the crevices of walls or rocks. Brown branching roots grow out from the stem, and serve, as usual, the double purpose of fixation and absorption of a part of the food. The leaves or fronds grow in the contrary direction into the air and light, and do the same work as in seed-plants. They are sometimes broad and unbranched, as in the hart's-tongue (*Scolopendrium*), but their shape is commonly more or less feather-like [**181**]. Young fern fronds are rolled up in the shape of a bishop's crosier, and are thus enabled to force their way up through the soil without getting damaged.

The Life History of a Fern. Probably everyone has noticed regularly arranged brown patches on the backs of fern fronds [**181**]. Each of these is termed a *sorus*, and species differ considerably according to the shape of sori and their manner of distribution. In bracken they are close to the edges of the frond, and follow its outline ; in hart's-tongue they are long streaks diverging from the middle of the leaf, while in polypody (*Polypodium*), so common on tree-trunks, and male fern they are round patches [see also **181**]. A sorus may have no special investment, as in polypody, or it may be covered by a membrane (*indusium*), as in male fern. In some cases there are special fertile fronds of different shape from the others, upon which the sori are borne, instances being afforded by the hard fern (*Blechnum boreale*) and royal fern (*Osmunda regalis*), the latter being our largest native species.

Spore-cases and Spores. Examination of a sorus under the microscope shows that it is made up of a number of stalked spore-cases [**185**], in which are contained a number of angular brown spores. A spore-case is of biconvex shape, with a thickened ring (*annulus*) running round the greater part of its margin. This band is in a state of tension, and when the spores are ripe it tears open the case and scatters them in all directions.

Germination of the Spores. The spores are cells of simple structure, and must not be confounded with seeds, for, as we have already learnt, these are of very complex character. A spore, too, is not, like a seed, the result of a process of fertilisation, but is asexually produced. Should it reach a damp spot it at once germinates. Its firm coats split, and two outgrowths make their appearance—a delicate, colourless, root-hair which grows down, and a green thread that makes its way upward. But few spores are able to effect their work of continuing the species. It has been calculated that, on an average, only one spore per plant succeeds in doing this each season. And if these little bodies were not produced in vast numbers, ferns would soon become altogether extinct. We should naturally expect that the germinating spore would grow at once into a new fern plant ; but this is not the case. It gives rise to a small heart-shaped, green expansion, the *prothallus* [**186**], attached to the soil by numerous root-hairs. Prothalli may often be seen in quantity in greenhouses, growing on the mould in which ferns have been planted. The artificial conditions are very favourable to their production.

Egg-organs and Sperm-organs. Upon the under side of the prothallus, in its central region (the cushion), which is thicker than



184. Tree fern (Cyathea insignis). **185.** Fern spore-cases. **186.** Fern prothallus. **187.** Fern sperm-organ. **188.** Fern egg-organ in section. **189.** Young fern. **190.** Adder's-tongue.

its edges, will be found a group of egg-organs [188], each of which consists of a basal part, embedded in the prothallus, and containing an egg-cell, and a projecting curved region. Scattered about on the same side of the prothallus, but restricted to its thinner part, are a number of very minute hemispherical projections, the sperm-organs [187], in each of which are produced a quantity of excessively small sperms, shaped like fragments of corkscrew, and beset with delicate threads of protoplasm, in constant movement, enabling the sperms to swim about in the film of moisture covering the prothallus.

Fertilisation. Within the mature egg-organ a sort of slime is produced, which swells up and forces apart the cells making up the projecting portion, so as to leave a passage down to the egg-cell. Meanwhile, the ripe sperm-organs have been burst open in similar fashion, and the liberated sperms swim actively about. The slime which oozes from the egg-organs exerts a chemical attraction upon them, and should a sperm succeed in making its way down to an egg-cell it fuses with it. This act of fertilisation is precisely comparable to the process described under the same name for seed plants And it is particularly interesting to notice that among the lowest of the latter (*Cycads*), the pollen-grain gives rise to motile sperms, instead of growing out into the usual pollen-tube.

Development of the Fertilised Egg-cell. The fertilised egg-cell at once begins to divide, and soon gives rise to a young fern-plant [189], which remains for a time attached to the prothallus, but ultimately drops off and takes root in the ground. The prothallus now perishes.

Alternation of Generations. We see, therefore, that the life-history of the fern includes two alternating stages: (1) The ordinary fern plant, which produces spores asexually, and (2) the prothallus, possessing egg-organs and sperm-organs. We may call these the *Spore-generation* and the *Egg-generation*, and show their relationship thus:

$$\underset{\text{(fern plant)}}{\text{SPORE-GENERATION}}\text{—spore—}\underset{\text{(prothallus)}}{\text{EGG-GENERATION}}\left\{\begin{matrix}\text{Egg-organ—egg-cell}\\ \text{Sperm-organ—sperm}\end{matrix}\right\}\begin{matrix}\text{Fertilised}\\ \text{egg-cell}\end{matrix}$$

This remarkable phenomenon is known as "alternation of generations," and is typically seen in fern-like plants, mosses, etc., and many lower forms of plants. It is also characteristic of seed plants in a somewhat modified form.

FERN-LIKE PLANTS

Adder's - tongue and Moonwort. These small and rather uncommon British ferns differ in several ways from their allies just described, for they possess but a single leaf, which divides into a sterile and a fertile part, while each spore-case develops from a group of cells, and not from a single one, as is the case in an ordinary fern. In the adder's-tongue (*Ophioglossum*) [190], the sterile part of the leaf has a simple outline, while the elongated fertile portion is practically a mass of closely crowded spore-cases. But in moonwort [191] both parts of the leaf are branched in a feather-like manner.

Water-ferns (*Hydropteridæ*). These make up a small but interesting group of little plants which are either purely aquatic, or grow with some exceptions in swampy ground.

The lake quillwort (*Isoëtes lacustris*) [192] is found in this country growing at the bottom of mountain lakes, from North Wales northwards, and looks at first sight like a stoutly built grass. But it is in reality a relative of adder's-tongue and moonwort, and if, during the summer, we examine the inner sides of the bases of its leaves, we shall find that each of them bears a comparatively large spore-case. As in all the water-ferns, these are of two kinds, which respectively contain small spores and large spores, and having regard to the fate of these we may call the leaves which produce them *male spore-leaves* and *female spore-leaves.* For a small spore germinates to produce a minute male prothallus with a single sperm-organ, while a female spore gives rise to a rather larger female prothallus, which bears a few egg-organs.

Of the remaining members of this group, which are more nearly related than quillwort to ordinary ferns, the first to be considered is salvinia [193], a small aquatic plant, native to South Europe. It is entirely devoid of roots, and consists of a stem bearing two kinds of leaves, some being oval and floating on the surface, while the others are finely divided and submerged. The latter play the part of roots, and they are also fertile, for at their bases are found rounded sori containing large-spore and small-spore cases. The spores germinate within these in much the same way as in quillwort.

Marsilia [194] grows in marshy ground, and is represented by European and Australian species. There is a creeping stem, from the under side of which roots are given off. The long-stalked leaves fork into a sterile and a fertile portion, the former terminating in a blade which is divided into four parts, and somewhat suggests wood-sorrel in general appearance. The fertile section ends in a hard, bean-shaped structure, which may be called the *spore-fruit*, and contains a number of spore-cases, of which some enclose large and others small spores. When these are ripe, part of the internal tissue of the fruit is converted into mucilage, which swells up and splits open the firm investments along one side. The spores now germinate to give rise to the two kinds of prothallus, and the fertilised egg-cells grow into new plants.

Pillwort (*Pilularia*) [195] grows in the same kind of places as the last-named plant, and is a European species occurring in Britain. It possesses a creeping stem with roots, and narrow leaves. Parts of their bases are modified into rounded, brown spore-fruits, the shape of which has suggested the popular and scientific names. These contain a number of spore-cases of both kinds, which are liberated by the swelling up of mucilage, that bursts open the fruit in a valvular fashion. The rest of the life-history is much the same as in marsilia.

PRELIMINARY TREATMENT OF WOOL

Wool Sorting: its Theory and Practice. The Processes of Steeping, Scouring, Drying, Teasing, Opening, Burring, Oiling, and Blending

By W. S. MURPHY

Wool in the Store. Wool comes to the factory in bales weighing about 400 lb., and containing from 70 to 90 fleeces, according to the size and weight of the single fleece. We expect to find 70 or more fleeces in a Saxony bale, about an equal number in an Australian, and 80 to 90 in a Cheviot bale. We have reviewed the broad field of wool supply and noted the numerous varieties of wool; but in each one of those varieties another division must be made. One sheep, in the course of its existence, can produce four distinct classes of wool. These classes are: (1) Lamb wool; (2) yearling, or hogget; (3) ewe, or wether; (4) skin, or pelt. For lamb wool the lambs are shorn at the end of the season in which they have been born; hogget or yearling is taken off the year after; wether wool is obtained from the sheep in the years following; pelt wool is derived from the skin of the dead sheep. Class 1 is finest but short; class 2 is the best crop, being long and almost as fine as lamb; class 3 is the medium quality; class 4 is wholly inferior, the wool being in all stages of growth.

Theory of Wool Sorting. Before undertaking to deal with the fleece, we must clearly define our intention. Wool sorting is one of the few skilled handicrafts left in the factory. The sorter's work can never be done by any machine, because every sheep grows on its back qualities of wool differing very much, and those qualities are separable only by the skilled observer. From a single fleece fine sorters are required to pick out as many as fourteen different qualities of wool. It will be obvious that close observation, a quick eye, and deft hands are needed for the work.

Old-fashioned factories still retain the technical names for the various sorts now distinguished by numbers, woollen and worsted workers having their own special terms. The terms of the woollen sorts are: *Picklock* (fore shoulder), choicest in fineness of fibre, elasticity, and strength of staple; *Prime* (middle of body), only slightly inferior; *Choice* (back), true, but not so fine in fibre as prime; *Super* (loin), not so valuable as choice, but similar in general properties; *Head*, inferior sorts of wool derived from that part of the sheep; *Downrights*, derived from the lower sides; *Seconds*, from the throat and breast; *Abb*, the skirtings and edgings of the fleece; *Breech*, short, coarse hair from the hinder parts.

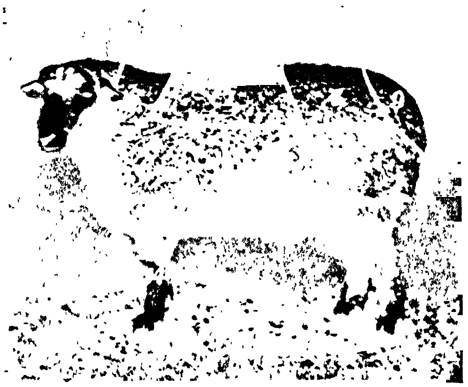
Worsted men have this classification: *Blue*, from the neck; *Fine*, from the shoulders; *Neat*, from the middle of the sides and back; *Brown-drawing*, from the haunches; *Britch*, from the tail and hind legs; *Cow-tail*, when the breech is very strong; *Brokes*, from the belly and lower part of the front legs, classed as *super*, *middle*, and *common*, according to quality.

The theory on which sorting is based involves an important assertion, founded on experience. Our assertion is that wool taken from the same place in fleeces of the same quality will be found equal in every respect for practical purposes. The value of that idea can hardly be estimated. We can get only a small quantity of wool of one quality from one fleece. Even if a whole fleece were of one quality, a single fleece does not make a web of cloth, and fleeces differ greatly. By adopting this principle, we get a number of uniform qualities of wool from each fleece, and the same qualities from an endless number of fleeces of the same kind.

34. WOOL SORTING (ENGLISH FLEECE)

Scientific Sorting. With such a wide range of material upon which to work, the sorter has not the power to obtain complete uniformity of treatment; but the trade has adopted two modes of classification which fairly cover all practical needs. The one method is generally used for British breeds, and the other for Merinos and similar kinds. Let us take the stronger class first [**34**].

1. *Shoulder.* Long and fine wool, growing close and even.
2. *Side.* Stronger, but otherwise equally good.
3. *Neck.* Short, but fine, liable to be mixed with greyish wool.
4. *Back of neck.* Inferior.
5. *Top of fore shoulder.* Faulty and irregular, but of medium quality.
6. *Loins and back.* Rather coarse and short, but fairly true in character.



35. WOOL SORTING (MERINO FLEECE)

7. *Middle of haunch.* Long strong wool of large staple

8. *Hinder parts.* Coarse and long, apt to be hairy.

9. *Top of hind leg.* Very like 7, but rather dirtier.

10. *Under body.* Short, dirty, but fine towards the fore legs—known as " brokes."

11. *Top of fore leg.* Short and fine.

12. *Throat.* Irregular, short, and kempy.

13. *Head.* Short, rough and coarse wool.

14. *Shanks.* Rough, hard wool, of little value.

The division of the Merino fleece has been best described by Dr. Bowman, and, with a few modifications, we adopt his scheme [**35**].

1 and 2. *Shoulders and sides.* The wools grown on these parts are remarkable for length and strength of staple, softness of feel, and uniformity of character. They are usually the choicest wools found in the fleece.

3. *Lower part of back.* This is also a wool of good, sound quality, resembling in staple that obtained from the shoulders and sides, but not so soft and fine in fibre.

4. *Loin and back.* The staple here is comparatively shorter, and the hair not so fine, but the wool on the whole is of a true character. In some cases, however, it is rather tender.

5. *Upper parts of legs.* Wool from these parts is of a moderate length, but coarse in fibre, and possesses a disposition to hang in loose, open locks. It is generally sound, but liable to contain vegetable matter.

6. *Upper portion of neck.* The staple of the wool clipped from this part of the neck is wholly of an inferior quality, being faulty and irregular in growth, as well as full of thorns, twigs, and other matters.

7. *Central part of back.* This wool closely resembles that obtained from the loins and back, and is rather tender.

8. *Belly.* This is the wool found on the under parts of the sheep, between the fore and hind legs. It is short, dirty, and poor in quality, and somewhat tender.

9. *Root of tail.* Fibre coarse, short, and glossy, and very often the wool is mixed with kemps or hairs.

10. *Lower parts of legs.* Most of this wool is dirty and greasy, the staple lacking curliness and the fibre fineness. It is usually full of burrs and vegetable matter.

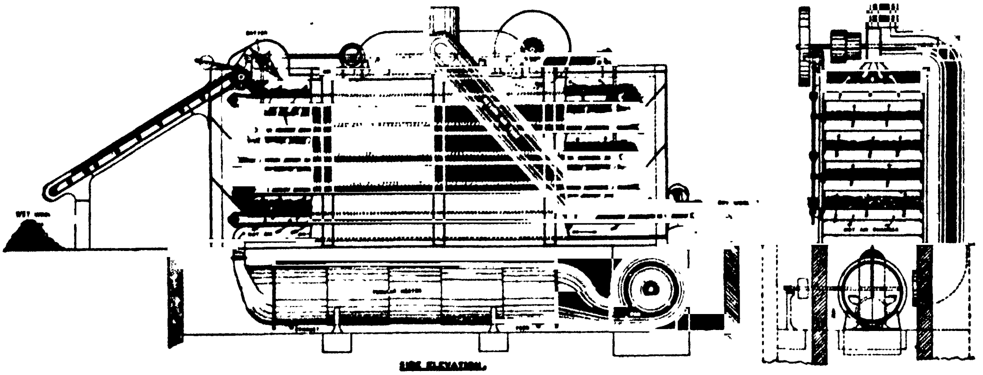
11, 12, 13. *Head, throat, and chest.* The wools from these parts are generally classed together, as having the same characteristics. A small portion of fair wool may often be got from the chest. The fibre as a whole is stiff, straight, and coarse, mixed with fodder, and kempy.

14. *Shins.* This wool is short, straight, and stiff, and of little value.

Practical Sorting. When unpacked from the bale, the wool is full of all kinds of dust and dirt. The best kind of sorting bench is made of a wooden frame enclosing a table of

36. WOOL SCOURING

woven wire, the smooth surface of which gives an even base to the fleece, while the meshes let through the dust and rubbish, which is drawn away by exhaust fans, through a wide tube, to the dust-pit. Lift the fleece flat, and lay it wool side undermost on the bench. Set the wool baskets round, those for the highest qualities nearest to the hand. Now take the big clipping shears, and remove adhering skin, tar-marks, rough edges, clogs, and other excrescences; then shear the fleece into two halves. Lay the half, wool side up, across the bench, head and tail, and sort out the various qualities, following the one table or the other, according to the kind or quality of fleece. In gripping, see that you take the wool away clean, because in some parts the quality of wool very suddenly alters from low to high, and mixing is fatal.



87. WHITELEY'S DRYING APPARATUS

Wool Steeping. High-class fleeces, such as Saxony and fine Botany, may be sent direct to the scouring machines; but we are engaged chiefly on stuff that is not first-class. All wools of average quality are usually very dirty, and the wool manufacturer is prudent who makes provision for steeping his wools before scouring. Steeping is a very simple operation, the object being to take away the rough dirt and to soften the matted staples. Various methods of steeping have been adopted, the simplest being a bath with a perforated double bottom, with wide meshes, which let the dirt fall through to the bottom of the bath and retain the wool. When the wool has been steeped long enough, and the water let off, it is roughly dried by being passed between a pair of rollers The best steeping arrangement we have seen is highly ingenious, and so contrived that the water penetrates the mass of wool from below, and maintains a circulating motion. These machines are easily managed, and require no detailed instructions.

Wool Scouring. This is one of the most important operations in the preparation of wool, and calls for detailed attention. Many a blemish has appeared in yarn which remained a mystery till the explanation was found in the scouring troughs. Two facts must always be kept in mind by the wool scourer—first, that a detergent acts chemically, for the most part; and, secondly, that wet wool felts and knots very readily. Simple as these facts appear, they have not been acted on by many would-be inventors of scouring machines. Taking a model from the domestic washing-tub, it has seemed to them a splendid thing to produce a scourer that would make a lot of splash and soapy suds, not knowing that wool splashed about gathers into knots and strings no man can unravel. The aim of the scourer is to permeate the wool with an effective detergent, with as little movement as may be possible. He must, of course, use a machine, and we should find one which will economise scouring ingredients, take the wool through comparatively free and open, let away the dirt readily, and deliver a clean wool at the end.

A good many scouring machines have been invented, but the model most generally used [86] is a combination of forks or pikes working the wool through a series of troughs filled with scouring liquor. Let us suppose that we have a scouring machine 60 ft. long and over 6 ft. broad, divided into three troughs by movable compartments, in which are perforated false bottoms 6 in. above the real bottoms. Hung horizontally across the troughs are rows of long forks, automatically moved by gearing in the sides of the machine, and between each trough a lifting and squeezing apparatus for transferring the wool from one trough to the other. This machine will do fairly good work, but it must have the proper ingredients to work with.

Scouring Liquors. Water is the vehicle of our detergent, but the detergent itself may be potash, carbonate of soda, silicate of soda, ammonia, or soap. Carbonate of soda gives a harsh feel to the wool; silicate demands a good deal of careful sousing, to clear out the hard silicate; and ammonia is very nice, but rather weak for most wools. We advise the following: First trough, 6 gallons potash soap mixed with pearlash; second, three gallons potash soap and pearlash in small proportion; third, pure, warm water. For coarse wools the water should be of a heat ranging from 90° F. to 130° F.; for finer wools, from 120° F. to 142° F. The gradation is from strong liquor to pure water. As the strong liquor trough receives the wool first, it must become foul first, and it has been found a profitable plan to empty the strong liquor out when it has become too dirty, run the second trough into the first, and the third trough into the second, make up the first and second to the required strength, and fill the third again with pure water. This method economises potash, water, and labour.

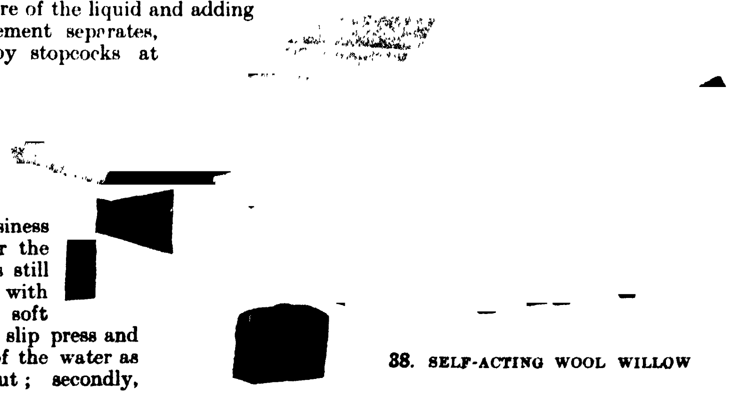
Scourer at Work. Having got the machine into working order, we put the wool on a feed-lattice that bears it forward into the strong scouring liquor, and there it is waved gently to and fro, while being brought along inch by inch—the liquor sapping through it meanwhile—to the end of the trough. Here the wool is automatically lifted on to a board, and drawn between two heavily clothed rollers, which gently press out the superfluous liquor, and drop it into the second trough. Ingeniously devised buckets, like elevators, catch the squeezed liquor and lift it back into the first trough. Through trough number two the wool makes the same slow and steady progress, and then is plunged into the warm-water trough, in which it is gently soused free from cleansing liquor, to be firmly squeezed in the drying rollers. Thence the wool must be taken to the drying apparatus.

Utilising Waste Scour Liquors. Analysis of raw wool shows that one-third of the weight of raw wool is made up of yolk and grease. In the scouring process this substance falls to the bottom of the scouring-trough, and impregnates the scouring liquid. When emptying the trough, we simply pour the whole lot—waste liquor and residuum—into large settling tanks. From the first settling tank, in which the hard dirt drops away, the liquor is pumped up into the highest of a series of settling tanks. Here the liquid is scoured by the addition of sulphuric acid, and heated by the injection of steam. The acid separates the grease from the soda, and three distinct layers form in the tank—the grease on the top, the water and suspended acid and soda, and a mixture of earthy matters and grease at the bottom. From the surface the grease is skimmed off, and the rest of the contents run down into the tank below, where the process is repeated. Here, however, we make an effort to recover our scouring acid, and succeed by raising the temperature of the liquid and adding more acid. Each element separates, and is drawn off by stopcocks at different levels in the side of the tank. The recovered potash can again be utilised in the troughs

Having got the grease, our next business is to make it fit for the market, because it is still dirty and mixed with water. First, the soft masses are run into a slip press and freed from as much of the water as can be squeezed out; secondly, the grease is transferred to the hot press, in which, under steam, the oily substance is melted out, and escapes into a tank, where it is taken possession of by the purifiers, who ladle it up into a lead-lined vessel, search it thoroughly with strong sulphuric acid for remaining traces of water, and then barrel it for sale under the name of "Yorkshire grease." In all this we exhibit the principle only of utilising the liquors; the methods are various.

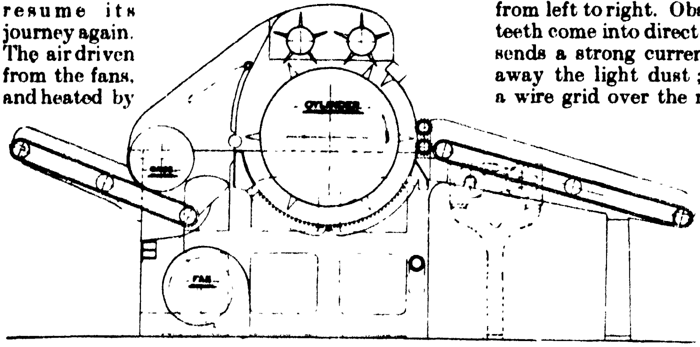
Drying Wool. Before wool can be taken a step further it must be thoroughly dried; all our machinery presupposes a perfectly dry material. Two drying machines are commonly used, though some factories have drying rooms specially fitted up on principles almost as varied as the number of them permits. The older machine is a roof-like wire frame, within the triangle of which are two sets of fans on revolving spindles, and two pairs of hot steam pipes. In the apex of the roof are two funnels. On the wire sides of the frame the wet wool is laid in an even layer. Steam is sent into the pipes, and the fans set revolving. As they revolve the fans cause the air to circulate down through the funnels, round the hot pipes, and up through the wool. Theoretically, it seems all right; but in practice the machine has defects, especially in work requiring speed and uniformity. For one thing, the lower fibres get an undue share of both heat and air

A West of England man named Moore, experiencing the defects of the machine described, invented the newer one. It is a highly ingenious contrivance, though rather elaborate. Picture a large box, with doors at each end and two funnels from the top leading out to the roof, and there crowned by exhaust fans. Such is the external aspect of this dryer. Having our wet wool ready, we open the fore-end door, and see inside a long row of rollers revolving transversely between a double series of steam pipes, one series above and the other below, and above the higher range of pipes another row of revolving rollers. At the far end, its spiked rims almost touching the whole structure, turns a huge wheel.



38. SELF-ACTING WOOL WILLOW

We feed in the wool, and it travels like a fluffy snake along the lower row of rollers, to be dragged off and cast up on to the row of rollers above by the swiftly running wheel. The action of the top rollers brings the wool back along the length of the machine, and it drops down at the near end to resume its journey again. The air driven from the fans, and heated by the steam pipes, makes a warm draught of air go through the travelling wool. Sufficiently dry, the wool must now be freed from the circle. For this purpose, the door at the back of the machine is opened, and the flinging action of the wheel throws the wool outwards on to the floor. The batch of wool may weigh 100 lb., and the time taken is about 20 minutes. The side elevation and cross-section of a new and improved model of this machine, made by Messrs. Whiteley & Sons, Limited, of Lockwood, are shown in 37.



39. SECTION OF WOOL WILLOW

Teasing Wool. The clinging properties of wool are very convenient in making threads; but we find these very qualities rather troublesome in the raw wool. Crinkled and serrated, the fibres hold together in tufts, and no amount of scouring can effect a separation. But parted they must be, or we can make no yarn. Each fibre, indeed, should be singled out and put into its place. When it is considered that 4,000 fibres of fine merino wool can grow on a square inch of skin, the intricacy of the mixing may be imagined. For picking out and separating the combined fibres we have a long series of machines, graduating from a simple tearing apart to the detailed direction of the individual fibres toward their places in the long filaments we name yarn.

Opener. Our first wool-teaser is called the *opener*, and it resembles closely a machine of the same name used in the cotton factory, although the two are distinct and call for separate description. Several makers have put forward new and, in some cases, improved openers, but after we have learned to work the ordinary machine, the others will present no difficulty. The working part of the opener [38] is hidden under its strong iron casing, but we must look under the iron [39]. In the centre is a large cylinder, and above it two small cylinders. Along the large cylinder iron bands are fixed, and from each band spring two rows of curved teeth. On the little cylinders we see long iron spikes set like formidable teeth in the jaw of a terrible monster. By giving the wheels a turn we can observe how these things work. The motion of the large cylinder is quicker than that of the small ones, and the movement of the former is from right to left, while the latter turn from left to right. Observe, also, that none of the teeth come into direct contact. A fan at the back sends a strong current of air through, drawing away the light dust; beneath the cylinders is a wire grid over the receptacle for refuse. The creeper band in front completes the machine.

Lattice Creeper. Before going further, let us explain the feeding contrivance constantly used in many textile machines, and often referred to, but seldom described. If you lace a number of flat strips of wood together so that they form a band, join the ends, and stretch over two rollers, you have what we call an endless lattice band or creeper. Obviously, if the rollers revolve, the band will move forward, and anything placed upon it must also be borne in the same direction. This is the feeding apparatus on most textile machinery.

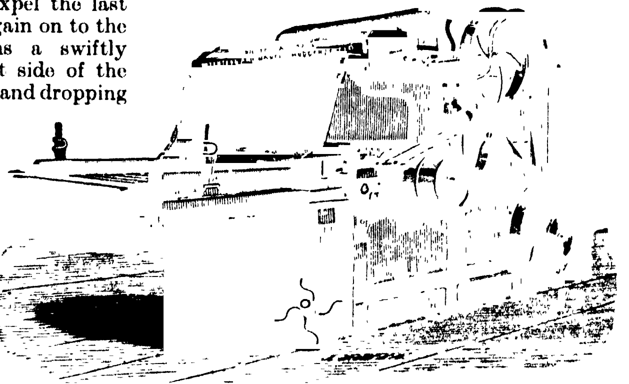
Opener at Work. Pile the dried wool on the lattice creeper, and set the machine going. As the wool comes through the fluted feed-rollers, the curved teeth of the cylinder bear it away; but the little cylinders slowly turn above, and pick the wool out of the teeth of their big neighbour with their long spikes. As the large cylinder travels at ten times the speed of the small ones the pull between them is very great; yet, because the one set of teeth does not enter the plane of the other, there is no positive drag, the cylinders parting, as it were, the tufts between them in an amicable spirit of division. Thus the tangled locks of wool are opened out, and at the same time, by the beating, dragging, and whirling, combined with the blowing of the fan, the dust yet adhering to the fibres is driven out.

Burring. Fed among grass and quick-seeding plants of various kinds, sheep gather in their coats an incredible quantity of those clinging, prickly seeds described comprehensively as burrs. Scouring and opening do not clear the wool of these things, and many of us have been seriously puzzled to discover what would. Leave but a few fragments of those insidious little seeds in, and they will appear in the finished cloth as a surprising multitude of pins, almost invisible, but horribly sharp. Two methods are adopted, and both are admittedly imperfect, for opposite reasons. One is what is called the extract method, in which sulphuric acid is used to destroy all vegetable matters; it is effective, but the texture of the wool is deteriorated. The other method is mechanical, by means of the burring machine

[40], and this is admittedly defective in that it does not infallibly clear out all the fragments of seeds, but it has the merit of preserving the quality of the wool and forwarding the manufacturing process. When we deal with the utilisation of waste, the chemical method of treating wools for burrs will be detailed at length. At present we proceed with the mechanical method, which is in the direct line of our advance in preparing the fibres.

Burring Machine. If any machine was ever devised with strict attention to the end in view, it is the burring machine. Every part of the contrivance is directed to two purposes, one to disentangle the fibres, and the other to throw up the burrs so that they can be cleared off easily. On this account alone it is worthy of detailed study. In front there is the usual feed-lattice, which carries the wool forward to the two fluted feed-rollers, and beyond, quite inside the machine, is the licker-in, or revolving fan. The latter merely beats the wool down on a travelling lattice-sheet within the machine, which carries it onward to where a roller-brush is running, and this swiftly revolving brush lifts the fibre on to the central cylinder armed with needle-pointed steel plates, presenting serried rows of small teeth. Borne swiftly round on the central cylinder, the fibres come in contact with the two spiral-bladed burr rollers and the ledger blades, which, acting and reacting, open out the wool and draw off the burrs. Thence the loosened fibres are taken by a large roller and beaten firmly against a grid, to expel the last few clinging particles, and let off again on to the large cylinder, behind which runs a swiftly driven brush, always keeping that side of the cylinder clear, cleaning off the wool, and dropping it into the box at the end of the machine.

Blending. The wool is now ready for blending. We saw at the sorting bench how a single fleece yields fourteen different qualities of wool. By supposition, however, all this batch of wool we have been treating has been taken from one sorting number—say, Number 1, Botany, or Australian merino. This makes our task of blending a comparatively easy, but by no means a superfluous, operation. Select and breed your sheep ever so carefully, each sheep will have its own individuality and peculiarities. Superficially regarded, the members of a flock of sheep appear very much alike; but if you watch a shepherd at work, you will be astonished to discover that he knows nearly every individual sheep. Careful examination of the wool before us will enforce the same lesson. Though belonging to the same class, those wools differ in a marked degree, and no ingenuity of selection can alter the fact. It is a well-known fact that by combining differences an average is produced. That is the object of blending.



40. BURRING MACHINE

At this point, however, some words of explanation are necessary. If there were no such entities as money and markets, our procedure would be unchallenged. If every kind and class of wool were used unmixed to produce the yarn and class and kind of fabric for which it is best suited by nature, textile manufacture would be a much easier profession than it is. There are many blends, which may be roughly classed under these heads: (1) Different wools; (2) wool and silk; (3) wool and cotton; (4) wool and bast fibres, such as flax, hemp, and jute; (5) wool and waste fibres, such as noils, shoddy, mungo, and extract.

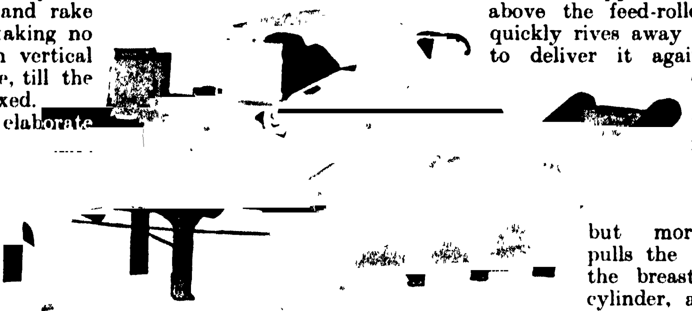
Mixed Wools. The main reason for mixing wools is the compulsion put upon manufacturers to produce given counts of yarn at low prices. The fluctuations of the raw wool market largely affect the wool-blender's work. When New Zealand wool was selling at 4¾d., in 1895, the temptation to mix in lower class wools was small; but when the average price rose to over 8d., the position became wholly different On that side it is impossible to be definite; every season brings its own peculiar problems. But in regard to the wools themselves clear rules must be observed. In our table of wools we have given the highest counts of yarn into which the various wools can be spun. The finest of fine Leicester cannot be spun to a higher count than 70, and most manufacturers consider 50 as high as should be attempted. To mix that wool in for a higher count of yarn is to fail. The safe rule is to blend nearly related wools of similar character—soft with nearly soft, fine with fine medium, carding with carding, and combing with combing wools

Wool and Silk. Before being brought to the blending-room the silk waste should be thoroughly prepared. It is perhaps most important to see that the length of the silk fibres does not too greatly exceed that of the wool staple. Next to that is the question of colour, the silk, in the case of mixed colours, always making part of the ground or main body.

Wool and Cotton. For a long time theoretic difficulties were constantly being raised to this mixture, while actual practice showed good results Coarse wools cannot combine with cotton, because there is not in cotton a corresponding weight or thickness of fibre. Very fine, short wools, such as the best merino, mix well with cotton. Equal quantities of both fibres produce the best results, and the blending should be very intimate.

Practical Blending. Wool blending is a hand process, for the most part. The wool is spread out on the floor in thin layers, one layer above the other, till the whole batch stands a square mass. The wider the differences in the mixture, the thinner should be the layers, so that the mixing may be more intimate. Now take a fine rake and rake down the stack, taking no more than a thin vertical slice at each stroke, till the whole has been mixed.

Other and more elaborate methods are often adopted; but, as we have broadly hinted, these relate to blends and theories of blending far beyond the scope of our study.



41. COCKSPUR TEASER, WITH OILING APPARATUS

Oiling. When scouring the wool, we deliberately took from it the natural oil or grease, and now it is so bare and harsh that we cannot make much use of it. In the machines used up to this point the fibre has been treated gently, tearing and severe dragging being particularly avoided. But wool cannot be formed or made into yarn by such soft persuasions. We must put it through the scribbler, at least, whose myriad teeth will drag and pull with vicious insistence. Those scaly serrations, upon which so much of the value of the fibre depends, must, left bare, be broken and torn. Olive-oil is the best and, we believe, finally the cheapest lubricant for wool.

Oil Spraying and Teasing. The "Fearnought" [41] is worthy of special note, because it is the first and simplest of that class of machines named carders, with which we shall have a great deal to do. By carefully observing this contrivance we prepare ourselves for understanding the more complex carding machines. In main structure the "Fearnought" consists of an iron frame supporting a feed-lattice, a central cylinder, a series of small rollers revolving over the cylinder, and a fan cylinder at the end. Let us examine the relations and character of these.

On the surface of the large cylinder spikes, shaped like dog's teeth, form diamond squares about an inch in area, and similar teeth are on the small rollers, while two rows of straight teeth stick out from the edges of the wings of the cylindrical fan Note now the rollers: they alternate large and small, the large being called workers and the small the strippers. All the workers are geared together, and a separate gearing connects the strippers, the latter being required to revolve much more quickly than the former, for reasons we shall understand presently. Over the fore-end of the machine is the oiling apparatus, with oil cistern and spraying distributor, efficiently controlled from the machine.

Lay the blended wool on the feed apron. As it moves slowly forward in a thin layer, the spray of oil passes over it like a softening vapour, and the wool is drawn in by the feed-rollers, the lower one of which faithfully presents the fibres to the large cylinder, while the upper one, like a greedy agent, wraps a portion of the stuff round itself But a stripper roller is geared above the feed-roller, and it quickly rives away the spoil, to deliver it again to the cylinder. Another worker roller, revolving in the same direction, but more slowly, pulls the wool from the breast of the cylinder, and winds it round itself. Once again a stripper ally of the big, spiky wheel interferes, digs its long teeth into the teeth of the worker, and, being driven at greater speed, pulls away the wool and swiftly surrenders it to the cylinder. Thrice the triple action is repeated, worker, stripper, and cylinder drawing and teasing out the wool and at the same time making the mixing more intimate.

Meanwhile the fan is doing its double work, driving with its swiftly flying blades all the remaining dust out of the fibres, and at the same time doffing the teased wool from the cylinders with the straight teeth fixed on the edges of its flanges or wings, and throwing it into the receptacle.

Three principles are at work here, and can be more easily viewed in this simple machine than in any other. First, there is the principle of directly opposed force, which is probably the first movement in mechanical effort. All hand tools are simple examples of the principle. But instead of acting as one of the opposing forces, the wool manufacturer gets three sets of power-driven rollers to do it for him. The second principle is differential motion, by which bodies moving in the same direction at different speeds react upon each other or on the agent between them, such as the wool in the present instance. The third principle is that of centrifugal force, the magnetic power developed by the revolving bodies causing the wool to cling and remain within the little round prescribed.

INTEREST

120. If a person borrows money, he usually pays something for the loan. The sum of money he borrows is called the *Principal;* the money he pays for the use of the principal is called *Interest.* Interest is generally reckoned at so much for the use of each £100 for one year. This amount is called the *Rate per Cent. per Annum.*

Thus, if we say that £200 is borrowed for three years at 4 per cent. per annum, we mean that the borrower, at the end of each year, pays the lender £4 for each £100 borrowed—*i.e.*, £8 interest for each year.

In the above example, where the interest is supposed to be paid to the lender at the end of each year, it is clear that the interest is proportional to the number of years—that is, the interest for two years is twice the interest for one year, the interest for seven years is seven times that for one year, the interest for one month is $\frac{1}{12}$ that for one year, and so on. Interest thus reckoned is called *Simple Interest.*

If, however, the interest at the end of the first year is unpaid, it is added to the principal and thus forms a new principal for the second year. Consequently, the interest for this second year will be more than the interest for the first year. When the interest is added, year by year, to the principal, as it becomes due, the money is said to be lent at *Compound Interest.*

The sum obtained by adding the interest for any given time to the principal is called the *Amount* in that time.

121. Suppose we have to find the simple interest on £420 for three years at 5 per cent. per annum. We can obtain the result by means of "compound proportion."

(i.) We are required to find *interest.* Hence, £5, the *interest* on £100 for one year, will be the third term of the proportion.

(ii.) We next ask, "If the interest on £100 is £5, will the interest on £420 be more or less?"—whence we obtain the ratio £100 : £420.

(iii.) "If the interest for one year is £5, will the interest for three years be more or less?"—giving the ratio 1 year : 3 years.

Thus, the statement is:

$$\left.\begin{array}{l}£100 : £420\\ 1\text{ yr.} : 3\text{ yr.}\end{array}\right\} :: £5 : \text{Required Interest.}$$

$$\therefore\ \text{Interest} = \frac{£5\times420\times3}{100}.$$

Hence, we see that

$$\text{Interest} = \frac{\text{Principal}\times\text{rate}\times\text{time (in years)}}{100},$$

or, in other words, ***to find the simple interest multiply the principal by the time expressed in years, and by the rate per cent., and divide the product by*** 100.

Example 1. Find the Simple Interest on £162 10s. for four years at $3\frac{1}{2}$ per cent.

$$\text{Interest} = \frac{£162\frac{1}{2}\times4\times3\frac{1}{2}}{100}.$$

$$= \frac{\overset{13}{\cancel{325}}\times\cancel{4}\times7}{\cancel{2}\times\cancel{2}\times\underset{4}{\cancel{100}}} = £\frac{91}{4} = \underline{£22\ 15s.\ \textit{Ans.}}$$

Sometimes it is more convenient to arrange the work as follows:

Example 2. Find the amount of £345 15s. 4d. in 15 months at $2\frac{1}{2}$ per cent. Simple Interest.

£	s.	d.
4)345	15	4
86	8	10
2)432	4	2
		2
864	8	4
216	2	1
£10,80	10	5
20		
16,10s.		
12		
1,25d.		
4		
1,00f.		

EXPLANATION. 15 months = $1\frac{1}{4}$ years. Write down the principal, and add one-quarter of it, giving £432 4s. 2d. Multiply this result by $2\frac{1}{2}$, giving £1,080 10s. 5d. Divide by 100 [Art. **25**]. Thus, the interest is £10 16s. $1\frac{1}{4}$d., and Amount = Interest + Principal.

	£	s.	d.
∴ Interest =	10	16	$1\frac{1}{4}$
Principal	345	15	4
∴ Amount =	£356	11	$5\frac{1}{4}$ *Ans.*

122. Since, Interest = Principal × Rate × Time ÷ 100, it follows that if we are given any three of the four quantities—interest, principal, rate, time—we can find the fourth quantity. In the last article we considered the case in which interest was the quantity to be found. We shall now work examples illustrating the other three cases—*viz.*, to find the rate, to find the time, and to find the principal.

Example 1. At what rate per cent. will the Interest on £175 for 4 years amount to £24 10s.?

Either, by proportion, find the interest on £100 for 1 year (which is the required rate), knowing that the interest on £175 for 4 years is £24 10s. Thus

$$\left.\begin{array}{l}£175 : £100\\ 4\text{ yr.} : 1\text{ yr.}\end{array}\right\} :: £24\ 10s. : \text{Required Rate.}$$

$$\therefore\ \frac{\overset{7}{\cancel{49}}\times\overset{4}{\cancel{100}}}{2\times\underset{7}{\cancel{175}}\times\cancel{4}} = \underline{3\tfrac{1}{2}\%\ \textit{Ans.}}$$

Or, find the interest on £175 for 4 years at 1 per cent. and divide the result into the given interest. Thus—

Interest on £175 for 4 years at 1 per cent.

$$= \frac{175 \times 4}{100} = £7.$$

$$\therefore \text{ Required rate} = \frac{£24\tfrac{1}{2}}{£7} = \underline{3\tfrac{1}{2}\% \ \textit{Ans.}}$$

Note. If we are given the *amount* instead of the *interest*, we must first find the interest by subtracting the principal from the amount and then proceed as above.

Example 2. In how many years will £175 amount to £199 10s. at 3½ per cent.?

Here, interest = £199 10s. − £175 = £24 10s.

We now find the interest on £175 for 1 year at 3½ per cent. and divide the result into the given interest.

Interest on £175 for 1 year at 3½ per cent.

$$= \frac{£175 \times 3\tfrac{1}{2}}{100} = \frac{7 \times 7}{2 \times 4} = £\tfrac{49}{8}.$$

$\therefore$ Required number of years

$$= £24\tfrac{1}{2} \div £\tfrac{49}{8},$$

$$= \frac{49}{2} \times \frac{8}{49} = \underline{4 \text{ years} \ \textit{Ans.}}$$

Example 3. Find the Principal which will amount to £199 10s. in 4 years at 3½ per cent.

The interest on £100 for 4 years at 3½ per cent. = 4 × 3½ = £14.

$\therefore$ £100 is the principal, which amounts to £114 in 4 years at 3½ per cent.

Hence we have the following proportion :

£114 : £199 10s. :: £100 : Required Principal.

$$\therefore \text{ Required Principal} = \frac{£100 \times 199\tfrac{1}{2}}{114}.$$

$$= \frac{\overset{25}{\cancel{100}} \times \overset{7}{\cancel{399}}}{\cancel{2} \times \underset{2}{\cancel{114}}} = \underline{£175 \ \textit{Ans.}}$$

If we are given the interest, instead of the amount, we proceed in the same way—*i.e.*, we find that the interest on £100 for 4 years at 3½ per cent. is £14, and then we know that £14 : Given Int. :: £100 : Reqd. Principal.

123. If the time, for which the interest is required, is from one given date to another, such as "April 12th to July 14th," we do not count the first of these days. In the case just mentioned, interest would be reckoned for 30 − 12, *i.e.*, 18 days of April, 31 of May, 30 of June, and 14 of July, making a total of 93 days.

124. Compound Interest. From what has already been said about Compound Interest it is plain that we find the Amount in any given time by calculating the Simple Interest for each year in succession, the Principal, of course, becoming greater in each succeeding year. The Compound Interest for the whole period will be the difference between the Amount and the original Principal.

The work can be more compactly arranged by using £'s and decimals of a £, than by using £ s. d.

Example. Find the Compound Interest on £1375 for 2 years at 3 per cent.

$$\begin{array}{r l}
£1375 & = \text{1st year's Principal.} \\
41{\cdot}25 & = \quad ,, \quad \text{Interest.} \\
\hline
1416{\cdot}25 & = \text{2nd year's Principal.} \\
42{\cdot}4875 & = \quad ,, \quad \text{Interest.} \\
\hline
1458{\cdot}7375 & = \text{Amount.} \\
1375 & \\
\hline
£83{\cdot}7375 & = \text{Total} \\
20 & \\
\hline
14{\cdot}7500\text{s.} & \\
12 & \\
\hline
9{\cdot}000\text{d.} & \\
\end{array}$$

$$\underline{£83 \ 14\text{s.} \ 9\text{d.} \ \textit{Ans.}}$$

Explanation. To find the interest for 1 year at 3 per cent. we multiply £1375 by 3 and divide by 100. Hence our second line is obtained by multiplying 1375 by 3 and moving the digits two places to the right. Then, adding 41·25 to 1375, we get £1416·25 for the second year's principal. We now repeat the process—*i.e.*, multiply 1416·25 by 3 and move the digits of the product two places to the right. This gives 42·4875 for the second year's interest. Add this to the second year's principal, and we obtain the Amount. Subtract the original principal, and we have £83·7375 for the Compound Interest. The £·7375 is reduced to shillings and pence, as in Art. **91**, Ex. **3**.

125. Before proceeding further, it will be convenient to consider how the labour of finding Compound Interest may be lessened.

Suppose we have some decimal, such as 5·27463, and that we are asked to write it "correct to three places." This means that we are to write down a number of only three decimal places which shall be as near as possible to the actual value 5·27463. The result is 5·275. For the given decimal is 5·2746... and 46 is nearer to 50 than to 40, so that 5·275 is nearer the true value than is 5·274.

Similarly, the value correct to two places is 5·27.

Again, our smallest coin is the farthing. Hence it is unnecessary, in commerce, to express any sum of money more accurately than "to the nearest farthing"—*i.e.*, we take a value which differs from the true value by no more than half a farthing. Now, 1 farthing = £$\tfrac{1}{960}$ = £·001041... which is very nearly equal to £·001. Thus, if we have a sum of money expressed as a decimal of a £, correct to three places, it will be correct to the nearest farthing. Therefore, in working Compound Interest, if we reject figures beyond the fifth decimal place we shall still obtain the value correct to three places—*i.e.*, to the nearest farthing.

Example. Find the amount at Compound Interest of £38 2s. 6d. in 3 years at 2½ per cent.

$$\begin{array}{r r l}
 & £38 \ \ 2\text{s.} \ \ 6\text{d.} & \\
= & £38{\cdot}125 & = \text{1st year's Principal.} \\
 & 2{\cdot}5 & \\
\hline
 & {\cdot}76250 & \\
 & {\cdot}19060 & \\
\hline
 & {\cdot}95310 & = \text{1st year's Interest.} \\
 & 38{\cdot}125 & \\
\hline
 & 39{\cdot}07810 & = \text{2nd year's Principal.} \\
\end{array}$$

39·07810 = 2nd year's Principal.
2·5
·78156
·19535
·97691 = 2nd year's Interest.
39·07810
40·05501 = 3rd year's Principal.
2·5
·80110
·20025
1·00135 = 3rd year's Interest.
40·05501
£41·05636 = Amount.
20
1·12720s.
12
1·52640d.
4
2·10560 far.
£41 1s. 1½d. *Ans.*

Explanation. Multiply by 2 and move the digits two places to the right, as in Art. **124**. Next, in multiplying by ·5, the first figure of £38·125 which gives a digit in the *fifth* place is the 2. Hence we begin multiplying at the 2, exactly as if the multiplicand only consisted of 38·12. Similarly, in finding the second year's interest, the first digit of 39·07810 which, when multiplied by 2, gives a digit in the fifth place is the 8; and when multiplying by ·5 the first digit required is the 7. Proceeding in this way, we obtain £41·05636, of which not more than the 41·056 will be correct, but this, as we have seen, gives a result correct to a farthing. If we work out the above example in full, we find that the Amount is £41·056455078125. This, when reduced to £ s. d., gives £41 1s. 1½d. + ·196875 farthings; *i.e.*, £41 1s. 1½d., which agrees with the first result. Evidently then, it is a mere waste of labour to work the example in full.

126. In some cases we are told that the interest is payable half-yearly, or quarterly. We proceed in the same way as before, except that we find the interest for a *half* year (or quarter year), and add the principal, to obtain the principal for the second half year (or quarter year), and so on, until we reach the end of the required time.

127. As in Simple Interest, if we are given the Amount (or the Interest), the Rate per Cent., and the Time, we can find the Principal.

First, find the Amount (or the Interest) of £1 for the given time at the given rate. Then we have the proportion:

Amount (or Interest) of £1 : Given Amount (or Interest) :: £1 : Required Principal.

Thus, the principal is found by dividing the given amount (or interest) by the amount (or interest) of £1.

128. Present Worth and Discount. Suppose a man has borrowed £100 at 4 per cent., payable after one year. His debt at the end of the year will be £104. Suppose, also, that he finds himself in a position to discharge the debt at the end of six months, instead of letting it go on for the full year. Clearly, instead of paying £104, he should only pay such a sum as, put out to interest at 4 per cent., will amount to £104 in the remaining six months. By the method of Art. **122**, **Ex. 3**, such a sum is found to be £101$\frac{49}{51}$, or £101 19s. 3d., nearly.

This £101 19s. 3d. is called the *Present Worth* of the £104 due in six months at 4 per cent. The difference between the present worth, £101 19s. 3d., and the amount which would be due in the six months, £104, is called the *True Discount.*

Thus, the problem of finding the Present Worth is exactly the same as that in Art. **122**, **Ex. 3**, when the interest is simple; and is the same as Art. **127** if the interest is compound.

Example **1**. Find the Present Worth, and True Discount, on £40 8s. due in 73 days at 5 per cent.

Interest on £100 for 73 days at 5 per cent. = $\frac{1}{5} \times 5$ = £1.

∴ Present worth of £101 = £100.

Hence £101 : £40 8s. :: £100 : Reqd. P. W.

$$\left.\begin{array}{l} \therefore \text{ Reqd. Present Worth} = £\frac{100 \times 40\frac{2}{5}}{101} = £40 \\ \therefore \text{ True Discount} = £40\ 8s. - £40 = 8s. \end{array}\right\} \textit{Ans.}$$

Example **2**. Find the Present Worth of £1458 14s. 9d. due in 2 years at 3 per cent. Compound Interest.

£1.
·03
1·03 = Amount in 1 year.
·0309
1·0609 = Amount in 2 years.

∴ Present Worth of £1·0609 = £1.

∴ Present Worth of £1458 14s. 9d.

£1458·7375
£1·0609
1·0609)14587375(£1375 *Ans.*
39783
79567
53045

Explanation. Find the amount at 3 per cent. compound interest of £1 for 2 years, *viz.*, £1·0609. Reduce 14s. 9d. to the decimal of £1. Then, since £1 is the Present Worth of £1·0609, the required Present Worth is the quotient of 1458·7375 by 1·0609.

COMMERCIAL OR BANKER'S DISCOUNT. BILLS OF EXCHANGE

129. In commercial transactions, an agreement to pay a sum of money at some stated future date is made by a *Bill of Exchange*, or by a *Promissory Note.*

Suppose a merchant, James Brown, receives an order for goods to the value of £200, from another merchant, John Smith. Instead of paying cash, Smith authorises Brown to draw a Bill, to be paid by Smith after a certain period, usually three months. Brown accordingly writes out the Bill of Exchange, as follows:

Birmingham,
13th November, 1905.
£200.
Three months after date, pay myself, or order, the sum of two hundred pounds, value received.
James Brown.
To
Mr. John Smith,
Merchant,
Leeds.

The document must bear a stamp, the amount of which varies with the amount of the bill. In this case it would be 2s.

The bill is forwarded to Mr. Smith, who "accepts" it—*i.e.*, acknowledges the debt, by writing "Accepted," followed by his signature, across the face of the bill, and returns it to Mr. Brown. The bill is nominally due in three months after November 13th, but the law allows three extra days, called *Days of Grace*; so that it legally falls due, or "matures," on February 16th.

Brown may keep the bill till February 16th and then "present" it for payment, to Smith, or Smith's banker, who will pay the £200.

If, however, Brown is in want of ready money before February 16th, he may sell the bill to a third person, either a banker or a *Bill-broker*, for cash. The broker is then said to have *discounted* the bill. Since the broker has still to wait a certain time before Smith pays the bill, he will not pay Brown £200 for it. Suppose Brown gets the bill discounted on December 5th "at 5 per cent." Then, the number of days before the bill falls due is 26 + 31 + 16 = 73 days. The broker, therefore, calculates the interest on £200 for 73 days at 5 per cent., and deducts that amount (£2) from the *Face Value* (£200) of the bill. He thus pays Brown £198 for the bill.

The amount which the broker deducts from the face value is called *Commercial*, or *Banker's, Discount*. We see, then, that the problem of finding the Banker's Discount is the same as that of finding the Simple Interest on the face value, for a given time, at a given rate (Art. 121).

130. The ordinary form of Promissory Note is as follows:

Leeds,
13th November, 1905.
Three months after date I promise to pay to Mr. James Brown, or order, the sum of £200, value received.
John Smith.

It should be noticed that in the case of a Bill of Exchange the document is written by the creditor, while a promissory note is written by the debtor.

131. Since,

Amount (*i.e.*, Face Value) = Present Worth + True Discount, it follows that

Interest on Face Value = Interest on Present Worth + Interest on True Discount; that is,

Banker's Discount = True Discount + Interest on True Discount.

The difference between the Banker's Discount and the True Discount is, therefore, the interest on the True Discount.

Example. The difference between the Banker's and the True Discount on a certain bill due in 2 years at 5 per cent. simple interest is £1 13s. Find the Amount of the bill.

We know that £1 13s. is the simple interest on the True Discount for 2 years at 5 per cent.

Therefore, by the method of Art. 122, Ex. 3, we can find the true discount. For £10 is the interest on £100 for 2 years at 5 per cent. Hence,

£10 : £1 13s. :: £100 : True Discount.

$$\therefore \text{ True discount} = £\frac{100 \times 33}{200} = £16 \text{ 10s.}$$

The Banker's Discount is, therefore, £16 10s. + £1 13s. = £18 3s., and we have now only to find on what principal the interest for 2 years at 5 per cent. amounts to £18 3s.

∴ £10 : £18 3s. :: £100 : Required Bill.

$$\therefore \text{ Amount of Bill} = £\frac{100 \times 363}{200} = \underline{\underline{£181 \text{ 10s. } \textit{Ans.}}}$$

EXAMPLES 16

1. Find, to the nearest penny, the Simple Interest on £2523 11s. 6d. for 5 years at 3½ per cent.

2. At what rate per cent. Simple Interest, will £875 amount to £980 in 3 years?

3. The simple interest on a certain sum for 8 years at 4½ per cent. is £183 3s. Find the Sum.

4. In what time will money double itself at 4 per cent. Simple Interest?

5. Find, to the nearest penny, the Amount of £1420 in 3 years at 6 per cent. Compound Interest.

6. Find, to the nearest penny, the Compound Interest on £58 4s. 7d. for 2 years at 4 per cent., the interest being payable half-yearly.

7. Find the Present Worth of £231 1s. 10½d. due in 2½ years at 3½ per cent. simple interest.

8. Find the True Discount on £1447 0s. 7½d. due in 3 years at 5 per cent. Compound Interest.

9. A bill due in 3 years is discounted at 4 per cent. The difference between the True Discount and the Commercial Discount is 10 guineas. Find the Amount of the bill.

10. A bill of £400 drawn on December 4th at 8 months is discounted by a banker on March 14th, the rate of discount being 5 per cent. How much will the holder of the bill receive?

Answers to Arithmetic

EXAMPLES 14

1. The second man's stride is 32 in. Since his stride is longer than that of the first man, he will take fewer steps in going the same distance. Hence, 32 : 30 :: 3120 steps : Ans.

$$\therefore \text{ Reqd. number of steps} = \frac{3120 \times 30}{32} = \underline{\underline{2925 \textit{ Ans.}}}$$

2. When the reinforcement arrives there are provisions for 137 − 50 = 87 days. The number of men is now 5000 + 800 = 5800. Hence, 5800 : 5000 :: 87 days : Required time.

$\therefore$ Required time $= \dfrac{87 \times 5000}{5800} = \underline{75 \text{ days } \textit{Ans.}}$

3. After 36 days there are $48 - 36 = 12$ days left, in which time the same amount of work has to be done as was done by 20 men in 36 days. The number of men required to do this is found from the proportion 12 : 36 :: 20 men : Required Number. Whence, Required Number of men = 60. The contractor must, therefore, engage $60 - 20 =$ 40 extra men *Ans.*

4. Candles at 8 to the lb. will burn a shorter time than those at 6 to the lb. Hence 8 : 6 :: 6 hours : Ans. Which gives Required Time $= 4\frac{1}{2}$ hours *Ans.*

5. $\frac{2}{5}$ of the women are unmarried, *i.e.*, $24 = \frac{2}{5}$ of the women. $\therefore$ Total number of women $= \frac{5}{2}$ of $24 = 60$. Now, number of men : number of women :: 3 : 4. Hence, number of men $= \frac{3}{4}$ of $60 = 45$. But 5 men in every 9 are married. $\therefore$ Number of married men $= \frac{5}{9}$ of $45 = 25$ *Ans.*

6. At first $\frac{3}{8}$ of the cask is water. At the finish $\frac{3}{8}$ of the cask is wine. Therefore, when 16 gallons of the mixture was taken out, it left as much wine as there was water to begin with. But 16 gallons of the mixture contains $\frac{5}{8}$ of 16 gallons = 10 gallons of wine. Hence. there were 10 gallons more wine than water to begin with. Now 8 gallons of mixture contains 5 wine and 3 water, *i.e.*, there are 2 gallons more wine than water in every 8 gallons of mixture. Therefore, there are 10 gallons more wine than water in $5 \times 8 = 40$ gallons of mixture. The cask, therefore, held 40 gallons *Ans.*

7. Statement is

$$\left.\begin{array}{r}5 : 72 \\ \pounds 2\ 5\text{s.} : 2\text{s. } 6\text{d.}\end{array}\right\} :: 15 \text{ miles : Ans.}$$

Whence, *Ans.* = 12 miles.

8. 4 men do as much as 8 women. $\therefore$ 1 man = 2 women. Hence, 2 men and 3 women = 7 women. We then have the statement

$$\left.\begin{array}{ll}7 \text{ women} & : 8 \text{ women} \\ 5 \text{ ac.} & : 8 \text{ ac.} \\ 12 \text{ hr.} & : 10 \text{ hr.}\end{array}\right\} :: 3\tfrac{1}{2} \text{ days : Ans.}$$

Whence, *Ans.* $= 5\frac{1}{3}$ days.

9. Calling the boys A, B, C, D, we have

A's 4 pages = B's 5 pages
B's 6 ,, = C's 7 ,,
C's 3 ,, = D's 2 ,,
Reqd. D's = A's 18 ,,

Hence,

$$\textit{Ans.} = \frac{5 \times 7 \times 2 \times 18}{4 \times 6 \times 3} = \underline{17\tfrac{1}{2} \text{ pages.}}$$

10. As in Art. **112**, Ex. **2**, we have

A's 100 = B's 99
B's 120 = C's $118\frac{3}{4}$
Reqd. C's = A's 1760

Therefore, while A goes 1 mile, C goes

$$\frac{99 \times 118\frac{3}{4} \times 1760}{100 \times 120} \text{ yd.} = 1724\tfrac{1}{4} \text{ yd.}$$

Therefore, A beats C by $1760 - 1724\frac{1}{4} = 35\frac{3}{4}$ yd. *Ans.*

11. The *values* are as 2 : 3 : 4, which is the same thing as £2 : £3 : £4. Now £2 = 16 half-crowns, £3 = 30 florins, £4 = 80 shillings. Therefore, the *numbers* of the coins are as 16 : 30 : 80. We have, then, to divide 126 coins proportionately to 16, 30, 80. But $16 + 30 + 80 = 126$. Hence, the heap contains 80 shillings *Ans.*

12. The statement is

$$\left.\begin{array}{rll}55 & \text{yd.} & : 120 \text{ yd.} \\ 20 & \text{ft.} & : \ \ 25 \text{ ft.} \\ 5 & \text{ft.} & : \ \ \ 4 \text{ ft.} \\ 12 & \text{hr.} & : \ \ 11 \text{ hr.} \\ 5 & \text{days} & : \ \ \ 4 \text{ days}\end{array}\right\} :: 100 \text{ men : Ans.}$$

Whence, 160 men *Ans.*

EXAMPLES 15

1. To lose 5 per cent, he must sell for 95 per cent. of cost. To gain 7 per cent., he must sell for 107 per cent. of cost. $\therefore$ 95 : 107 :: £247 : Required Price. Hence, he must sell for $247 \times 107 \div 95 =$ £278 4s. *Ans.*

2. He buys *equal* numbers at the two rates, and sells 5 for 3d. Take, then, the L.C.M. of 2, 3, and 5, *i.e.*, 30. Now 30 at 2 a 1d. cost 15d., and 30 at 3 for 2d. cost 20d. The total cost is 35d. He sells the whole 60 at 5 for 3d., *i.e.*, for 36d. He thus gains 1d. on an outlay of 35d. His gain % is $\frac{1}{35}$ of $100 = 2\frac{6}{7}$ *Ans.*

3. 9s. 7d. – 9s. 2d., *i.e.*, 5d., is 4 per cent. of the cost, or $\frac{1}{25}$ of the cost. $\therefore$ Cost $= 25 \times 5$d. = 125d. Hence, by selling at 9s. 7d., he loses 10d. His loss per cent. is $\frac{10}{125}$ of 100 = 8 per cent. And, therefore, by selling at 9s. 2d. he loses $8 + 4 = 12$ per cent.

4. 750 eggs at 15 a shilling cost $750 \div 15 = 50$s. He loses 2 per cent. of this, *i.e.*, he loses 1s. But the number of eggs he lost was 13. Hence, he sold 13 eggs for 1s.

5. 24 lb. of tea at 1s. 10d. cost £2 4s.; 8 lb. at 2s. 10d. cost £1 2s. 8d. The total cost of 32 lb. of tea is, therefore, £3 6s. 8d. To gain 10 per cent. he must sell the 32 lb. for $\frac{110}{100}$ of £3 6s. 8d. Hence, the selling price per lb.

$$= \frac{11 \times \pounds 3\ 6\text{s. } 8\text{d.}}{10 \times 32} = \underline{2\text{s. } 3\tfrac{1}{2}\text{d. } \textit{Ans.}}$$

6. As in Art. **119**, Ex. **5**, if he buys 5 per cent. cheaper and sells to gain 4 per cent. he sells for $\frac{95}{100} \times \frac{104}{100}$ of actual cost $= \frac{247}{250}$ of actual cost. But he really sells to gain 10 per cent., *i.e.*, for $\frac{11}{10}$ of cost. Therefore, £168 is $(\frac{11}{10} - \frac{247}{250})$ of cost. Whence, cost = £1500, so that to gain 10 per cent. he must sell for £1650 *Ans.*

7. Marked price = 20 per cent. above cost $= \frac{6}{5}$ of cost. Selling price $= \dfrac{92\frac{1}{2}}{100}$ of marked price $= \frac{37}{40}$ of $\frac{6}{5}$ of cost $= \frac{111}{100}$ of cost. $\therefore$ He gains 11 per cent.

8. He sells one house for $\frac{11}{10}$ of cost. $\therefore$ Cost $= \frac{10}{11}$ of £990 = £900. He sells the other for $\frac{9}{10}$ of cost. $\therefore$ Cost $= \frac{10}{9}$ of £990 = £1100. $\therefore$ He bought the two for £2000, and sold them for £1980. $\therefore$ He loses £20.

OUTLINES OF EDUCATIONAL TOURS ABROAD

A Brief Guide to all Places of Interest in the Leading Towns of Spain and Portugal. Where to Go and What to See

By J. A. HAMMERTON and WILLIAM DURBAN, B.A.

SPAIN

What traveller would willingly miss the land of the hidalgo, of the Cid, of Don Quixote, of the noblest age of the Mauresque civilisation, of fairy-like architecture, of pristine chivalry, of glorious sunshine, and of semi-tropical fruitfulness? Fallen from its mediæval greatness though it is, Spain fully retains the gorgeous colouring of its unique romance, and its multitudinous and varied attractions of scenery, architecture, archæology, and popular custom offer endless interest to the visitor. Spain has been comparatively neglected by English tourists, but during the last few years the tide of patronage has set steadily in this direction. It is easy to acquire a sufficient knowledge of the beautiful and sonorous Castilian language for the purpose of a visit, and the country lies within easy access of our shores, whether overland through France or by direct sea passage. The people are among the most courteous on earth, and are abundantly solicitous of the comfort of those who wish to make any sojourn among them.

The traveller in the ordinary way reaches Biarritz by way of Paris, and from Biarritz proceeds over the Pyrenees to Burgos.

A Week in Spain. So short a stay will be fully occupied by visiting Madrid, Toledo, and Cadiz, these being the best points to select for so brief a period. The tourist who cannot afford a longer holiday will gain a gratifying glimpse of the country and the people, and will learn something of the national spirit.

A Fortnight in Spain. Even this is all too short, but it will be filled with enjoyment, and will afford opportunities of visiting a number of the most famous cities.

FIRST DAY. Few places are more interesting than BURGOS, a wonderfully beautiful old-time city, the birthplace of Spain's national champion, the Cid. The magnificent *Cathedral*, in certain respects unrivalled in the world. Its fourteen chapels. Each of these is in reality a fine church. The crucero, or lantern, is the gem of the whole structure. Philip II. said it was built by angels rather than men. The transept, full of marvellously delicate sculpture. The beautiful High Altar. The splendid choir, in two tiers, with walnut stalls. The *Town Hall*, in which is the body of the Cid. The *Castle*, where the Cid was married. Carriage drive to the famous Monasteries of *Las Huelgas* and *Miraflores*.

SECOND DAY. That marvellous edifice, 25 miles N.W. of Madrid, *El Escorial*, is reckoned by Spaniards as the eighth wonder of the world. It has been aptly described as "a mountain of granite shaped into a palace, a church, a convent, and a mausoleum." It is the leviathan of architecture. It is the mammoth tomb of the kings and queens of Spain, is constructed of solid granite, was erected by Philip in commemoration of the Battle of St. Quentin, and took twenty years in building. The *Panteon*, or Royal family tomb. All of marble and jasper. Sixty bodies of Royalties lie here. The *Convent*. Many pictures and statues. The rich and beautiful *Library*. The splendid *Palace*, with its magnificent towers. The grand *Church*, with sumptuous chapels and altars, and the richest reliquary in Spain.

THIRD DAY. The most elevated of all European capitals is MADRID. The first day to be spent in a survey of the many beautiful, spacious squares, all finely adorned with trees, and of the wide streets and interesting shops. It is a city of flowers. The fruit markets are marvellous at the right season. The *Plaza Mayor* and *Plaza del Oriente* are centres of the busiest and most fascinating life.

FOURTH DAY. The second day at Madrid. The *Museo*. Here is that picture gallery which is the envy of every other city in Europe. A collection of splendid gems of pictorial art. No fewer than forty-six Murillos, including the world-famed "Conception"; sixty-four Velasquezes, including the great equestrian portrait of Philip IV.; ten Raphaels, including the "Holy Family," called "La Perla," because Philip IV., on beholding it, exclaimed, "This is the pearl of my pictures"; with numerous works of Titian, Ribera, Teniers, Van Dyck, Tintoretto, Veronese, Claude, etc., etc. The *Royal Armoury* contains an unrivalled collection of weapons of all ages, together with the armed effigies of kings, emperors, and generals in suits of armour the most resplendent ever manufactured.

FIFTH DAY. A third day would be spent at Madrid. The *Royal Palace*, one of the grandest in Europe. The Grand Patio, or Square, and the thirty saloons, magnificently furnished, on the first floor. The beautiful garden. The *Church of San Francisco*, with historic tombs and curious pictures. The *Church of Atocha*, with venerated miraculous images.

SIXTH DAY. TOLEDO is grandly situated on a high rock by the Tagus, which almost circumvents the city. The whole town is a museum of the majestic and romantic past, specially rich in Mauresque edifices. The wonderful *Cathedral*, the finest in Spain next to that of Seville. The famous façade, with relievo of the Last Supper, containing sixty full-sized statues. The portals are also celebrated for their exquisite ornamentation in stone. The noble tower, 329 ft. high. The five naves, the 750 stained windows, the Royal tombs, the chapels round the church, and the lovely cloisters, all make a memorable spectacle. The beautiful Gothic pile known as the *Church of San Juan de los Reyes*. The famous *Alcazar of Charles V.*, an immense ruin of golden red colour.

SEVENTH DAY. A city of which any nation might be proud is SEVILLE, the delight of every visitor, beautifully situated on the banks of the Guadalquivir, full of wonderful architectural relics of the Moorish period. The famous *Cathedral*, one of the most sublime ecclesiastical creations in the world. Its Giralda Tower is a gem of Saracenic construction, of loveliest rose tint. The stained windows, ninety-three in number. The Court of Oranges. The nine doors of entrance to the Cathedral are sumptuous portals. The pavement of black and white marble cost £30,000. Seven naves of imposing perspective and immense height. The enchanting view from the summit of the Giralda.

Eighth Day. Two days are necessary to give any idea of Seville. The glorious *Alcazar*, or House of Cæsar, an ancient Moorish palace. Matchless internal decoration in arabesques. This is, next to the Alhambra at Granada, the most precious and perfect Moorish monument in Spain. The loveliest portion is the Patio, with marble pavement, fountain, and trefoiled arcades, which are considered marvels of grace and lightness. The palace called the *Casa de Pilatus*, belonging to the Duke of Medina Celi, built as an imitation of the house of Pontius Pilate at Jerusalem. It contains a noble Patio. The *Golden Tower* on the bank of the river ; formerly a fortress. Delightful hours are to be spent in surveying the streets and squares of this fascinating city. The famous Tobacco Factory, with thousands of girls at work, should be seen.

Ninth Day. Reach Cadiz. The Biblical Tarshish. One of the world's most venerable cities, yet a delightful modern town full of fascination for the visitor. On a peninsula, joined only by a narrow causeway to the mainland. A place of brilliant colour, with shining white walls, long rows of elegant houses, glass and gilt balconied miradores. The granite ramparts and spacious terraces afford delightful promenades. *La Vieja*, or Old Cathedral, with thirteen chapels. The *Cathedral of Santa Cruz*, or New Cathedral, imposing in style, and richly ornamented with precious marbles and jasper. *Los Capuchinos*, an old convent, with renowned picture gallery containing gems of art, including Murillo's last work, the famous "Marriage of St. Catherine." The shops of Cadiz are specially attractive, for the city is famous for fans, ladies' shoes, gloves, and guitars.

Tenth Day. Gibraltar. The *Lower Fortifications*, the *Rock Galleries*, the *Signal Tower*, the *Cave of St. Michael*, and the *Alameda*, or fashionable and charming promenade, called the "Pride of Gibraltar," laid out in English style, abounding in geraniums and bowers, and commanding exquisite views of the Straits and the African coast. The town has quaint and curious winding, narrow streets.

Eleventh Day. We come now to Granada. The wonder-city of Spain. A place of fountains and rippling streams, situated on one of the loveliest plains in the world. It stands on four hills, divided somewhat like a pomegranate, and rises to the height of 2,245 ft. above the sea-level. The snow-clad mountains of the Sierra Nevada range adorn the prospect. The city extends in an amphitheatre round the river bank, and is crowned by the incomparable *Alhambra*, the supreme gem of Moorish architecture. The gardens and woods round this building are exquisitely beautiful, and are the haunt of countless nightingales. The Hall of Ambassadors, the Court of Lions, the Lion Fountain, and the various other halls, courts, corridors, apartments, and fountains make up a bewildering scene of indescribable enchantment. The noble *Cathedral*, with five naves, dome of white and gold inside, the fine marble pavement, and lovely chapels. *La Cartuja*, a famous monastery and church, just outside the town, with magnificent frescoes.

Twelfth Day. Cordova. Exquisitely situated on the Guadalquivir. Famous for its superb *Cathedral*, formerly a grandiose mosque. The most perfect specimen extant, or ever erected, of Moorish architecture. The beautiful Patio, called the Court of Oranges. The Hall of Thousand Pillars, forming nineteen spacious naves. The unrivalled mosaics.

Thirteenth Day. Barcelona. The fine *Cathedral*, the *Rambla Promenade*, and the *Bull-ring*.

Fourteenth Day. Back to Madrid.

Travel and Food. Railway travelling in Spain is now perfectly comfortable, and hotel accommodation in the cities is greatly improved. The food is excellent. Bull beef is the staple meat. Fruit is abundant and unsurpassed. Grapes, oranges, melons are of the most magnificent varieties. Eggs fried in oil or mashed with tomatoes are everywhere offered. Water is scarce. Beggars are numerous and insolent. The amusements are the universal guitar-playing, the wonderful dancing of both sexes, and the brutal bull-fights.

If the tourist wishes to spend three weeks or a month in Spain he may make extensions to Cartagena, Pampeluna, Zaragossa, Boadilla, Malaga, La Roda, Utrere, Irun, Xeres, Algecir, etc.

Expense. The cost of a circular trip such as we have described above, occupying a fortnight, should not be more for steamer and railway tickets than £25 first class, or £20 second class. About 12s. a day should be reckoned for hotel expenses and extras.

Treatises on travel in Spain are very numerous, and afford delightful and useful reading for the intending tourist. We may commend Mrs. Ramsay's "Summer in Spain," Pemberton's "Winter Tour," Rose's "Among Spanish People," Workman's "Awheel in Iberia," Jacacci's "On the Trail of Don Quixote," Lawson's "Spain of To-day," Hare's "Wanderings," Lomas's "Sketches," Hay's "Castilian Days," Elliott's "Idle Woman in Spain," Robert's "Autumn Tour in Spain," Thornbury's "Life in Spain," Gadow's "In Northern Spain," Wood's "Romance of Spain," McClintock's "Holidays in Spain," St. Barbe's "In Modern Spain," Gallenga's "Iberian Remains," Luffman's "Vagabond in Spain," Main's "Cities and Sights of Spain," Crocket's "An Adventurer in Spain," and Bart Kennedy's "A Tramp in Spain."

PORTUGAL

It may almost be reckoned that Portugal as a holiday region for British tourists has been "discovered" by King Edward through his visits in recent years. Comparatively few in this country were formerly aware how lovely is the western section of the Iberian Peninsula. It is a land of fruit and flowers all through the year. Here the orange and the lemon, the almond and the walnut, the olive and the loquat, the prune and the cherry, the peach and the grape reach their highest perfection. The humblest cottages are embowered in roses, and flowers that are nursed as exotics in northern climes are in Portugal as plentiful as weeds. This delightful little country is the California of Europe. The celebrated harbour of Lisbon is acknowledged by Americans to surpass the Golden Gate of San Francisco. The people are a self-respecting, interesting race, proud of their home and contented with it.

Portugal is so easily accessible that it is almost as convenient to visit as France, Holland, or Belgium. Of course, the direct route is by sea to Lisbon, which is the natural door into the country.

A Week in Portugal. This is sufficient for a survey of Lisbon, Cintra, Belem, and Oporto. The majority of visitors confine their attention to these points, and either pass on to Madrid or proceed round the Peninsula to the Mediterranean.

A Fortnight in Portugal. Two weeks allow opportunity for a glorious round in one of the world's historic districts, full of the most romantic associations, and of the utmost beauty.

First Day. Lisbon is a marvellous capital for a tiny nation, and is built on seven hills, in terraces rising one above the other. The Tagus is here broad and majestic. The city is said to have been founded by Ulysses, and originally called Ulyssipi. Grand squares, with fine trees, lovely flowers, and marble fountains. The most curious of these open spaces is the *Prazo dom Pedro*, nicknamed "Rolling Wave Square" from the fantastic arrangement of its tesselated pavement. The beautiful Garden of *St. Pedro di Alcantara.*

Second Day. The *Cathedral* at Lisbon is an ancient and massive Gothic edifice, which withstood the great earthquake, the Chapel of St. Vincent being one of Lisbon's chief ecclesiastical ornaments. The *Church of St. Roque*, with the famous Chapel of St. John the Baptist. The decorations of this chapel are wonderfully elaborate, being encrusted with mosaics of Italian masters, lapis lazuli, and costly marbles ornamented with gold and amethysts. The *Estrella Church*, a beautiful miniature of St. Peter's at Rome. The prospect from its dome is magnificent.

Third Day. Four days may be devoted to Lisbon. On the third visit the *Gallery of Fine Arts*, the *Museum*, the *Pant eon*, the *Artillery Museum*—all these institutions contain fine old collections of national relics from the days of Portuguese greatness. The *Aqueduct*, a splendid engineering construction bringing water from springs nine miles distant.

Fourth Day. Still at Lisbon, the fourth day would be given to visiting Belem, a famous and beautiful suburb of Lisbon, named after the wonderful *Hieronymite Church* in its midst, founded by Vasco di Gama as a thank-offering after his safe return from the East Indies. The cloisters are of the utmost beauty. Here are the tombs of Di Gama, Camoens, and Catherine of Braganza. The *Royal Palaces* of Lisbon—the Necessidades and the Ajuda. The splendid Gothic monasteries of *Batalha* and *Alcobaca*, in the suburbs of the capital.

Fifth Day. Visit Cintra. Byron termed this famous *Castle* "a blessed Eden," and Southey described it as "the most blessed spot in the habitable world." Situated on a grand rock, it was once the Alhambra of the Moorish kings. *Chapel*, with lovely transparent alabaster work. The *Castle of Montserrat*, on another peak near by, with exquisite gardens.

Sixth Day. Across the wide Tagus is Setubal, an important port. Grand harbour; fine quays: five massive forts. The environs are crowded with beautiful groves of orange, lemon, and olive trees. The place is full of natural charm.

Seventh Day. Evora. This city is generally considered the most beautifully situated in the whole country, and it is one of the most interesting. The ruins of the walls and forts are astonishing. In the immense *Gothic Cathedral* are fine pictures by Gran Vasco; also a famous *Library*.

Eighth Day. Faro. A beautiful and wealthy episcopal city, famous for historic associations and for its splendid old *Moorish walls*. In the noble bay are three charming islands.. Lovely environs, thickly planted with orange and fig trees and splendid cork oaks. Great fisheries.

Ninth Day. Spend this at Beja. Wonderful *fortifications*, with forty towers; massive old *Castle*; fine *Cathedral*. Extensive leather and earthenware factories. A characteristic Portuguese town.

Tenth Day. Coimbra, on the Mondego, is by many reckoned the most interesting city in the land. The town stands on a conical hill in a superb situation. Its aspect from every side is exceedingly beautiful, and the whole city is picturesque and attractive. The neighbourhood abounds in charming scenery, and is fascinating for excursionists. At least two days should be spent here.

Eleventh Day. During the second day in this old Gothic city further details are to be studied. The fine *Aqueduct* of twenty-one arches. Portugal's only *University* is here. Attached to it is the lovely *Botanic Garden*. The noble *Cathedral*. The handsome churches of *Santa Clara* and *Santa Cruz*.

Twelfth Day. Oporto. Portugal's great commercial emporium. Its buildings, erected in tier after tier, present a magnificent picture. The remnants of the ancient walls. The fine business streets are intensely interesting. The *Rua Nova dos Inglezes* is a splendid thoroughfare. The *Rua Nova de S. Joao*, with lofty houses and gaily painted and gilt balconies.

Thirteenth Day. Second day in Oporto. Walk in the various grand squares, for which Oporto is famous. The grandest is the *Praca de S. Ovidu*, on a hill, giving a magnificent sea view. The *English Factory House*, of white granite, with beautiful façade. The *Convent da Serra*, perched on a high rock. The fine old *Cathedral*. The *Torre de Clerigos*, the highest tower in the country.

Fourteenth Day. Back to Lisbon.

Travel and Food. Travel in Portugal is constantly interesting. The courteous, frugal, and industrious inhabitants have a fascination of their own. The atmosphere, laden with Atlantic ozone. is uniformly bracing. The enchanting climate, the radiant sunshine, the brilliant moonlight nights, and the semi-tropical vegetation impress the visitor with a sense of indefinable charm. The bullfights, so repulsive in Spain, are mild and harmless here. It is a land of domestic comfort. Every description of food is exceedingly cheap, and rent is lower, perhaps, than anywhere else in Europe. Europe has no finer market than that of Lisbon. The meat is much better than in Spain, and the fish is unrivalled. Nowhere on the Continent can fruit and vegetables be obtained in greater abundance or of superior quality. Thus Portugal is peculiarly enjoyable as a pleasure resort.

Fares. The sea passage to Oporto or Lisbon from Liverpool costs £6 first class single. The boats of the Booth Company run weekly. There are no second or third class tickets, though these may be obtained from Havre, and there is no reduction for return ticket.

Books. Those who purpose visiting Portugal should previously read some of the following works: Lady Jackson's "Fair Lusitania," Leck's "Iberian Sketches," Smith's "Spring Tour," Latouche's "Travels in Portugal," Shore's "Three Pleasant Springs in Portugal." and O. Crawfurd's "Round the Calendar in Portugal."

THE RISE OF THE ROMAN EMPIRE

The Building of Rome. Its Early Rulers. Election of Consuls. The Patricians and the Plebeians. Rome under the Oligarchy

By JUSTIN McCARTHY

THE history of Rome belongs to a much later period of the world's development than that of Egypt or of Greece. The whole Italian peninsula appears to have attracted the attention of colonists from foreign States at a much later date than many other parts of Europe, which would seem to us after a glance at the map to be much more difficult of access than the Italian regions. But Italy, barricaded on all her northern frontier by lofty mountains, showed also too long a stretch of harbourless coast on either side to tempt the enterprise of the small and imperfectly constructed vessels which such early traders as the Phœnicians could send out in those remote ages.

Early History. The Roman States did not, even at a time when Rome was approaching the zenith of her greatness, spread over the whole of the Italian peninsula. Of the tribes which originally occupied the greater part of Italy, the Latins, the Sabines, and the Etruscans were the most numerous, the most civilised, and the best adapted for development and progress. The Latins and the Sabines appear to have been alike populations of native growth, although during the course of their history we shall find that they proved as hostile to each other as any two foreign races brought together by invasion and thus settled in the same country. The Etruscans were a people of foreign descent, and continued to be in almost every sense foreigners while they held their place upon Italian soil. They constituted a powerful State while Rome was yet obscure, and if they could only have become united among themselves, they might have conquered the whole of that part of Italy in which Rome was to grow up.

They were a highly artistic people, and some of the best monuments which tell of Rome's early growth are described as bearing distinct evidence of Etruscan creation. The Italian language is declared to have been Etruscan at its best. The Etruscans loved the sea, and were at home there alike as commercial traders and as sea-rovers and pirates.

The Growth of a State. The earliest history of Rome is merely legendary or mythological. It is the only history we have, and it may perhaps be taken as representing, apart from its fabulous and impossible additions, the beginning and early growth of Rome into a State. Rome is said to have been founded by Romulus about 750 years before the Christian era. This much, at least, we may accept on the safe assumption that it is about as likely as anything else. Then we come to the legendary and the mythological. Romulus and Remus are described as the sons of Rhea Silvia and of Mars the war god. The mother of the children having been a vestal virgin, consecrated to a life of purity and celibacy, was condemned with her children to be drowned in the River Tiber The cradle in which the brothers were cast into the water was flung ashore by chance, and thrown near to the den of a she-wolf, who treated them as if they had been her own cubs, suckled them, and brought them up. Macaulay, in one of his "Lays of Ancient Rome," makes one of his figures apostrophise the Roman:

> "Thou that art sprung from the war-god's loins,
> And hast tugged at the she-wolf's breast."

The children are said to have been found by a shepherd, who carried them from the den to his own home, where they were brought up by his wife. When they grew up, conscious, no doubt, of their remarkable descent, they set out to found a city on the banks of the Tiber, and this enterprise proved fatal to one of them. Remus, according to some legends, quarrelled with his brother because Romulus insisted that the city should be called Roma, from his own name. Another story tells us that when the first wall of Rome had been built, Remus showed his contempt for the undertaking by leaping over the wall—that wall which was meant to be protection against all invasion—and thus aroused the anger of Romulus to such a degree that he killed Remus on the spot.

Building of Rome. Romulus continued his work as a city founder, and Rome was built —not in a day, but with patience and success; and he was accepted as the first sovereign of the new State. Rome soon became well peopled with men, but there were hardly any women within its walls. This obviously would never do. Here, again, we are given to assume that celestial inspiration came to the aid of Romulus, although it does not seem to have been the kind of inspiration which the ordinary mortal could expect from a celestial source. Romulus made proclamation that a splendid series of games and festivities was to be carried on in Rome, and invited the Latins and the Sabines, his near neighbours, to grace the sports by their presence.

The invited guests thronged to the new city in large numbers, and while the festival was going on the Roman youths, already instructed by their ruler, rushed in on the festal ground and carried off the young women. After long altercations, this extraordinary capture of their women led the Sabines to make war on Rome. A new marvel was then to occur. During a long and desperate battle between the Romans and the Sabines, the captured Sabine women, who seemed to have become meantime completely reconciled to their captors, rushed upon the field of battle, threw themselves between the opposing hosts, and implored their fathers and brothers to enter into terms of peace with their

Roman neighbours. To the modern reader it might seem as if the devotion of the Sabine women to their Roman captors could only increase the hatred of the Sabine fathers, brothers, and lovers for those new favourites of their womenkind. But the Sabine warriors magnanimously yielded to the prayer of the women; the two armies consented to sheath their weapons; the two peoples agreed upon terms of peace, and resolved to form themselves into one united State.

Rulers of Rome. For a time, Romulus and the Sabine king reigned together over the new State, and on the death of the Sabine sovereign, Romulus reigned alone for nearly forty years. According to legend, Romulus was taken from this world to the realms of immortality in a fiery chariot by his father Mars. He afterwards appeared as a spirit to a Roman friend, and bade that friend bear a message to the Roman people, ordering them to pay homage to Romulus as their guardian deity, and to give him the name of Quirinus. There is, indeed, another story, having less of the miraculous, which tells us that Romulus became an insufferable tyrant, and that the Roman senators, finding his rule intolerable, put him to death secretly, cut up his body into small portions, carried the portions home with them under their robes, and buried them in various places, the better to secure the secrecy of the deed. Then, it may have been, that some senator conceived the idea of the god Mars carrying the living Romulus up to heaven in a fiery chariot.

After the death of Romulus the story of Rome's development goes on to tell of six other kings of Rome. Numa Pompilius was the second, and his reign is said to have been one of absolute peace and prosperity, extending over a period of nearly forty years. Numa was followed by Tullus Hostilius, Ancus Martius, Tarquinius Priscus, and Servius Tullius. Servius Tullius, the sixth king, distinguished himself by endeavouring to establish something like an equalised constitution among Roman citizens. We are told that he was in favour of establishing a property qualification for citizenship rather than the qualification of birth and rank, and that by these proposed reforms he aroused the implacable hostility of some of the patrician order, and was assassinated by them, or at their instigation. He was succeeded by Tarquinius Superbus, the haughty and selfish monarch who was destined to be the last of the Roman kings. Tarquinius is described as having some qualities of statesmanship, as well as of conquest, and by wars and political and family alliances he made Rome the chief nation of the Latin races.

Tarquinius Superbus. He abolished many of the rights and privileges which had been conferred by his predecessor upon the Plebeians, for from the beginning of Roman history there had been that division of the people into two classes, the Patricians and the Plebeians. Some events which legend ascribes to the reign of Tarquinius Superbus—"Tarquinius the Proud"—have afforded subjects for poetry and the drama down to modern days. Sextus, the son of Tarquinius, was guilty of a shameful outrage upon Lucretia, the wife of his own cousin. When he had left her in her agony and shame, Lucretia sent for her husband and father, who came with some friends, and to them she told the story, implored them to avenge her wrong, and in their presence stabbed herself to the heart. One of those in that horrified group was Lucius Junius Brutus, a nephew of the reigning sovereign. That sovereign had already, in one of his bursts of suspicion and hatred, put to death the elder brother of Junius Brutus, and Junius, in order not to be regarded as dangerous to the sovereign, assumed the ways and manners of a harmless idiot. For that reason he received and adopted the added name of Brutus, which meant an idiotic personage, Junius being his family name, the name of an influential house among the higher Romans.

Junius now threw off his assumed deportment of idiocy, swore with all the others to avenge Lucretia's wrong, and put himself at the head of those who were determined on vengeance. Brutus summoned the Roman people together, told them the story, and called on them to punish the tyrant. The whole city took up the cause, and pronounced for the deposition of the King, and for his instant banishment from Rome. Tarquinius fled and took refuge in Etruria. Some of the neighbouring kings and States espoused his cause, and marched their armies against Rome. Brutus, in the meantime, had been elected one of the two first Consuls to whom the government of the State, now to be formed into a Republic, was to be committed.

Election of Consuls. These Consuls were to be supreme magistrates, having equal authority, and to be elected annually. The consular office appears and reappears at various times during succeeding ages of Roman history. Tarquinius had the assistance of Lars Porsena, the sovereign of Clusium, who proved a very powerful ally, and whose name has been made familiar to modern readers by many historians, poets, and dramatists. The famous battle of Lake Regillus decided the struggle in favour of the Romans. Tarquinius escaped and died miserably in exile.

A familiar story told of Brutus is that he ordered the execution of his own two sons because they were engaged in an attempt to restore Tarquinius, so absolute and unselfish was his devotion to the interests of his country. Lars Porsena proved so successful in his march against Rome that he was able to occupy a great hill outside the city, and would have entered the city itself by the bridge which connected the hill with Rome, but for the gallant defence made by Horatius Cocles. The story of that brave defence, whether it be a real event or a fabulous creation, has been told and re-told in many languages since the first consular days of Rome. Macaulay tells it over again in his "Lays of Ancient Rome," and reminds us how:

"With weeping and with laughter,
Oft is this story told:
How well Horatius kept the bridge
In the brave days of old."

THE SABINE WOMEN INTERVENING BETWEEN THE ROMANS AND SABINES

Photo Neurdein

Lars Porsena finally made peace with the Romans, and withdrew his forces. But the terms on which peace was made are variously stated. The Roman historians generally endeavour to make out that Porsena had no alternative but to make peace; but the general opinion, both of the ancient and of the modern world, is that Porsena, although he did not persist in striving to occupy the city, held it for a while at his mercy, and only withdrew his troops on condition that the Romans should pay him a yearly tribute as a practical evidence of submission to conquest.

Roman Characteristics. Up to this period the story of Rome has little or nothing in it which is absolutely authentic—little or nothing which can be established by any actual record—while many of its incidents and events are utterly and obviously fabulous. But we can get, even from the Roman story as we have it, a very clear idea of the general character and ways of the people it describes—the people who at one time believed in it. Modern discovery makes it certain that the foundation of a walled city on the Palatine Hill was unquestionably laid in some dim early period, which might well correspond with the creation of the city of Rome. We can learn from that story, fabulous or not, what were the characteristics which the early Romans admired and reverenced in their leaders and their heroes, in their wives and their children, and what were the qualities regarded as evil and dangerous to public and private welfare. We can see that the Romans loved and honoured courage, unselfishness, self-sacrifice, in men and women alike; that they honoured purity in women and filial devotion in children; that they admired literature, art, and knowledge; and, even while far too much given up to aggression and conquest, still regarded as among humanity's highest qualities a sincere desire for peace.

History and Tradition. The reports which reach us, in whatever form, may be taken to represent the general belief of the time, and thus far can be accepted as a contribution to history. We may assume that the general impression left on the mind of succeeding generations by those earlier princes must have represented in some degree their reigns and characters. Therefore, it is at least a reasonable assumption that tradition gives us in that sense a fair idea of the times, the great events, and the reigning sovereigns in Rome's earliest history. It is not probable that tradition represented a man who was a brutal tyrant as a wise, just, and beneficent sovereign, or that some man of high character who strove to make his subjects happy was a Tarquinius Superbus.

There is nothing improbable about the story of those early rulers as it has been handed down to the modern world, and, in absence of all evidence to the contrary, we may accept it as generally trustworthy.

We have already seen that in its earlier days the population of the Roman State was mainly divided between the order of the Patricians and the class of the Plebeians. Such is the earliest condition of most races and nationalities which have been able to form themselves into separate and distinct States. The men who own the land constitute the one order, and the men who work for them on the soil, or for the supplying of their daily wants, constitute the other. Thus, it necessarily came to pass that when the last of the earlier Roman rulers was driven from his throne, reconstitution of society in Rome was left to the two classes, the Patricians and the Plebeians. The Patricians had been mainly instrumental in bringing the monarchy to an end, for the obvious reason that they were better educated, had more time to give to the observation of affairs outside their own ordinary means of living, and were, therefore, better qualified to form a judgment as to the merits of the system by which they were ruled. The Patricians gained most by the abolition of the kingly system, while for the Plebeians things went on afterwards very much as they had done before, and the struggle for life remained practically the same.

Rome under the Oligarchy. All classes in Rome were now probably agreed that the State and its people would be better served by electing magistrates to rule over its affairs during a certain fixed tenure of office, and then to be succeeded by others elected on the same principle. The idea of equality in citizenship had spread so far, even then, that the Plebeians were entitled to give their votes and to declare their views at public meetings. But the Patricians, the men of means and standing, always had influence enough to keep the offices of State among their own order. The Patricians, therefore, gained much, and at once, by the revolution in favour of a republican system, but for the Plebeians it brought for the time little or no appreciable advantage. The new conditions of the State were not by any means those belonging to a Republic in the more recent sense of the word. Rome was ruled by an oligarchy—that is, by a system of government which gave the whole control of affairs into the hands of a few, that few being the Patricians. The same sort of struggle between the Patricians and Plebeians, the landowners and the labourers, the rich and the poor, the privileged and the unprivileged, has been part of the history of almost every country, but it has seldom been seen more distinctly marked out than in the early history of Rome.

The Power of the Consuls. When the Tarquin monarchy had been brought to an end, the Patricians, who then had to frame a new constitution, resolved upon the appointment, by election, of two ruling magistrates to be called Consuls, who were to be elected annually. These Consuls were not required under this new constitution to consult and take joint action on all State questions, but each was allowed to act on his own judgment concerning affairs coming under his immediate jurisdiction. The reason for this power of individual action was probably found in the assumption that sudden difficulties might arise in different parts of the State, that the Consuls might at a critical moment be widely separated, and that it might not be possible to wait for an opportunity of counsel and joint action. It was provided in the constitution that if any serious difficulty of this kind should arise, or if the two Consuls could not agree on the policy to be adopted at some momentous crisis, they might appoint a Dictator, who should have absolute power for six months. The idea of popular representation had gone far enough in those days to secure for the Plebeians a vote in the election of their officers, but they were not allowed to vote for any but members of the Patrician order.

One result of this principle of consular election was that the Consuls became naturally anxious to conciliate the favour and the goodwill of their own class, and were apt to be somewhat indifferent towards the rights of the Plebeians, who were not allowed to choose anyone of their own order as a rival candidate for election. The Patrician class gave to the Army all its officers. The Romans had a Senate, but the Senate was entirely made up from the Patrician class, and naturally gave its main attention to the interests of the Patricians.

The Plebeians Assert Themselves. The Plebeians soon began to appreciate their numerical strength, and were gradually beginning to feel that by union and organisation among themselves they might be able to make some head against the domination of their masters. The Patricians, let them do their worst, could no longer hold their working classes as mere slaves, and they soon realised that they must, for their own sakes, come to terms with the Plebeians.

In the meantime, there were constant wars going on with neighbouring States; with the Etruscans, who got the better of the Romans in some battles, and at one period would seem to have attempted, if they did not actually accomplish, the capture of Rome ; and with some of the neighbouring Latin races, who struggled to regain their complete independence when they saw the power of the Romans thus threatened by the Etruscan forces. The Plebeians fought side by side with the Patricians in these battles, but the Patricians filled the ranks of the officers and the Plebeians were only common soldiers. The stress and misery caused by these wars fell mainly on the Plebeians, who were most of them either labourers or small farmers, and thus the division between the two classes was inevitably impressing itself more and more on the Plebeians, was making them feel their position intolerable, and inspiring them with readiness for almost any manner of revolution.

The Tribunes. Then, for the first time in Rome's history, some sixteen years after the expulsion of the Tarquins, the Plebeians formed an organisation to protest against the existing system. The Roman legions had just returned to Rome, after a conquering campaign, when they received a command to prepare for a second expedition. The legionary soldiers were all Plebeians, and at this serious crisis resolved to act together for their common interests. Reforms had for some time been promised them, and they now demanded that these reforms should be made realities. The Patricians would not yield as yet, and the victorious legions therefore withdrew from the city and took up their position on a hill some miles outside, a hill afterwards known as Mons Sacer, or the Sacred Mountain. The Patrician rulers found that the time had come when it was no longer possible to avoid making some concession, and they asked the legions to make known the terms on which they would return to the service of the State. The demand of the Plebeians was that certain magistrates should be appointed from the unprivileged orders to protect the interests of the people. There was nothing for it but to yield to these demands. Two Plebeian magistrates, designated Tribunes of the people, were appointed, having as their function and their right the protection of the interests of their own order.

The Land Question. This new system was adopted—had to be adopted—by the ruling class. One concession to justice and fair play naturally led to another, and after a while the number of Tribunes was increased to five, and later still to ten. These Tribunes became a rival ruling power to the Patrician oligarchy and played a most important part in the succeeding history of the Republic. For fully two centuries this struggle is told of in the Roman records. Every improvement in the condition of the Plebeians enabled the working classes to obtain better terms for their labour and especially better terms with regard to the occupation and possession of land. The land question was among the Romans of those early days, as it has been at one time or another in the history of every State, a subject of fierce dispute and agitation. Rome was continually acquiring by conquest large extents of neighbouring land, and it was the custom among the Patricians to divide this land among themselves, and make use of it as their own property. There were among the Patrician order some men of advanced and enlightened views, who bravely and steadfastly advocated the rendering of full justice to the Plebeian order and the establishment of equal citizenship.

An Attempt at Reform. At all periods, such men have been seen in every Patrician oligarchy, just as there have been men found among the leaders of great popular revolutions who did their best to secure just and even merciful treatment for their subdued oligarchical opponents. Some of these reformers among the Roman Patricians endeavoured to bring about a change in the land system by proposing that the Plebeians as well as the Patricians should be allowed a share in the public land. One of these reformers made himself thus so dreaded and detested among the Patricians that an absurd charge was brought against him of endeavouring to attain for himself regal power, and on this charge he was tried, convicted, and put to death. Such misdeeds as this, committed by the holders of power, do not always give to that power an extension of lease, and sometimes have the effect of drawing public attention more suddenly and sharply to the conditions of the lease itself.

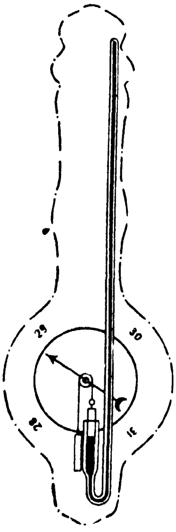
THE PHYSICS OF FLUIDS

Fluid Pressure. The Laws of Fluids. The Barometer. The Syphon. The Pump. The Hydraulic Press. Fluids in Motion

Continued from page 1031

By Dr. C. W. SALEEBY

Fluid-Pressure. In the language of physics, it must be remembered that both liquids and gases, since they flow, are included under the term of fluids. The most important instance of fluid-pressure—the most important fact about fluids—is the atmospheric-pressure. Every one has heard the phrase, "nature abhors a vacuum," but the phrase is far too metaphorical to lead to the truth, and it was not until the time of Galileo that the explanation of the fact was discovered. The credit for it indeed lies with his famous pupil Torricelli. It was found that water would rise about 30 ft. in a pump, but no pump could draw water from a depth of 50 ft. Now, mercury is many times heavier than water, and Torricelli supposed that in all probability mercury would rise in a similar way to water, but to a much less height in proportion to its greater weight; and he was right. If we take a long glass tube closed at one end, fill it with mercury, and then turn it upside down in a vessel containing mercury, we find that all the mercury does not run out of the tube; on the contrary, the mercury sinks in the tube only to such an extent that there remains in the tube a column of mercury which is at a height of about 30 in. above the level of the mercury in the vessel. This is the famous Torricellian experiment, which demonstrates the fact that the atmosphere has a pressure; for the only possible difference between the long column of mercury in the tube and the mercury in the vessel is that the one is exposed to the atmosphere and the other is not. The column of mercury in the tube is supported by the pressure of the atmosphere on the mercury outside it. The space in the tube above the level of the mercury is as nearly a perfect vacuum as can be obtained—that is to say, it contains scarcely any air at all. It is known as a *Torricellian vacuum*. Only a few years after the first experiment of Torricelli, the celebrated writer Blaise Pascal made the experiment of carrying one of Torricelli's tubes to a great height, and found that at the top the level of the mercury was considerably lower. He further found that as he came down the level of the mercury rose, and thus it was plainly shown that the atmosphere possesses a pressure and that this pressure lessens as we ascend in it.



MERCURIAL BAROMETER

The Barometer (from the Greek *baros*, weight, and *metron*, measure). The reader will have already seen that the Torricellian tube is a barometer—that is to say, an instrument for measuring the pressure of the atmosphere. That, of course, is all that a barometer does; it tells us nothing about the weather directly, but is of use in this connection merely because the state of the atmospheric pressure at any given time is by far the most important factor in the determination of the weather.

Torricelli's tube, however, is a very inconvenient barometer, and it is more convenient to have a U-shaped tube, constituting what is called a syphon barometer. This, again, may be easily modified so as to give us what we call a weather-glass. If we place an iron ball so as to float upon the mercury at the open end of the tube, and attach a string to the ball, and a weight to the end of the string by way of balancing the ball, we can conveniently pass the string over a wheel, and to the wheel we can attach a pointer; this pointer can then be made to indicate such legends as "set fair" or "changeable" printed on a circular card. The principle of Torricelli may be employed in a number of different forms, such as the Kew barometer, the marine barometer, and others which do not concern us here. But we may also measure the fluid pressure of the atmosphere by means of another instrument which is much less fragile, since it contains no mercury or glass.

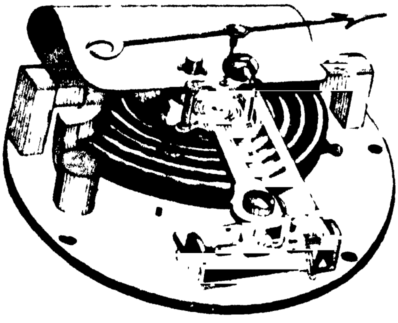
Aneroid Barometer. The aneroid barometer—literally meaning a barometer that contains no liquid—simply consists of a round, flat metal box emptied of air, and having a spring attached to it. The varying pressure of the atmosphere causes the top and the bottom of the box to approximate to one another in varying degrees, which are recorded by the spring, and this spring moves a pointer by means of a lever. The aneroid is quite a convenient little instrument, but it has comparatively small pretensions to accuracy.

When accuracy is wanted it is necessary to correct the readings of even the mercury barometer in various ways; of these the most important is the correction for temperature, so that a first-class barometer always has a thermometer with it. It is hardly necessary to say that the mercury expands as the temperature rises, and unless this were allowed for, we should get the impression that the atmospheric pressure was higher than was actually the case.

The most important points in the construction of a barometer are to make certain that the mercury is pure and absolutely clean, and to boil it. By this last precaution we expel all air and moisture which would otherwise tend to accumulate in the Torricellian vacuum, and would thus make the reading unduly low.

The atmospheric pressure is a direct result of the earth's gravitation, and is simply an expression of the fact that the air has weight, and thus exercises a pressure on anything that may be immersed in it. The English "Standard Atmosphere"—the word atmosphere or sometimes "atmo," is now used in this fashion—is taken as equivalent to the weight of a column of pure mercury 30 in. high, or about 14.7 lb. to the square inch. This is taken at Greenwich, whilst the French take their standard at Paris. Owing to the fact that the earth is not a true sphere, and thus the various points on the surface of the earth are not all at the same distance from the earth's centre, it is necessary when exactness is required to state the latitude where the reading of the barometer has been taken.

Effects of Atmospheric Pressure. Every square inch of our bodies is thus constantly exposed to a pressure of more than 14½ lb., though we are entirely unaware of it, and feel no discomfort. This is essentially due to the fact that the pressure is the same in all directions. It weighs down upon our heads, but it also supports us on all sides. This fact, that *the pressure of a fluid is the same in all directions*, is not only of cardinal practical importance to all, but is also of great interest, as we shall soon see, to the student of physics. A very simple experiment will demonstrate the fact of atmospheric pressure upon ourselves. There is a simple little operation known as "dry cupping," which consists in removing part of the air from a test tube or from a tumbler, as, for instance, by burning something in it, and then suddenly clapping it down upon a portion of the skin. In a very short time, as the hot air inside the vessel cools and contracts, and thus causes a lowering of the atmospheric pressure upon that area of skin as compared with the area that is not covered by the vessel, the covered part begins to swell and rise up into the vessel; this is simply due to the fact that the fluids under the skin are forced by the relatively high pressure exercised upon all the other parts of the body towards the area which has been relieved of part of its pressure.



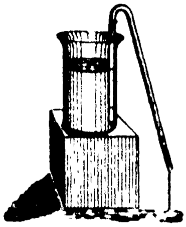
ANEROID BAROMETER

The atmospheric pressure is also of cardinal importance to us in that it is a necessary condition of ability to breathe. Our lungs have no power of deliberately helping themselves to the air that we need. The requisite air passes from the atmosphere into our blood by purely mechanical action, due to the fact that the gaseous pressure in our blood—the atmospheric pressure, if you like—is much lower than the gaseous or atmospheric pressure outside it. But, as readers of the course of CHEMISTRY have already learned, the atmosphere consists of a number of gases, and each of these exercises its own *partial pressure* in proportion to the quantity of it that is contained in the atmosphere. Thus, while the partial pressure of the oxygen in the atmosphere is higher than that of the oxygen of our blood, and thus causes the oxygen in the air to pass into the blood, the partial pressure of the carbonic acid in the atmosphere, on the other hand, is less than that of the carbonic acid in the blood, and thus the carbonic acid passes from the blood outwards to the atmosphere.

Applications of Atmospheric Pressure. The ways in which the atmospheric pressure may be utilised are very numerous, and the most important of them were employed long before they could be explained. A familiar instance is the boy's sucker, a bit of soft, moist leather, with a string attached to its middle point. It is the atmospheric pressure that enables the edge of the sucker to adhere to a smooth stone or other object, which can thus be picked up. Another familiar illustration of the action of atmospheric pressure is shown in the trick of turning upside down a tumbler full of water covered with a card without the water running out. The explanation of this is plainly that the weight of the water upon the inner surface of the card is counterbalanced by the weight or pressure of the atmosphere on its outer surface.

The Syphon. If we take a U-shaped tube and fill it with water, and then immerse one end of it in a vessel of water, having the other end of it below the level of the water in the vessel, the water will be drawn from the vessel and runs out of the lower end. This simple apparatus is called the *syphon*. The explanation of this action is very simple. The water in the second half of the tube, which is turned downwards, naturally tends to run out; but if the water which is at the bend of the tube did not follow there would be a vacuum formed there, and so the atmospheric pressure forces the water in the vessel up the first part of the tube. If, however, the height of the bend were greater than the distance to which the atmospheric pressure can force a column of water, the syphon would not work. That distance, as we saw at the beginning of this section, is about 30 ft. This can be proved if, instead of water, we employ mercury in the syphon, and then put it under an air pump. When the air is pumped out and the pressure thus reduced, the mercury ceases to flow through the syphon.

The student of practical chemistry is familiar with a little glass tube, sometimes graduated, which is called a *pipette*. The straw through which one sucks lemonade is really a pipette. When by sucking one end of the tube we remove the atmospheric pressure upon that end, and allow it to act exclusively upon the lower end, it forces the liquid up into the tube. If, then, we put a finger upon the top of the tube or close the top of the straw with the tongue, we are able to hold the liquid in the tube, just as the mercury is held in a barometer. The principle of the little syringe with which one prepares to fill a fountain pen, or of the superior syringe which has a piston, is exactly the same. Remember that the atmospheric pressure has a limit, or, as someone has remarked, by way of ridiculing the old-fashioned way of talking, "there is a limit to nature's abhorrence of a vacuum." You could not draw up 40 ft. of water in a syringe.



SYPHON

The Pump. The pump is really a special kind of syringe. As far as its principle is concerned, it is nothing more. We require only some mechanical arrangement so that the water which is raised by the atmospheric pressure, when the piston ascends, shall be discharged at the point required when the piston descends. For this purpose we must have a couple of valves both opening upwards, one in the piston, and the other at the bottom of the cylinder which contains the water; and thus when the piston goes down, the water passes through the valve in the piston and escapes by the spout. The force pump approximates more closely to the syringe, for in this case the plunger is solid and the only difference between the two is that, whereas the fluid escapes from the syringe by the same opening as that by which it entered, the force pump has a valve at the bottom of the cylinder opening upwards and an escape pipe at the same level. An instance of the combination of the two methods is furnished by the breathing arrangement of the frog, which consists of a combination of a suction pump and a force pump. The first part of the act of breathing consists in sucking air into the mouth, for which purpose the floor of the mouth drops, as everyone who has observed a frog must have noticed, and thereafter the floor of the mouth is raised and the air is forced into the animal's lungs.

The Laws of Fluids. In discussing the physics of fluids we first of all took up the laws of fluid-pressure by way of an introduction to the subject, since they yield us many interesting facts of practical moment. But now we must go more into the details of the laws which govern the behaviour of fluids, taking first of all the laws of fluids at rest. The technical name for this branch of physics is Hydrostatics; the first part of this word is derived from *hudor*, the Greek word for water. The following are the three great laws of hydrostatics:

(1) Fluid-pressure is always exerted at right angles to any surface which is exposed to it.

(2) At any point in a motionless fluid the fluid-pressure acts with the same intensity in every direction.

(3) The weight of the fluid being neglected, the fluid-pressure is the same at all points in a fluid mass.

The First Law. The first of these laws depends really upon our definition of a perfect fluid. By a perfect fluid we mean one which is perfectly mobile—that is to say, one which is incapable of exercising any oblique pressure upon a surface. Such oblique pressure would be due to the action of friction, and if the fluid be perfectly mobile there can be no friction to act.

Another way of putting this is that a perfect fluid offers no resistance to *shearing stress*. It must be remembered, however, that we cannot experiment with perfect fluids in practice. The fluids we know are not perfect in this sense; they have a certain amount of viscosity—or "oiliness," to use a popular expression and thus offer a considerable resistance to objects passing through them—a resistance which is more than the result of fluid-pressure as such, but partakes of the nature of friction. The resistance of the air has already been spoken of in dealing with the first law of motion; such resistance is not the result of fluid-pressure at all, but of the fact that the air is not a perfect fluid in the sense we have defined. Still less is water a perfect fluid, though the amount of resistance which it offers to the surfaces of a knife passed through it edge foremost is certainly very slight; but if we are to reach the true laws of fluids we must exclude the action of friction, and so we must conceive of a perfect fluid which offers no resistance to any body, save the resistance which is exerted strictly at right angles to the surface of that body, and which is a result, not of its physical condition, but of fluid-pressure.

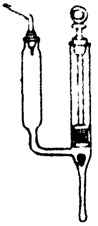
LIFT PUMP

The Second Law of Hydrostatics. The law of the equality of fluid-pressure in all directions was discovered by the French philosopher Blaise Pascal, and is sometimes known as Pascal's principle. It may be reached in two ways—a very conclusive proof of its truth. It may be reached by purely mathematical means which are able to demonstrate that, given the definition of a perfect fluid, the pressure at any point within it must be the same in all directions. But it can also be demonstrated by means of experiment. In the language of logic, we say that the first mode of proof is *a priori* or deductive, whilst the second is *a posteriori* or inductive. We can be absolutely content with our proof of any statement in natural science only when both these methods agree in demonstrating it.

Perhaps the simplest of the many experiments which may be made in order to prove the truth of Pascal's principle is that of corking an empty bottle and weighting it so that it sinks into deep water; it will then be found that the fluid-pressure forces the cork into the bottle and that this occurs in exactly the same way whether the bottle be upright or turned upside down or at whatever angle it be placed.

Plainly, this law implies that a fluid exerts an upward pressure as well as a downward one, but it is as much a mistake to think that a fluid has a definite tendency to force things upwards as to force them downwards. Its pressure is absolutely impartial; this is the cardinal difference between fluid-pressure and the pressure exerted by one solid body on another. This last is exerted in one definite direction only.

The Hydrostatic Paradox. Now, it follows from the above laws that a very small amount of fluid can be made to support an indefinitely great weight in virtue of the fact that the pressure exerted by the small amount of water can give rise to a great force if it be applied to a wide surface. The pressure exerted by a small amount of water communicating with a reservoir of water is transmitted through it, and is felt and is exerted at every point on the surface of that reservoir. This may be technically phrased thus: if we fill with fluid a closed vessel with plane surfaces—plane meaning flat, of course—and then exert a small amount of force on a small surface of the liquid—say, a square inch—an equal force is exerted on every square inch of the flat surfaces in question, and thus the force is multiplied. Hence it is that the force exerted by a very small amount of water may be able to support a weight indefinitely great. The term *paradox* has been applied to this fact because it seems at first sight impossible that power can thus be multiplied. The truth is that power is not multiplied. No mechanical or other arrangement can multiply or destroy power. What some arrangements can and do constantly multiply is not power or energy, but *force*—a word which is technically used in physics to mean one thing and one only—namely, the ability to do work. Thus the hydrostatic paradox so called is really no more a paradox than the action of a lever or a pulley, or any other mechanical arrangement for multiplying force.



FORCE PUMP

PRINCIPLE OF HYDROSTATIC MACHINE

The Hydraulic Press. This is often called the Bramah Press, after the man who effected an important improvement in it. It consists essentially of a strong piston working up and down in a strong cylinder. Into the cylinder there leads an inlet from an ordinary force pump; the piston of this force pump is quite small and can easily be worked by a man, but the force he exerts is greatly multiplied in proportion to the ratio between the size of the piston which he is working and that of the large piston of the Bramah Press. The work done on the pump by the man is precisely equal to the work done by the press; there is no multiplication of power. In order that there should be a real multiplication of power—such as we have said is impossible—the speed of the large piston of the press would have to be the same as the speed of the small piston of the force pump which the man is working. There would then indeed be a creation of power, but this is not so. The piston speed of the pump has to the piston speed of the press exactly the ratio that the area of the press has to the area of the pump. In other words, suppose the piston of the press to be 20 times as large in area as the piston of the pump, it will then move at only one-twentieth of the speed. The mechanical advantage of the machine is that speed is not what is wanted in the press; the speed which in the pump is the direct result of the man's work is translated into force in the press.

The Two Kinds of Fluids. So far we have been able to speak of fluids in general without distinguishing between them, and we have been able to state laws which are true of all fluids. But the reader may have already been somewhat astonished at the inclusion under one term of two things so very different as water and air, and it is now time to distinguish between the properties of two fluids so very different as water and air. The two kinds of fluids are liquids and gases. So far as the laws of hydrostatics are concerned, there is no distinction between them. It is this fact that has led to the abandonment of the old term pneumatics which we have not employed. It is really superfluous, since the general conditions of fluid equilibrium are, as we have seen, identical whether the fluid be liquid or gaseous.

Compressibility of Fluids. It used to be stated that the essential difference between a liquid and a gas is that the first is incompressible, whilst the second is compressible. A gas can be squeezed into a small compass, and when the pressure is relaxed it expands again. It is readily compressible. But if we put some water into a syringe and attempt to squeeze it into a smaller space we find that it is apparently incompressible. There is thus a very great distinction. It is now a long time since the incompressibility of liquids was demonstrated. Bacon, for instance, filled a leaden shell with water, and then hammered and squeezed it in the hope that he would be able to compress the water, but instead it oozed through the lead. Similar experiments were made long ago in Florence, globes of silver and of thickly gilded silver being employed, but always the water oozed through rather than suffer compression.

As to the distinction between liquids and gases, it is necessary to state that liquids are, after all, compressible, though almost infinitely less so than gases. The compression of water is only perceptible under exceedingly high pressures. It is estimated that water is compressible to the extent of about ·00005 of its volume for every atmosphere of pressure.

Boyle's Law. We now come to a very celebrated law dealing with the pressure of a gas which was discovered by the Hon. Robert Boyle in the seventeenth century, and is now known by his name. Boyle proved in his experiments "touching the spring of the air," that the volume of a given mass of gas depends on its pressure. Boyle's law may be stated in several forms. Perhaps the following is the simplest: If the temperature be constant the volume of a gas varies inversely as its pressure. This fact may be expressed in another way. For a given quantity of gas the product of the pressure and the volume is constant. The most popular statement of the law would run something like this: If we take a given quantity by weight of any gas we find that the greater the space it occupies the less is the pressure it exerts, and *vice versâ*.

This exceedingly simple law may be taken as true for all practical purposes, but it has recently been found that it is not absolutely true in all cases; especially it is found that at very high pressures the law is only approximately, not absolutely, observed.

A cardinal difference between liquids and gases is that the latter alone always fill any space that may contain them. You cannot take a small quantity of air and put it in the bottom of a vessel and expect it to remain there; it will expand so as to completely fill the vessel, no matter what its size may be. This fact, of course, is naturally associated with Boyle's law. Upon it depends the principle of the air pump. For if we connect an empty vessel with a vessel containing air the air will at once fill both of them, and thus by a simple mechanical contrivance it is possible to reduce the amount of air in the vessel to an indefinite degree.

The Air Pump. Hence, we have the air pump, and the first point we notice about it is that we can never hope by this means to extract all the air from a vessel. Every time the pump is worked we can extract perhaps half the remaining air, but if we follow this out it will be seen that such a process will never result in completely emptying the vessel. If you owe a man a shilling, and proceed to pay him first sixpence, then threepence, then three-halfpence, and so on, halving the amount of your payment each time, the debt will not be paid even in infinite time; and the case of the air pump is similar. Hence a perfect vacuum can never be thus obtained; but a vacuum which is almost perfect can be obtained by the simplest possible means, and this is the Torricellian Vacuum, which was described when we were dealing with atmospheric pressure and the barometer. The space left at the top of the closed glass tube there described contains nothing but a very small quantity of the vapour of mercury.

In contradistinction to the behaviour of a gas, which always fills any space in which it is contained and which thus enables us to make air pumps, is the behaviour of a liquid, which always has a free surface. Such a surface is horizontal or level—at any rate, we describe it as such, and such it is for practical purposes; but as a matter of fact the surface of a liquid, even water in a tumbler, is not horizontal or level, but is curved, having a convexity which corresponds to, and is indeed part of, the general convexity of the earth. Every part of the surface of a liquid is at the same distance from the earth's centre, and thus the surface cannot be absolutely level, though it is practically so. If we place in a vessel two liquids which cannot mix, such as oil and water, we similarly find that the surface between the two is practically horizontal. The same thing is true in the case of gases. After an explosion in a coal-mine, the carbonic acid, as the miners well know, being heavier than air, seeks its own level, and fills the lower part of the workings.

A large number of considerations in hydrostatics have already been dealt with, amongst these being the principle of Archimedes, the equilibrium of floating bodies, and the whole question of specific gravity and hydrometers.

Physics of Fluids in Motion. As the reader would expect, this part of our subject is known as Hydrokinetics; it is one of the most recondite parts of physics, and it is largely in order to simplify, as far as possible, the study of it that physicists have invented the conception of a perfect fluid, since, when friction and viscosity are taken into account in the study of fluid motion, the whole subject becomes practically too difficult for prosecution; even the motion of perfect fluids is to be investigated only with very great difficulty. Perhaps the most important proposition in hydrokinetics is that arrived at by Torricelli, Galileo's famous pupil. It deals with the speed at which water flows out of an opening in a vessel. The student will be prepared to believe that the rate at which the fluid, say water, flows out will depend upon its pressure, and its pressure will plainly depend upon its weight. We can measure the speed at which water will fall freely from a height, and Torricelli showed that the speed with which the water will issue from the opening corresponds to a fall from the height of the surface of the water above the opening through which it issues. But complications arise. For instance, the actual speed at which the water emerges varies very greatly with the shape of the opening.

The pressure of moving liquids is a subject too complicated to be treated in such a course as this. But it is an exceedingly important subject, and its importance has greatly increased in late years. Upon the pressure of moving liquids depends the turbine, and, as the reader is aware, this form of motor is now rapidly superseding all its predecessors in naval engineering.

Limit of Speed Through Water. The last point to which we need refer is one to which allusion has already been made; it concerns the limits of attainable speed through water. The task which has to be performed by the engines of a ship is to overcome the resistance of the water—more accurately, we should say, by the engines of an already moving ship. Once the ship is in motion, as we have seen in our study of Newton's first law, it will continue to move for ever but for the external resistance, and it is that resistance that the engines have to overcome. Now, it might at first be thought that if engines of 1,000-horse power can develop a speed of, say, 10 knots an hour, then in order to develop double that speed it will be necessary merely to double your horse-power; but this is very far from being the case. In the first place, the resistance of the water to the vessel increases, not as the speed increases, but as the square of the speed—that is to say, if you double the speed, you quadruple the resistance. Further, it is obvious that the distance through which the resistance is overcome in a given time varies according to the speed. Hence, it follows that the horse-power necessary for any vessel must vary according to the *cube* of the speed desired. In other words, if you wish to double the speed of the vessel, you require, not twice the horse-power that you had before, but eight times the horse-power, eight being the cube of two.

THE PROPERTIES OF MATTER

Molar and Molecular Forces. The reader will be rather astonished, perhaps, to observe the title of the section we now introduce. What have we been talking about hitherto, he may say? Certainly we have been talking about matter, but we have been concerned with matter in general, and with the forces which are displayed in and by matter. Similarly, in discussing motion there has been implied the idea of the matter which moves. Nevertheless, there are certain important properties of matter to which we have scarcely alluded. Physicists often employ two very convenient words in order to distinguish between the forces and properties which are to be discussed in the present section. These words are *molar* and *molecular*. The first of these words is derived from the Latin *moles*, a mass, and the second word is the adjective derived from the word molecule, which literally means a little mass. Now, in the course on chemistry a very careful and important distinction has been drawn between the word atom and the word molecule, but it was also pointed out that the use of the word molecule had been altered in recent years. It was noted that nowadays the word molecule is applied to a combination of atoms, whereas only a few years ago the two words were synonymous. Now, when the physicists speak of molecular forces they are using the word as much in the old sense as in the new. The reader who comes to this section, after having studied in the course on Chemistry the difference between the meanings of atom and molecule, is entitled to expect that when we come to speak of molecular forces we mean the forces displayed by molecules as distinct from atoms. But, in point of fact, the forces of which we are to speak are in some cases really molecular in the precise modern meaning of the term, but are not infrequently atomic. Only too often the physicist is not prepared to say whether these forces, and these peculiar properties of various kinds of matter, are due to the character of the molecules, or to the character of the atoms that go to make up these molecules. So much for one of the many explanations that are necessary in consequence of changes in the use of words.

Chemical and Physical Differences. Now, we must have even another explanation. In the very first page of our course we distinguished between physics and chemistry by declaring that, whereas chemistry deals with particular kinds of matter, physics deals with matter in general, and that distinction is perfectly true. Chemistry seeks to analyse the various kinds of matter and reduce them to what are called their elements, and then it proceeds to take these elements one by one, and to discover all that may be known about each of them. The forces and properties with which chemistry has to deal are thus said to depend on the chemical composition of whatever substances it may be studying. But, in addition to these chemical forces, there are a number of other kinds of forces displayed in certain kinds of matter which do not at all depend upon the chemical composition of the matter in question, but upon its *physical state*. Familiar instances of the distinction we are seeking to recognise may be furnished by water and carbon. So far as the chemist is concerned, water is still water, consisting of constant proportions of hydrogen and oxygen, no matter whether it be liquid water or solid water or gaseous water. But the physicist is profoundly interested in the differences between these three kinds of water. There is no *chemical* difference, we observe, between ice and water vapour; the chemical composition of each is the same, but the physical difference between them is profound. Or, again, take carbon; the diamond and charcoal, and the black material in a so-called lead pencil, these all have the same chemical composition—they simply consist of carbon. But the physical differences between them are very great indeed, and are deeply interesting to the physicist. The chemist says that the kind of matter in each of these three specimens is one and the same; and that, of course, is an exceedingly important fact. But here the physicist takes up the discussion, and says: "I thank you for this extraordinary discovery that diamond and charcoal and graphite all consist of the same kind of matter; but now I am going to inquire what it is that enables one and the same kind of matter to show itself in such profoundly different forms as diamond and charcoal, or as ice and steam. The kind of matter is the same, the atoms and the molecules are identical, but plainly they must be related to one another—in one way in diamond, and in another way in charcoal. The differences are not chemical, but physical."

THE ORDNANCE SURVEY

History and Scope of Ordnance Survey Maps. Land Measurements in Great Britain and Abroad. Metric System of Measurements

By A. TAYLOR ALLEN

History. The Ordnance survey is a trigonometrical survey of the United Kingdom, and is performed by officers and men of the Royal Engineers.

Apart from all scientific and other considerations, it must be admitted that this survey of the United Kingdom has, so far as the public is concerned, more than fulfilled the object it was intended to accomplish. It is, in fact, the only reliable survey of the country that is published and available for reference.

The preparation by the Government of a general map for any portion of the country was first proposed after the rebellion of 1745, when the want of a reliable map of the northern parts of Scotland was much felt by Army officers. This was the first State survey of any portion of the King's dominions that was ordered for military purposes. This extensive work was entrusted to Lieutenant-General Watson, the Deputy Quartermaster of Great Britain, who, with the aid of Major-General Roy, was engaged for 10 years in executing the work. The map was drawn to a scale of 1¼ in. to the mile, but it was never published. Twenty-nine years elapsed before any other portion of the country was surveyed by the State, and then the work was undertaken for scientific, rather than for military, purposes It was with the object of calculating the difference of longitude between the observatories of London and Paris that, in 1784, General Roy measured a base-line on Hounslow Heath, which started a series of triangles extending to Dover.

Origin of the Present Ordnance Map. A few years later the Government decided upon having a general survey of the United Kingdom prepared for military purposes. This was the origin of the present 1-in. Ordnance map, and the triangulation carried out by General Roy in the south-eastern counties became the basis of the general triangulation. As the survey was extended westwards it was considered advisable to measure another base-line. This was done on Salisbury Plain, and for purposes of verification other lines were measured, at Misterton Carr, in 1801, and Rhuddlan Marsh, in Flintshire, in 1806. The first sheet of this survey was published in 1801. About this period the public utility of State charts for purposes other than those of a military character began to be recognised. The public demand for better maps than were then available became so great that surveyors were engaged for the purpose of pressing forward the completion of the 1 in. survey that was then in hand.

The principal triangulation in Scotland was commenced in 1809. But little progress had been made when the officials and surveyors were withdrawn to enable them to carry forward the detail maps of England. Going north again in 1813, the work was pushed steadily forward for six or seven years. In the three following years the Scottish survey, although not altogether suspended, made but little headway.

The survey of Ireland was required for political and administrative purposes, and the Government decided that the map should be prepared to the scale of 6 in. to the mile, and the chief strength of the surveying corps was transferred to Ireland for this purpose. The map was completed in 1845.

The value of this 6-in. map having been proved, a survey for a similar map was commenced in the northern counties of England in 1840, and in the following year secondary operations for a map of Scotland, also on a larger scale, were begun, but in 1851 a committee of the House of Commons recommended that the 6-in. maps be stopped and the 1-in. maps completed in detail.

Triangulation of the United Kingdom. The primary triangulation of the United Kingdom was finally completed in 1852. It comprises in all 250 trigonometrical stations, and a map showing all these lines, which is very seldom seen, presents the appearance of a huge spider's web, with its centre laid on Salisbury Plain. The average length of the sides of the triangles is 35·4 miles, and the longest measures 111 miles. The accuracy, or otherwise, with which the triangulation was carried out was at one time tested, with extremely satisfactory results. The length of the base-line measured in Ireland on the border of Lough Foyle was calculated through a series of triangles from the base on Salisbury Plain, and the length so found differed from the measured base by only a little more than 5 in. The distance apart of these two bases is about 360 miles, and their length about 41,614 ft. and 36,578 ft respectively.

From the opinion of a large number of the most eminent scientific and practical men it was found that the great preponderance of opinion was in favour of a scale of $\frac{1}{2500}$th, or nearly 1 in. to the acre. This scale was therefore ordered in May, 1855.

The charge of the Ordnance survey was transferred to the Board of Agriculture on its formation in 1890.

Maps and their Uses. The standard maps published by the Ordnance Survey Department, and obtainable from Edward Stanford, of 12, 13, and 14, Long Acre, W.C., the sole London agent, and from the Ordnance Survey Office, Southampton, are as follows.

General Map. A *general map* of the whole of Great Britain and Ireland on the scale of 1 in. to 1 statute mile, and prepared on one uniform system. On the coloured maps the county boundaries are shown by a softened band of colour. The larger parks are green, the principal roads brown, the rivers and canals blue, and the railways red.

There are two series for England and Wales, known as the New Series and the Original Series. The New Series is published in sheets engraved in outline with contour lines. The size of the work on the sheets is 18 in. by 12 in., representing 18 by 12 miles. The Original Series is published partly in sheets and partly in quarter sheets, hills being shown by vertical hachures.

This map is of use principally as a road map. It is too small for any great detail to be shown. It is the cyclist's favourite scale. Steps have been taken to ensure that each sheet shall be revised every 15 years. The second revision has already begun.

County Maps. *County Maps*, on the scale of 6 in. to one statute mile, engraved or drawn, and published in sheets and (for certain counties) quarter sheets.

A full sheet represents 6 miles by 4 miles, and contains 15,360 acres. A quarter sheet represents 3 miles by 2 miles. The sheets of each county are numbered horizontally by Roman numerals.

The quarter sheets bear the numerals of the full sheet, of which they form a part, with the addition of the initial letters N.W., N.E., S.W., S.E., according to the position they occupy on the full sheet.

These county maps show more detail than the general map, but are not large enough that any accurate work may be set out from them, but very valuable for estate purposes.

Parish Maps. *Parish Maps*, on the scale of $\frac{1}{2500}$th, or 25·344 in. to 1 mile, which is approximately equal to 1 acre for every square inch on the map. A sheet represents 1½ miles by 1 mile, and contains 960 acres. Sixteen plans on this scale form one 6-in. full sheet, and bear a double reference number.

This is the best size for general work. The smaller scales are too close, and the larger ones make very cumbrous maps, if, say, for an estate, two or three are joined together.

Town Maps. *Town Maps*, on the scale of $\frac{1}{500}$th, or 126·72 in. to 1 mile, or 41·66 ft. to 1 inch, which is adopted for all towns of more than 4,000 inhabitants. Each plan represents 24 chains by 16 chains, and contains 38·4 acres, and shows the arrangement of the beds in the gardens.

The sheets of these maps bear a treble number. Maps of certain towns have been published on the scale of $\frac{1}{528}$th, or 10 ft. to 1 mile, and many on the scale of $\frac{1}{1056}$th, or 5 ft. to 1 mile. A scale of 88 divisions to 1 in. is applicable to the latter map.

The map of the United Kingdom, on the scale of $\frac{1}{1000000}$th, is expected to be published during the current year. It is claimed that it should be useful as a wall map and for educational purposes.

Maps for Schools. A new departure has been made in the supplying of schools with specially printed Ordnance Survey maps at a very low price. These maps are issued on a written undertaking from the headmaster, or other responsible representative of the school, that they will not be placed on sale, and will be used for educational purposes only. Over 46,000 of these maps were supplied in 1903-04.

Engineers and surveyors find the Ordnance maps and area books absolutely necessary for much of their work. The Ordnance Survey reference books give the area of every field and enclosure to the thousandth of an acre, in acres and decimals.

A résumé, giving full particulars of all the Ordnance and geological survey maps, plans, etc., can be obtained from the agents for the sale of maps.

Edward Stanford	..	London.
J. Menzies & Co.	..	Edinburgh.
Hodges, Figgis & Co.	..	Dublin.

Ordnance Datum. The bench marks of the Ordnance surveys are of this pattern ⊼ and are known as Ordnance bench marks (O.B.M.).

The horizontal line represents the spirit level, and the three strokes forming the arrow represent the legs of the stand of the level (technically known as the tripod). On the sheets of the Ordnance Survey the levels of the several bench marks are numbered in feet and decimals of a foot above mean high-water mark at Liverpool, which is assumed to be 0·650 of a foot below the general mean level of the sea. These heights have been determined at many points throughout the country: each is designated by the mark referred to, being in a wall, or footpath, or milestone, at the spot indicated on the Ordnance map.

Land Measures. Originally land measure differed in various parts of England, and was governed by the custom of the particular locality in which the land was situated, hence the term "Customary Measure."

Now, however, land measure for the whole of England is governed by Statutes 34 Henry VIII., 5 George IV., chap. 74, and 5 and 6 William IV., chap. 63; hence the term "Statute Measure."

Consequently, in old documents, one occasionally comes across plans, etc., giving the area of lands in customary acres, roods and perches, and it is, therefore, necessary to reduce *customary* to *statute*, and sometimes statute to customary measure.

The same remark applies also, in some cases, when dealing with land in Scotland or Ireland, or other parts of the world, where the land measure differs from our statute measure.

1. By the Act 5 George IV., chap. 74 (June 17th, 1824), it is enacted: "That our

present yard shall be denominated the 'Imperial standard yard'; and shall be the unit, or only standard measure of extension, whereby all other measures of extension whatsoever, whether the same be lineal, superficial, or solid, shall be derived and computed; and that all measures of length shall be taken in parts, or multiples, or certain proportions, of the said standard yard; and that one-third part of the said standard yard shall be a foot, and the twelfth part of such foot shall be an inch; and that the rod, pole, or perch in length, shall contain five such yards and a half: the furlong, two hundred and twenty such yards; and the mile one thousand seven hundred and sixty such yards"

2. By the same statute it is enacted that all superficial measures shall be computed by the said standard yard, or by certain parts, multiples, or proportions thereof; and that the rood of land shall contain one thousand two hundred and ten square yards; and that the acre of land shall contain four thousand eight hundred and forty such square yards, being one hundred and sixty square rods, poles, or perches.

3. By the Act 5 and 6 William IV., chap. 63 (September 9th, 1835), all *local* or *customary* weights and measures are abolished, not only in England and Wales, but also in Scotland and Ireland.

Multiples of the Yard. The yard being the British standard length, it is multiplied into chains, furlongs, and miles, and divided into feet and inches, the chain of 22 yards being divided into 100 parts, or links, each of which measures 7·92 inches.

In the school table books 5½ yards is called 1 rod, pole, or perch, and the square formed by this length, containing 30¼ sq. yd., is called 1 sq rod, pole, or perch.

Surveyors object to this confusion of terms, and are generally agreed that the term pole shall be used for lineal measure, and perch for square measure, so that areas in land surveying are usually stated in acres, roods and perches, any fraction over being stated as ¼, ½, or ¾, to whichever of these it is nearest.

The Ordnance surveyors use three places of decimals for the fractional perches, giving an appearance of accuracy which the work itself will not warrant, as an allowable error is 1 perch per acre.

Formerly, by custom, the perch varied in different parts of England, and with it, consequently, the acre also varied in proportion In Devonshire and part of Somersetshire, 15 ft., in Cornwall, 18 ft., in Lancashire, 21 ft., and in Cheshire and Staffordshire, 24 ft. were accounted a perch. In the common field-lands of Wiltshire there was a customary measure of a different nature—*viz.*, of 120 instead of 160 statute perches to an acre, so that 30 perches of statute measure made 1 rood of customary, or 3 statute roods made 1 customary acre, or 30 statute perches made 1 rood, and 4 such roods made 1 acre customary measure.

It may be observed that 4,840 sq. yd. make 1 statute acre—3,630 made 1 Wiltshire acre, 4,000 made 1 Devonshire or Somersetshire acre, 5,760 made 1 Cornwall acre, 7,840 made 1 Lancashire acre, and 10,240 sq. yd. made 1 acre of the customary measure of Cheshire or Staffordshire.

The Scotch acre contained 1,244$\frac{1}{9}$ sq. yd., and the Irish acre 3,000 sq. yd. more than the English statute acre; while the Scotch mile was 216¼ and the Irish mile 480 yards more than the English mile.

The standards of measurement in London for testing chains, rules, and rods are situated in the Guildhall and on the north side of Trafalgar Square, and may be used free of charge.

Reducing to Statute Measure. In many old surveys and plans the area is given in local and customary acres, rods, and perches, consequently it is necessary to give the method of reducing local or customary measures of land to statute measure and statute to customary measure.

METHOD No. 1. When the number of feet in a customary perch is given, reduce the customary quantity to square feet, and divide by 272·25, the number of square feet in a statute perch, and again divide the quotient by 160, the square perches in an acre for acres; and the remainder, multiplied successively by 4 and 40, and divided successively by 160, will give the roods and perches statute measure.

METHOD No. 2. When the number of square yards in a customary acre is given, reduce the area (customary measure) to acres and decimals of an acre, multiply by the number of square yards in a customary acre, and divide by 4840, the square yards in a statute acre, and reduce the decimals to roods and perches by multiplying successively by 4 and 40.

Problem No. 1. Reduce 17 a. 0 r. 9 p. customary measure, when the customary perch is 15 ft., to statute measure.

Russia	1,110	..
Scotland	1,976½	..
Spain	5,028	..
Sweden	7,233	„

French Measures. The French system of measuring is easy to comprehend, it being necessary to remember only the are, mètre, and stère. The others are all related in a tenfold proportion, the preceding part of the word making the distinction, the terminations all being the same—decamètre, hectomètre, kilomètre, etc., signifying 10, 100, 1,000, etc., times the mètre; and decimètre, centimètre, millimètre, signifying 10, 100, 1,000 parts of the mètre.

We append a table showing English standard equivalents of lineal, superficial, and cubic measurements in the metric system, and the metric equivalents of the English standards. It is a simple matter to reckon out these equivalents from one system to the other with an accurate table as a basis of calculation. For instance, hectares may be reduced to acres by multiplying by 2·4711, and acres may be expressed in hectares by dividing by 0·40467. In drawing out the equivalents of mixed quantities, it facilitates the calculation to reduce the expression to its lowest term. Thus, to bring 5 acres 3 roods 2 perches to ares, the expression should be reduced to perches and divided by 25·29. The quotient will be square metres or hundredths of an are.

LINEAL MEASUREMENT

ENGLISH DRAMA SINCE SHAKESPEARE

A Concise Review of the Leading Dramatic Poets and Playwrights in the Seventeenth, Eighteenth, and Nineteenth Centuries

Continued from page [illegible]

By J. A. HAMMERTON

Character of the Restoration Drama. No comparison is possible between the drama of the Elizabethans and that of their immediate successors. It is all contrast—the contrast, one great critic has said, of Hyperion and a Satyr. We shall not go so far as that. We have to remember Mr. George Meredith's eulogy of Congreve. But all the brilliancy of the "comic dramatists of the Restoration" cannot blind us to the fact that when women made their first professional appearance on an English stage, the chief theme of the plays that were written at that time was the ridicule of the marriage state, to the end that the ribald laughter of a dissolute Court might be provoked and the cheap cynicism of "the man of the world" encouraged in its vacuity. It may be mentioned, however, as interesting in this connection, that the first *rôle* professionally rendered by a woman in a public theatre in this country was that of Desdemona in "Othello." Mr. Nichol Smith has been at some pains to show that the eighteenth century rendered tribute where tribute was due, but the playwrights of the latter half of the seventeenth century translated Shakespeare for stage purposes much as Bottom was "translated." Even Dryden is not exempt from the mania for painting the lily in fancy hues.

The why and the wherefore of a study of the Restoration drama are so admirably set forth in one of Macaulay's "Essays"—the review of Leigh Hunt's edition of the Works of Wycherley, Congreve, Vanbrugh, and Farquhar—that we can hardly do better than commend this essay to the reader at the outset.

Dryden and His Contemporaries. Again passing over THOMAS RANDOLPH (b. 1605; d. 1635) as only of exotic interest, the first name that claims our attention is that of SIR WILLIAM DAVENANT (b. 1606; d. 1668). Davenant's work well reflects the spirit of reaction against Puritanism; much of it was unworthy of the man's better parts. His "heroic play" of the "Siege of Rhodes" is the germ of English opera, and he introduced many accessories to the theatre, including the orchestra. THOMAS KILLIGREW (b. 1612; d. 1683) is the author of a comedy, "The Parson's Wedding," which, we are told by Pepys, was originally acted by a female cast. He built a playhouse in 1663 on the site of the present Drury Lane Theatre.

JOHN DRYDEN (b. 1631; d. 1700), at the instance of Davenant, wrote an absurd adaptation of "The Tempest," and a capital blank verse tragedy, "All for Love," on the lines of "Antony and Cleopatra." He adapted the "heroic couplet" to the English drama, thus winning the approval of Charles II. and the ridicule of the Duke of Buckingham in "The Rehearsal." His characters are, in the main, abstractions; he uses noble language to convey ideas full of extravagance. But his tragedies of "Don Sebastian" and "Cleomenes," together with the comedies of "Marriage à la Mode" and "The Spanish Friar," contain much that is eminently readable. Avowedly, he wrote plays not because the work was congenial, nor because he thought of posterity, but to make money. Considering the variety of his literary output in other directions, it is remarkable that his position as a dramatist stands so high as it does. The student should not miss his "Essay on Dramatic Poesy."

SIR GEORGE ETHEREGE (b. about 1635; d. 1691) was one of the first to employ rhyme in comedy. There was little harmony in his character. His plays are pictures of the high life of the period, and altogether unsuitable for general reading. His three comedies, "The Comical Revenge; or, Love in a Tub," "She Would if She Could," and "The Man of Mode; or, Sir Fopling Flutter," may be classed with the plays of TOM D'URFEY (b. 1653; d. 1723), THOMAS SHADWELL (b. 1642; d. 1692), and Mrs. APHRA BEHN (b. 1640; d. 1689). D'Urfey deserves special mention because of his songs and the friendship which both Addison and Steele extended to him.

William Wycherley (b. 1640; d. 1715). Wycherley was one of the two great lights of Restoration comedy. Said Evelyn:

> "As long as men are false and women vain,
> Whilst gold continues to be virtue's bane,
> In pointed satire Wycherley shall reign."

Like Dryden, Wycherley made a rather feeble first effort at writing for the stage. Also like Dryden, but with greater success, he sought and found inspiration in France and Spain. He may be described as the originator of our comedy of manners. "He was a ruffian," says Mr. Gosse, "but a ruffian of genius." "The only thing original about Wycherley," writes Mr. W. C. Ward, "the only thing which he could furnish from his own mind in inexhaustible abundance, was profligacy." He was a faithful mirror of his own time. His chief comedies are "The Plain Dealer" and "The Country Wife." The one is founded on Molière's "Le Misanthrope," and is praised by Hazlitt as "a most severe and poignant moral satire"; the other loses our respect and much of such admiration as its workmanship claims when compared with its sources, Molière's "L'Ecole des Maris" and "L'Ecole des Femmes." Wycherley's own life provides the most effective satire on the social ideals of his period.

William Congreve. In the works of William Congreve (b. 1670; d. 1729) the comedy of manners attains its apogee. "The Old Bachelor," "The Double Dealer," "Love for Love," "The Mourning Bride," and "The Way of the World" were all written before their author was thirty years old. Then came sinecures and literary sterility. Congreve was, and remains, a master of repartee and accomplished insolence. He wrote better than Molière; but Molière's stage method and dramatic style preserve his plays alive while those of Congreve, if we except "Love for Love," which has been described as the finest prose comedy in the English language, are consigned to the study. "In every point," writes Mr. G. C. Ewald, "Congreve maintained his superiority to Wycherley. Wycherley had wit; but the wit of Congreve far outshines that of every comic writer, except Sheridan, who has arisen within the last two centuries. Congreve had not in a large measure the poetical faculty; but, compared with Wycherley, he might be called a great poet. Wycherley had some knowledge of books, but Congreve was a man of real learning. Congreve's offences against decorum, though highly culpable, were not so gross as those of Wycherley, nor did Congreve, like Wycherley, exhibit to the world the deplorable spectacle of a licentious dotage." Thackeray declared that "the Congreve muse is dead, and her song choked in Time's ashes." "See," he exclaimed, "there's the cup she drank from, the gold chain she wore on her neck, the vase which held the rouge for her cheeks, her looking-glass, and the harp she used to dance to! Instead of a feast we find a gravestone, and in place of a mistress a few bones." Some phrases from the Congreve comedies long since passed into the common speech: "Music hath charms to soothe the savage breast," "Heaven has no rage like love to hatred turned, nor hell a fury like a woman scorned," "Married in haste, we may repent at leisure" are among them.

Vanbrugh and Others. What Sir John Vanbrugh (b. 1664; d. 1726) lacked in grace he had in coarse wit and facile inventiveness. The epitaph—

> "Lie heavy on him, earth! for he
> Laid many heavy loads on thee,"

alludes to his achievements as the architect of Blenheim and Castle Howard, not to his authorship of "The Relapse," "The Provoked Wife," and "The Confederacy." With Vanbrugh may be compared George Farquhar (b. 1678; d. 1707), who, in some directions as a dramatist, improved on his predecessors in cogency of construction, and whose incidental verse indicates a power that—possibly for reasons connected with a hand-to-mouth sort of existence—was never fully cultivated. The famous line from his "Twin Rivals"—

> "Necessity, the mother of invention"

—is singularly apposite to its author. Horace Walpole said of Farquhar's plays that they talk the language of a marching regiment in country quarters. He wrote best what he wrote last, "The Recruiting Officer" and "The Beaux' Stratagem." He marks the transition from Restoration licence towards the purer, if more conventional, stage methods belonging to the reign of Queen Anne and the Early Hanoverians.

Thomas Otway. In Thomas Otway (b. 1651; d. 1685), it has been well observed, "there is no relief, no pause from the war and clamour of passion." He lived tragically, wrote tragedy, and died young. Gloomy as are his plays and devoid of lyrical beauty, they reach the heart by sheer force and knowledge of human nature. "More tears," said Sir Walter Scott, "have been shed probably for the sorrows of Belvidera [in "Venice Preserved"] and Monimia [in "The Orphan"] than for those of Juliet and Desdemona." Of "Venice Preserved," which awakened the praise of Dryden, Hazlitt, and Taine, versions have been made in French, German, Dutch, Russian, and Italian. Otway is a strayed tragedian, belonging by genius, if not by time, to the Elizabethans.

The Lesser Dramatists. Other names that can only be given bare mention as those of dramatists of some, but lesser, note are: Nathaniel Lee (b. 1653; d. 1692), who collaborated with Dryden in "Œdipus," and who is best represented by "The Rival Queens"; John Crowne (d. 1703), author of "Thyestes" and "Sir Courtly Nice"; Nahum Tate (b. 1652; d. 1715), whose version of "King Lear," in which Cordelia survives and marries Edgar, held the stage till the middle of the nineteenth century; Colley Cibber (b. 1671; d. 1757), who appears to have been better as a comedian than as a playwright, though his version of Shakespeare's "Richard III." has been frequently performed in the provinces even of recent years; Nicholas Rowe (b. 1674; d. 1718), whose "Jane Shore," is still acted, and who in "The Fair Penitent" (adapted from Massinger's "The Fatal Dowry") drew the prototype of Richardson's Lovelace; Thomas Southerne (b. 1660; d. 1746), whose "The Fatal Marriage" and "Oroonoko," founded on novels by Mrs. Aphra Behn, enjoyed a century's popularity; Elkanah Settle (b. 1648; d. 1724), author of a "heroic" piece of bombast called "The Empress of Morocco"; John Gay (b. 1688; d. 1732), author of "The Beggar's Opera" and the libretto for Handel's "Acis and Galatea"; and Richard Savage (d. 1743), who wrote a comedy, "Love in a Veil," a tragedy, "Sir Thomas Overbury," and inspired Johnson to the writing of one of the best, if by no means the most accurate, of short biographies. Here brief mention must also be made of Joseph Addison (b. 1672; d. 1719) as the author of "Cato," a tragedy which has enjoyed in literature a European reputation; Sir Richard Steele (b. 1672; d. 1729), "the father of sentimental comedy"; Samuel Johnson (b. 1709; d. 1784), as the author of "Irene," a tragedy which all Garrick's zeal could not make successful, and concerning which Boswell has some entertaining pages; Samuel Foote

(b. 1720; d. 1777), a social satirist in Jonson's vein; **DAVID GARRICK** (b. 1717; d. 1779), whose adaptations, together with his prologues and epilogues, are of merit; **GEORGE COLMAN** the elder (b. 1732; d. 1794), who collaborated with Garrick in "The Clandestine Marriage," and wrote "The Jealous Wife"; **GEORGE COLMAN** the younger (b. 1762; d. 1836), author of "The Heir-at-Law," a comedy of sterling qualities; **JOHN HOME** (b. 1722; d. 1808), author of "Douglas"; and **RICHARD CUMBERLAND** (b. 1732; d. 1811), author of "The West Indian." To the comedies of **HENRY FIELDING** (b. 1707; d. 1754), written after the manner of Congreve, may be applied the description given by Jonson of Cardinal de Perron's translation of Vergil—namely, "That they were naught."

WILLIAM WYCHERLEY

WILLIAM CONGREVE

RICHARD BRINSLEY SHERIDAN

THOMAS OTWAY

Goldsmith and Sheridan. **OLIVER GOLDSMITH** (b. 1728; d. 1774) was unlucky in the circumstances attending the production of the first of his two comedies, "The Good-Natured Man." It was poorly acted; but genius prevailed. The lovable qualities found in all he wrote distinguished both "The Good-Natured Man" and "She Stoops to Conquer." These two comedies, the proceeds of which made their author for the time being a man of fortune, have been referred to as the greenest spots in the dramatic history of the period to which they belong, and as containing "wit without licentiousness; humour without extravagance, brilliant and elegant dialogue, and forcible but natural delineation of character." **RICHARD BRINSLEY SHERIDAN** (b. 1751; d. 1816), whose personality and romantic love-story have been made clearer for us by Sir Herbert Maxwell's study of "The Creevey Papers," is as popular on the stage as Shakespeare; to the graceful humour of Goldsmith he added the wit, without the grossness, of Congreve. Of his four comedies, "The Rivals," "The School for Scandal," "The Critic," and "The Duenna," the first and second are the best known. Here is what his contemporary Creevey says: "'The Rivals' upon its first performance was damned. When Sheridan got to Slough [his home], and told his wife of it, she said, 'My dear Dick, I am delighted. I always knew it was impossible you could make anything by writing plays; so now there is nothing for it but my beginning to sing publicly again, and we shall have as much money as we like.' 'No,' said Sheridan, 'that shall never be. I see where the fault was; the play was too long and the parts were badly cast.' So he altered and curtailed the play and had address or interest enough to get the parts newly cast. At the expiration of six weeks it was acted again, and with unbounded applause." Of Sheridan's comic muse Hazlitt says: "She does not go prying about into obscure corners or collecting idle curiosities, but shows her laughing face and points to her rich treasure, the follies of mankind. She is garlanded and crowned with roses and vine-leaves; her eyes sparkle with delight, and her heart runs over with good-natured malice; her step is light, and her ornaments are consummate." Lord Byron wrote on learning of Sheridan's death:

"Long shall we seek his likeness
—long in vain,
And turn to all of him which
may remain,
Sighing that Nature formed but
one such man,
And broke the die—in moulding Sheridan."

The Drama of the Nineteenth Century. When the nineteenth century opened, Shakespeare shared with Goldsmith and Sheridan all the distinctive honours. The other dramatists, in the stage sense of the term, were hard to seek.

"**MONK**" (**MATTHEW GREGORY**) **LEWIS** (b. 1775; d. 1818), of "The Castle Spectre"; **THOMAS HOLCROFT** (b. 1745; d. 1809), author of "The Road to Ruin"; **JAMES SHERIDAN KNOWLES** (b. 1784; d. 1862), who wrote "The

"Hunchback" and "The Love Chase"; **Bryan Waller Procter** (b. 1787; d. 1874), whose tragedy of "Mirandola" is amongst the least of his literary achievements; **Joanna Baillie** (b. 1762; d. 1851) and **Elizabeth Inchbald** (b. 1753; d. 1821) are among the best of the playwriters of the time. **Samuel Taylor Coleridge** (b. 1772; d. 1834) translated Schiller's "Wallenstein," and wrote a five-act tragedy, "Remorse," which, says Mr. Swinburne (paraphrasing Jonson), contains "little worth praise or worth memory, except such casual fragments of noble verse as may readily be detached from the loose and pliable stuff in which they lay embedded." It ran for twenty nights at Drury Lane, in 1813. Another half-forgotten tragedy of the period is that of "Bertram," by the Rev. **Charles Robert Maturin** (b. 1782; d. 1824), which was produced by Kean, at Drury Lane, in 1816, on the recommendation of **Lord Byron** (b. 1788; d. 1824), whose own contributions to literary drama—"Manfred," "Marino Faliero," "Sardanapalus," "The Two Foscari," "Cain," "Heaven and Earth," "Werner," and "The Deformed Transformed"—will be dealt with in connection with his poetry, as will "The Bride's Tragedy" of **Thomas Lovell Beddoes** (b. 1803; d. 1849); and "The Cenci," by **Percy Bysshe Shelley** (b. 1792; d. 1822). Byron's plays found their way to the stage for other reasons than their intrinsic value for acting purposes. "Ion," a Greek tragedy by Sir **Thomas Noon Talfourd** (b. 1795; d. 1854), and "Philip van Artevelde," by Sir **Henry Taylor** (b. 1800; d. 1886), are both works for the reader rather than for the playgoer. "Philip van Artevelde" is a romance that has received far too little attention. One of the most popular of the dramatists of the nineteenth century was **Edward Bulwer, Lord Lytton** (b. 1803; d. 1873), whose plays, "The Lady of Lyons," "Money," and "Richelieu," for all their artificialities of sentiment, still retain a strong hold upon the public. This is also the case with such plays as "Society," "Caste," and "Ours," by **Thomas William Robertson** (b. 1829; d. 1871); "Masks and Faces" and "It is Never too Late to Mend," by **Charles Reade** (b. 1814; d. 1884); "Still Waters Run Deep," by **Tom Taylor** (b. 1817; d. 1880); "Black-Eyed Susan," by **Douglas Jerrold** (b. 1803; d. 1857); "London Assurance" and "Colleen Bawn," by **Dion Boucicault** (b. 1822; d. 1890); and "The Two Roses," by **James Albery** (b. 1838; d. 1889). Comedy lightened into burlesque and extravaganza on the one hand, the work of **Planché**, the brothers **Brough**, **Henry James Byron**, and others; and on the other, into sparkling operas, of which those composed by Sir **Arthur Sullivan** (b. 1842; d. 1900) and **William Schwenck Gilbert** (b. 1836) are incomparably the best.

While comedy was degenerating, the purely literary drama was receiving some noteworthy additions in "Strafford," "A Blot on the 'Scutcheon," "The Return of the Druses," and "Luria," by **Robert Browning** (b. 1812; d. 1889); the "Queen Mary," "Harold," "Becket," and "The Foresters" of **Alfred Tennyson** (b. 1809; d. 1892); and "The Queen Mother," "Rosamond," "Atalanta in Calydon," "Chastelard," "Bothwell," "Mary Stuart," "Erechtheus," "Marino Faliero," "The Sisters," "The Tale of Balen," and "Rosamund, Queen of the Lombards" of **Algernon Charles Swinburne** (b. 1837); the "Demeter" and other plays of **Robert Bridges** (b. 1844); the "Scaramouch in Naxos" and a notable version of Coppée's "Pour la Couronne" of Mr. **John Davidson** (b. 1857); and the "Cosmo de' Medici" and "The Death of Marlowe" of **Richard Henry Horne** (b. 1803; d. 1884). At the present time, where the English drama is not a reflection of Continental authorship, it is indebted to two working playwrights in particular, Mr. **Arthur Wing Pinero** (b. 1855), author of plays as dissimilar as "Sweet Lavender" and "Letty"; and **Henry Arthur Jones** (b. 1851), author of "The Silver King" and "The Liars." The plays of these two dramatists do not indicate a very high tone in the society which they depict. With the drama of Mr. **George Bernard Shaw** (b. 1856) the young student need not be greatly concerned. Quite distinct is the work of Mr. **Stephen Phillips**, whose "Herod" marked the close of the century with a note which awakened aspirations after better things.

A Brief Bibliography

JOHN DRYDEN.
Best Plays. Edited, with Introduction and Notes, by George Saintsbury. 2 vols. Mermaid Series.
Dramatic Poesy. By T. and W. T. Arnold (Frowde), and by D. Nichol Smith (Blackie).

SIR JOHN VANBRUGH.
Select Plays. Edited by A. E. H Swain. Mermaid

GEORGE FARQUHAR.
Dramatic Works. Edited by A. C. Ewald. Nimmo.

RICHARD STEELE.
Complete Plays. Edited by G. A. Aitken. Mermaid

WILLIAM WYCHERLEY.
Complete Plays. Edited by W. C. Ward. Mermaid.

THOMAS SHADWELL.
Best Plays. Edited by George Saintsbury. Mermaid.

THOMAS OTWAY.
Best Plays. Notes by Hon Roden Noel. Mermaid.

WILLIAM CONGREVE.
Complete Plays. Edited by A. C. Ewald. Mermaid.
The Comedies. Intro. by G. S. Street. Methuen.

OLIVER GOLDSMITH AND RICHARD B. SHERIDAN.
Plays. Methuen's "Standard" and Cassell's "National" Libraries.

Commercial Aspect of Research and Heroism. The Cultivation of Rubber, Tea and Tobacco. Future of Pasture-farming. Science in the Bakehouse and Machine-shop

By ERNEST A. BRYANT

IF we could have a tabulated list of the callings from which men and women have realised wealth, the result would be surprising. We should miss the names of some of the greatest men in the history of science; the names of many who have added new territories to the map of civilisation; of men whose discoveries in medicine and surgery and in philosophical research are inscribed in imperishable characters in the story of human progress.

The Roll-call of the Wealthy. The man who conquers plague and pestilence may not be of the company; but the man who devises an instrument for the wholesale destruction of life will be there. We may look in vain for the names of Milton and Bunyan, Defoe and Goldsmith, Johnson and Lamb, for Haydon and Lawrence and Watts, but we shall find the names of men who have contributed to the commonplaces of life. It is sadly inevitable that among our grandest figures who have put forth great, heroic effort for the good and betterment of humanity, there must be those who, poor and sad, have only at the last to beg that they may lie, as Browning makes Paracelsus plead to lie,

"Within some narrow grave,
Not by itself—for that would be too proud—
But where such graves are thickest."

Happily, in our list we should have also our heroes who had won reward, as the world views reward—reward in material gain. That man who by his discoveries and inventions increases the common store of wealth and happiness is as much a hero as the man who successfully commands an army and comes to Parliament to be ennobled and endowed with wealth. Still more a hero is he who rises early and takes rest late to devote his life to problems whose solution shall render his fellows more and more immune from the ills to which flesh is heir. The history of the laboratory thrills with the stories of health sacrificed—aye, of lives innumerable given by these self-denying sons of science. It is good and encouraging to find even these unselfish ones represented by a few in the catalogue of the fortunate. Dr. Roux is awarded the Osiris prize of £5,000 for his scientific labours in bacteriology, more particularly in regard to his successful work with the anti-toxin for diphtheria. A new explosive, or a new quick-firing gun would have brought him twenty times as much; but there is encouragement in the prize. Harvey was not one penny the richer for making the greatest discovery in the history of physiology—the discovery of the circulation of the blood.

Facilities for Scientific Research. The modern tendency is to assist with liberal hand the man engaged in work of such importance to the world. Wealthy corporations, established for quite different purposes, now make pecuniary grants, and funds and associations exist solely for the encouragement of scientific research. It is not unreasonable to hope that the day has finally passed for the scientist to be compelled to spend his laborious days in penury.

A War for Humanity's Sake. There is so much for him still to do. Every outbreak of influenza means the sacrifice of more lives than would result from cholera, plague, or war. We track the malaria-carrying mosquito to his breeding ground in the swamps and marshes, the puddles and mud-holes of ill-paved towns. Having tracked him, we are able to exterminate him. Science traces the birth of influenza to a not dissimilar origin—to water stagnating within the cracks in the earth's surface caused by long preceding drought. Within the rifts thus opened is some mysterious poison which is liberated when the sun dries up the water by which it has been absorbed. So far science has taken us; but it has not been able to step in at the fountain head of the mischief and say, once and for all, that then and there the merciless affliction shall cease. No; influenza once started on its fell career sweeps the whole world—north, south, east, and west. Within the memory of almost the youngest who read this paper it has robbed two thrones of their heirs—the thrones respectively of Great Britain and Belgium. We know how to deal with the effects, though the terrible death-roll from an influenza epidemic shows that we cannot be certain of success in any single case. We certainly do not know how to deal with the cause. Wealth and the gratitude of the whole world await the man who can give us immunity from this deadly enemy of the race.

What Science Has to Find. Consider next a smaller subject, but one of great importance to England. In spite of all that our great chemists have been able to perform in synthetic chemistry, they have been utterly baffled, so far, in their attempts to find a substitute for lead in the glazing of pottery. This, perhaps, may not seem to possess any special significance for the man or woman who buys the goods. But the question is one of life and death to those engaged in producing the ware. Lead-poisoning is the great enemy of those who glaze the pottery of commerce. A Royal Commission inquired into the subject a year or two ago, and presented a carefully considered report. The result was discouraging. No one can, as yet, devise a substitute for the lead compounds necessary to the process of manufacture. Either the use of the lead must continue, or the industry must be ruined. If English potters do not manufacture this class of ware with lead as a constituent, foreign firms will. Here, then, is a field for the chemist of to-morrow. Manufacturers would welcome and richly reward the man who could give them the requisite formula to take the place of the health-destroying lead, and the many toilers who now jeopardise their lives by the present methods would heap blessings upon the head of their saviour.

Improving on Nature. Having resolved into its original elements the particular material upon which his attention is fixed, the synthetic chemist can, as a rule, build up in his own laboratory an excellent imitation of the original. By a slight re-grouping of the elements he can largely change the character of the result. Between what he can do in the matter of a substitute for this lead-glaze and the exact compound he actually wants there may be but a little link missing. So long, however, as that one link is lacking, so long is the whole incomplete. A similar result is found in other fields. One of the greatest of new industries is to be the scientific cultivation of rubber. Until comparatively recently, we left the provision of this substance entirely to Nature. It was very dear; the supply was not of dependable uniform quality; but merchants had to bear with it as it was, though declaring themselves ready and willing to pay fifteen per cent. more all round if they could but rely upon rubber of level excellence.

Here, then, obviously, was the opportunity of the synthetist. He makes indigo and a thousand other things for which hitherto we have had to go to Nature; why not rubber? There was a curious difficulty. As every schoolboy knows, the rubber is drawn in fluid form from the tree. It might seem that if we can bring peaches and grapes from the other side of the world without so much as disturbing their bloom, it ought not to be impossible safely and securely to transport this sticky mass. But again and again the attempt to get it over to Europe was baffled. The composition changes when the latex has been drawn from the tree, and upon arrival here is quite different from the fluid which the native artificially coagulated in the depths of the African forest. As the rubber would not come to us, we have had to send men to the rubber to investigate it where it grows. This has been done, and operations to this end are still being carried out with exemplary thoroughness.

A Too Costly Success. Can we now produce rubber artificially? The answer is in the affirmative, but with a qualification. Carl Otto Weber, whose recent death is a great loss to the rubber industry, on which he was the foremost authority, did take it to pieces, as it were, and build up an artificial rubber. Possibly it was as good as the average original, but no purpose was served: the copy was more costly than the natural product. What the young chemist has to do is to follow up the investigations of Weber and perfect a system for a cheap supply of the artificial article

Meanwhile, those who feel that their future lies abroad may with profit study the question of rubber cultivation. The demand for rubber is so enormous that it can no longer be left to haphazard supply. In South America and other places, particularly in Ceylon, the cultivation of the rubber-tree is becoming a fine art. Tea supplanted coffee in Ceylon; now rubber is challenging tea. Here it grows to perfection, and careful husbandry yields handsome profits to the grower. Whereas a few years ago the quantity required for England was measured by hundredweights, now the figures run into many thousands of tons each year. Thousands of patents exist for articles made or fitted with rubber. To the physician and surgeon it is indispensable; it is the only substance in the world which makes a permanently silent roadway; it is the only thing which makes riding possible by bicycle, motor, or cab; and, to go still further, it is the one substance upon which depends a firm from whom are due a million and a quarter tobacco pouches every year. Yet, in spite of all the trade in this rubber, extensive scientific culture is still relatively a new thing. The man who finds a new tract of rubber-trees in Bolivia claims it like a gold-mine. This is an industry well worth the study of the man who listens to the call of distant lands.

Supplying the World's Teapot. Tea-planting is another such industry. Men who visited India and Ceylon years ago, and remember the methods of drying by hand and the clumsy manipulation of the whole process of old days, are amazed now upon revisiting the country to witness the improvements and economies effected by the introduction of machinery. They see, moreover, that finality of improvement has not by any means been reached. Tea-growing is a subject in which Britons, of all men, should be interested. The United Kingdom consumes each year more tea than all the rest of Europe and the United States combined, the total reaching no less vast an amount than 256,000,000 lb. for a single year, representing over 6 lb. of tea per head of population. With so huge a quantity consumed, we ought consistently to follow out the argument that there is no waste in chemistry, and be able to show that the spent leaves of the tea are turned to some account. That may, perhaps, be of the future. It is more easy to distribute tea than to collect the leaves.

The same principle applies to tobacco. The finest manure for this plant is tobacco ash, which simply restores to the earth the mineral properties of which it has been exhausted by producing the tobacco. Acute cultivators have noted an interesting little sum in reciprocity in this connection. Four pounds of tobacco yield one pound of ash; one pound of ash, placed as manure upon the land, serves for four more pounds of tobacco. Two million acres of the earth's surface are under tobacco cultivation, and that area is capable of infinite extension, for tobacco will grow in any climate, though, of course, the tropics are most favourable to the best crops, as is the case with rubber. From both plants the seeds are carefully collected, which, in the latter case, is a modern departure

The Future of the Pasture. This leads to another consideration, bringing us home to the pastures of the homeland. It would be hard to-day to convince the farmer that motor traffic will ever seriously compete with the horse which he so well loves. It was not less difficult to persuade our fathers that the locomotive engine would drive the great lumbering coaches off the roads. Trains might run, they agreed, but they would never be drawn about the country by engines; they would be "wound" along the lines by pulleys and ropes from point to point, after the fashion which men still living remember to have seen on London railways. But the locomotive did come, and did conquer; and the motor has come, and in turn is conquering. Therefore, horses, while they will never disappear from all classes of work, must in course of time greatly diminish in numbers. That is serious for the horse breeder. It is still more threatening to a larger industry—to agriculture.

Who shall find a market for hay and straw when the motor replaces the horse? Even now, with many horses to feed, there is, in the case of a favourable summer, an excess of clover hay in the country. What is to happen when fewer horses require fodder? The last man whom the average farmer would think of consulting is he to whom he will have eventually to turn—the chemist.

Not everything is possible to the chemist. Certain economic difficulties remain insuperable even to the scientist The conversion of the balance of hay and straw into commercial commodities would not be chemically impossible. The difficulty which does baffle him, however, is that of cost. No matter how ingenious his methods, the chemist cannot command success for uncommercial enterprises. Straw and hay may be of the best quality, and comprehensive of virtues innumerable, but the price charged for transporting it from the farm to the town, and of storing it there, is so excessive as to make manufacturers' ventures with these products as constituents highly unlikely. Other means must, then, be sought.

The Chemist to the Rescue. He will have to discover new methods of combining the surplus hay with other substances as a food for fattening stock. Instead of growing clover for horses, farmers will grow it for cattle. Whatever he may do with ourselves, the chemist will never feed sheep and bullocks on a tabloid diet. There must be bulk as well as nutriment for stock. Hence the cattle must have their good, weighty fodder, and the farmer will have to grow it for them. The disappearance of the horse, then, viewed from this standpoint, will not be of serious moment. The net result will be to benefit the agriculturist. With new means devised for feeding cattle, with British crops as an essential basis, money will be kept in the country which now goes abroad for feeding-stuffs—for which we pay yearly an enormous sum. The outcome will be to place more stock upon our pastures, and out of threatened evil good will come.

With foodstuffs in mind, it is not inopportune to refer to an article of a different character. At the present moment England stands pre-eminent for her biscuits. No other country can even distantly approach her, nor, with hope of success, enter her markets. She supplies the biscuits of practically the whole world, and has done so ever since biscuits first were. But here is a trade which has found it necessary, in spite of its strong position, to keep abreast of the times. For every variety of biscuit which the confectioner sold a dozen years ago, there are now a score. One of the most popular of the innovations is the flavoured biscuit. This is the line along which the development of the future has to come. Excellent as have been the results already attained, better are being sought, and there is still room for improvement.

Science in the Bakehouse. According to a very eminent authority the biscuit-making trade—taken not, of course, with reference to any one branch, but as a whole—does not so thoroughly appreciate the value of essences and flavourings as it might do. With the makers of essences and superior soap the study of essences, with all their blendings and other possibilities, is a fine art. The biscuit-maker needs a laboratory and a chemist. Perhaps some factories are already equipped in this manner; if so, they need not fear an extension of the principle. For there is rivalry to come. Seeing that England has so long led in the manufacture of biscuits, naturally her machinery is the best at present made. She is not longer to retain unchallenged the possession of such advantages. At the present time, in America and elsewhere, manufacturers are setting up British machinery for the purpose of competing with the Old Country. This machinery has to pay a duty of 45 per cent. on entering the United States, whereas, of course, machinery built there by American firms pays nothing. In spite of that, however, the English makers are kept busily employed in laying down plants for our future rivals.

English Experts for America. As they get the machinery, the Americans ask for men. "Send us experts to operate these plants," they are saying. Where are the experts? England has not one to spare; she needs more for her own works. The man who is qualified from the chemical standpoint and from—for lack of a better term—the cooking standpoint, is an exception. Very properly, British firms keep their trade secrets, and no man is at liberty to dispose of them. The trade, however, will have to be studied from a different standpoint. England cannot compare at present with the Continent in the matter of expert knowledge of essences and flavourings, so that while she has the best of practical biscuit-makers, she has to fear the expert theorist who will impart his knowledge to the practical baker.

Every student of industries must have observed to what a remarkable extent trades nationalise or localise themselves. A hundred different trades have as many distinct areas in London. In the provinces you find cotton in Lancashire, wool in Yorkshire, boots in Northamptonshire, lace in Nottinghamshire, straw-plaiting in Bedfordshire, hosiery in Leicestershire, and so on. The constant effort of nations, as of local authorities, is to introduce and foster new industries. Japan, during the last forty years, has made herself a great industrial, as well as warlike, power solely by this means. Every modern art she possesses she has acquired by copying from the West—by sending students abroad, by getting Englishmen and Germans, and American and Frenchmen there. We in this country profited by unsought advantages of a like kind long ago.

Our Beneficent Invasions. St. Bartholomew's Eve helped almost incredibly to make us the first commercial nation of the world. The Huguenot refugees, fleeing to England for asylum and refuge from the bloody tyrant by whom their deaths had been decreed, brought with them the peaceful arts of which they were masters. And that which they knew they taught in England. They brought with them and established here the woollen, worsted, and napery industries, silk-weaving, tapestry, dyeing, glass-making, pottery, and paper-making; they gave us men of light and leading for the Church, statecraft, and the Law, gallant men and skilled for the Army and Navy, artists, poets, men of letters. The peaceful invasions to which now and again we are subjected assume a different form.

We, like Japan, have again and again to Westernise. The Americans cause us to remodel our methods of making boots and matches We have to be content with typewriters of their make, with their calculating machines, their electrical inventions, their dictionaries, and, very largely, their furniture. We are about to model our building methods upon theirs. If we do not, they will do the building for us, as indeed they have done in more than one instance already—notably at Manchester, and in the electrification of the London District Railway. If only another Yerkes would come to take in hand the Port of London, the metropolis might hope. The spirited manner in which these industrial invasions are met and countered—for Englishmen of dash and genius carry the war into the heart of the enemy's camp at times—shows that Britons have not lost their old adaptability, their power easily and rapidly to conform to new demands and new conditions. The old theory that once a nation is mistress of a certain industry she shall for ever remain mistress of that industry is breaking down. Increased competition by rivals, who but the other day were inconsiderable, has taught England a lesson by which she has not been slow to profit.

The New Spirit. The need for this modernising of method was expressed by King Edward, as Prince of Wales, in a notable speech delivered in London some years ago: "Hitherto English teaching has relied chiefly on training the intellectual faculties, so as to adapt men to apply their intelligence in any occupation of life to which they may be called. And this general discipline of the mind has, on the whole, been found sufficient until recent times; but during the last thirty years the competition of other nations, even in manufactures which were once exclusively carried on in this kingdom, has been very severe. The great progress that has been made in the means of locomotion, as well as in the application of steam for the purposes of life, has distributed the raw materials of industry all over the world, and has economised time and labour in their conversion to objects of utility. Other nations which did not possess in such abundance as Great Britain coal—the source of power—and iron—the essence of strength—compensated for the want of raw material by the technical education of their classes, and this country has, therefore, seen manufactures springing up everywhere, guided by the trained intelligence thus created. Both in Europe and America technical colleges for teaching, not the practice, but the principles of science and art involved in particular industries have been organised in all the leading centres of industry. England is now thoroughly aware of the necessity for supplementing her educational institutions by colleges of a like nature. Most of our great manufacturing towns have either started or have already erected their colleges of science and art. In only a few instances, however, have they become developed into schools for systematic instruction."

National effort has yet to be regarded as essential. Hitherto personal initiative has been mainly the factor. The success of personal effort makes us hopeful for the issue of schemes founded upon a broader base. The result of the work of men of modern ideas in specific industries may be traced in many directions.

Revolutions in Industry. What business man could afford to dispense nowadays with a roller-top desk? That is, supposing he has ever used one. All those desks came originally from America. The idea was not new. In the homes of many of us there are old-fashioned bureaux with the flexible lattice top. It was the application of the idea which was new. That was American. It required special machinery; that, too, was American. For some time the Americans completely dominated our market for these desks and similar furniture for the office and the library and study. English cabinet-makers have taken the lesson to heart, and to-day, by the aid of new and excellent machinery, are sweeping the American manufacturer out of the market. New machinery has been laid down in many of our great boot manufactories, and the result again is the extinction of American goods. The English manufacturer has only to give his mind to the accomplishment of reform; the result is assured. The best English work is still incomparable. We shall later on, trace other important industries in which similar revolutions are in progress, and point finally to directions yet open to men with initiative and industry.

Continued from page 1048

By Dr. C. W. SALEEBY

Diamond. The diamond is almost absolutely pure carbon. Its nature was proved by the celebrated French chemist Lavoisier, who succeeded in burning diamonds, and proving that the sole product of their combustion was carbonic acid (CO_2). We know now also that if the diamond be raised to a white heat in the absence of oxygen, it swells up, and is transformed into a black mass, which is practically a shapeless lump of charcoal. Diamonds which are not perfectly white owe their colour to the presence of oxides of various metals, such as iron. Diamond is the hardest substance known. It occurs in many crystalline forms, but they are all derived from the cube. The property which gives it its peculiar beauty is its very high power of refracting light—that is to say, bending rays of light, and, incidentally, breaking them up. [See Optics, in the course of PHYSICS.] Diamonds are most abundantly found at the Cape and in Brazil, but formerly they were only known in the Deccan in India. The hardness of the diamond gives it a practical use as an instrument for cutting glass and for drilling rocks. The value of diamonds is variously stated to increase as the square or as the cube of their weight.

Graphite. Graphite is the second allotropic form of carbon which we have to consider. It occurs in Cornwall and Cumberland, in the United States, and elsewhere. The carbon which separates out from cast iron when it is slowly cooled is graphite. It crystallises in the form of six-sided plates. Apparently in order to confuse the student, graphite is known by two names which attempt to persuade him that it consists of lead. These are *blacklead* and *plumbago*. Besides its use in making pencils and blacking grates, graphite is also employed for the making of moulds for iron casting, and is also mixed with fireclay for the making of crucibles.

Charcoal. Charcoal is an amorphous form of carbon, and is obtained from two distinct sources. *Animal charcoal* is obtained from bones by heating them in the absence of air, and is thus also known as bone-black or bone-charcoal. It, however, is an exceedingly impure form of carbon, a very large part of it consisting of phosphate of lime. It has a peculiar affinity for colouring matters, and is used in the process of refining sugar so as to remove colouring matter from it. It is also an ingredient of blacking, and is employed as a pigment. Lampblack is another impure form of carbon, which is obtained by the imperfect combustion of oil, and is also used as a pigment.

Wood Charcoal. This is made by charring wood. It is far from pure, but contains a much larger proportion of carbon than does animal charcoal. The time-honoured way of preparing it is by piling the wood in a heap, covering it over with turf, and then setting it on fire. The result is a number of lumps of wood charcoal which retain the original shape of the pieces of wood. It is an ingredient of old-fashioned gunpowder, mixed with sulphur and nitre or saltpetre, the nitrate of potassium. This form of carbon has a peculiar physical property ; it is extremely porous, and thus will hold a large quantity of gas ; but more than that, it has a power, hitherto unexplained, of condensing gases on its surface and in its substance. A given quantity of wood charcoal will absorb or occlude an amount of gas which would otherwise occupy hundreds of times its own volume. Wood charcoal is thus a deodorant, having the power of removing bad smells ; but it is also in some measure a disinfectant, for it accumulates oxygen in its pores in a highly condensed and therefore very active form, by which means it is enabled, so to speak, to burn up microbes and bring their life to an end.

Gas Carbon. Another variety is gas carbon—porous, greyish black, and exceedingly hard—which is deposited in gas retorts during the process of making gas from coal. The coal gas consists largely of compounds of hydrogen and carbon, and it is from these that gas carbon is obtained. It also is amorphous.

Coal. Coal is one of the most important forms of carbon, of which it contains from about 70 per cent. in the poorest forms of coal up to 97 per cent. in anthracite. Anthracite coal is a direct product of the activity of chlorophyll, the substance which we mentioned in the last section. It consists of the carbon remains of certain forms of giant ferns which flourished upon large portions of the earth's surface many geological ages ago. Coal is the characteristic constituent of the geological stratum which is known as the carboniferous. [See GEOLOGY.] There is good scientific ground for the poetical description of coal as " buried sunshine " ; for the activity of the chlorophyll, to which it owes its formation, depends entirely upon the action of sunlight. When coal is heated in the absence of air, as for instance in the manufacture of coal gas, we obtain not only the gas carbon which is deposited on the upper surfaces of the gas retorts, but also the product which we call coke. This by no means consists of pure carbon, but it is very much purer than coal.

The briefest reference may be made to some very interesting experiments by Sir James Dewar upon the behaviour of the various forms of carbon at extremely low temperatures, especially in relation to their power, already referred to, of occluding gases. He finds that when charcoal, for instance, is immersed in liquid air, its power of gaseous absorption is extraordinarily increased. We have yet to reach the explanation of these, and countless other facts, which belong to the new science of physical chemistry.

Oxides of Carbon. Carbon forms two compounds with oxygen, both of which are of great importance. The simplest is known as *carbon monoxide*, or *carbonic oxide*, and has the formula CO. It is an odourless, tasteless, colourless gas, and is produced in nature when carbon is burnt with an amount of oxygen which does not suffice for its complete oxidation. For, when carbon is completely oxidised, there is produced the substance known as carbon dioxide, or carbonic acid, which has the formula CO_2. Carbonic oxide may also be formed by reduction of carbon dioxide by means of red-hot carbon, according to the equation

$$CO_2 + C \quad 2CO.$$

This process may be observed in a hot fire, and is of importance, because it occurs in coke stoves. In an ordinary fire, the coal which is near the front, and thus receives abundance of oxygen, undergoes complete combustion, and yields carbon dioxide; but as this gas passes backwards over the red-hot coal at the back of the fire it is reduced, according to the above equation, and yields carbon monoxide; but as this arises it meets with a better supply of oxygen, and is itself burnt to form carbon dioxide again. It burns with a blue flame, which may be constantly seen in a very hot fire or a charcoal stove. The formation of carbon monoxide in this fashion is a very frequent cause of death abroad, where charcoal is frequently burnt in rooms insufficiently ventilated.

Now, why is this gas poisonous? We are able to answer the question very precisely. Carbonic oxide is poisonous in a special sense, as carbon dioxide is not, because it is capable of combining with the hæmoglobin of the blood, which was mentioned in our discussion of iron. Carbonic oxide forms a very firm union with hæmoglobin, yielding a compound which has a very bright red colour, and gives a characteristic tint, which has been described as cherry-red, to the blood of persons poisoned by this gas. This compound is a very firm one, and it prevents the hæmoglobin of the blood thus occupied from performing its proper function of carrying the oxygen of the air from the lungs to the tissues. Thus the patient dies of a kind of suffocation. The especial danger of this gas is that its accumulation in a room offers no warning to the senses of smell or taste.

Carbonic Acid. We may as well at once admit that this is not really an accurate name for what should more properly be called carbon dioxide (CO_2). A more accurate name, often employed, but unfortunately calculated further to puzzle the student, is *carbonic anhydride*. The meaning of this last word must be explained. An anhydride (which really means *not water*) is an acid from which have been removed the elements which correspond to the constitution of water—that is, in the proportion of two atoms of hydrogen to one of oxygen. The name carbonic acid should properly be confined to the union of carbon dioxide and water. If we combine the two formulas, H_2O and CO_2, and write the product with the hydrogen first—as we usually write the name of an acid—we get the formula H_2CO_3, and it is this substance to which the name of carbonic acid should properly be confined. This substance is not a mere chemical fiction; it has a real existence, though it is very unstable. If carbon dioxide be dissolved in water, we find that this substance is present. In the first place, such water has a very faintly acid taste—the taste of soda-water; in the second place, it is like an acid in its action on litmus paper.

Litmus. Litmus is a vegetable substance which is prepared from certain lichens, and acts as an extremely delicate test for the presence of acids and alkalies. A solution of it in water, carefully prepared so that not a trace of free alkali or free acid is present, has a violet colour, and blotting-paper may be impregnated with it. If, now, such litmus paper, as it is called, be exposed to the faintest trace of free acid, it immediately turns red, but if to the faintest trace of free alkali, it immediately turns blue.

Carbon Dioxide. We are entitled to conclude, then, that the solution of carbon dioxide in water is more than a mere solution, and includes a true acid H_2CO_3, to which, if we were to be strict, we should have to confine the name of carbonic acid; but as soon as the water is heated the acid is broken up and carbon dioxide, or carbonic anhydride—we now see the reason for the name—is given off.

This most important substance is a colourless gas, all but free from smell and taste, and is normally produced by the complete oxidation of carbon. This is true, whether the carbon be coal in the fireplace, or carbon combined in living tissues. Every living thing, from microbes up to man, incessantly produces carbon dioxide as the consequence of its life. The gas is also produced as the result of the decomposition of dead organic matter. It is found in coal-mines also, and as it will not support life constitutes a source of great danger to the miner, who calls it *choke-damp*. It is also produced in mines as the result of explosions of another gas called *fire-damp*, and then the coal-miner calls it *after-damp*. This is responsible for the loss of many lives. The gas is heavier than air, and thus accumulates in the lowest parts of coal-mines, old wells, and the like. The most convenient test for ascertaining whether it is safe to descend a well, for instance, consists in lowering a lighted candle and seeing whether it will continue to burn. It will, of course, be at once extinguished if plunged into an atmosphere of carbon dioxide. Upon the weight of carbon dioxide depends the singularly brutal form of scientific experiment which is performed, or used to be performed, at the Grotto del Cane, in Italy, where a layer of carbonic acid lies upon the floor of the cave. Thus, human beings can walk in with impunity, but dogs which are completely immersed in the carbonic acid promptly succumb. Hence the name of the place.

Carbon dioxide is produced when we heat or otherwise decompose a carbonate. This was the famous experiment of Joseph Black, whom we mentioned in our initial chapter. He heated chalk, which we now know to consist of calcium carbonate, or carbonate of lime ($CaCO_3$), and showed that it was converted into quicklime whilst losing an "air" which had formerly been "fixed" in it. This he therefore called "fixed air." We now know that it is carbon dioxide, and we are able to write the simple equation which represents the decomposition:

$$CaCO_3 = CaO + CO_2$$

Precisely the same thing happens when a carbonate, such as carbonate of soda, is treated with a strong acid. The acid takes to itself the base of the carbonate, which in this case is sodium, and turns out carbonic acid, which immediately shows itself in the form of bubbles of gas.

Carbonic Acid and the Air. Carbonic acid occurs as a constant constituent of the atmosphere, to the extent of about ·04–·06 per cent. This latter quantity is regarded by hygienists as about the limit which should be set to the amount of this gas permitted to occur in inhabited air; at any rate, the "physiological amount," as it may be called, should barely exceed ·06 per cent. The presence of green plants is important in modifying the percentage of carbon dioxide in air. Flowers and plants are beneficial in a room in daylight, for they reduce the amount of carbonic acid in the air by means of the process which was briefly mentioned when we were discussing iron and chlorophyll; but at night they are powerless. Day and night, like every other living thing, plants breathe, taking in oxygen, giving out carbonic acid, and thus tending to vitiate the air. Under the influence of sunlight this familiar process is more than neutralised, so far as we are concerned, by the converse process, but at night the plant continues to breathe and consume the air, whereas its salutary function ceased at sundown. Therefore remove all plants and flowers from a bed-room at night. The simultaneous performance of two exactly opposite functions in the daytime is perhaps rather confusing. At any rate, our case is simple enough. Day and night we simply add to the carbonic acid in the air, nor can we regain the valuable carbon squandered thereto, except through the mediation of the plant.

Supposed Accumulation of Carbonic Acid. Now, if we picture the entire surface of the earth, on which man is so rapidly increasing, and if we consider that every living thing is incessantly producing carbonic acid during its life, whilst the same gas is evolved from its remains after its death, it may seem probable that at length all the oxygen of the air will be used up and replaced by carbonic acid. The reverse action performed by the green plant in daylight could delay this accumulation, but could not arrest it. Thus the imagination has pictured the last survivor of the human race as gasping for air somewhere on the side of Mount Everest; while his fellow beings, both animal and vegetable, lay drowned beneath him in the rising sea of carbonic acid. But there has now been discovered a compensatory process. We have reason to believe that the percentage of carbonic acid in the air is practically constant everywhere, and at all times. This is a very fortunate circumstance, for our breathing entirely depends for its success upon the presence of a proper percentage of oxygen and a small enough percentage of carbonic acid in the respired air.

The Sea to the Rescue. There is every reason to believe that it is the sea which controls and keeps constant the amount of carbonic acid in the air. Sea-water contains a varying proportion of the carbonate and the bicarbonate of magnesium, the latter salt containing twice as much carbonic acid as the former. Now, the proportion of carbonate to biarbonate varies with the percentage of carbonic acid in the air above the sea. When that percentage tends to rise, what is called the *partial pressure** of the carbonic acid in the air also tends to rise, and the result of raising this pressure is to drive the excess of carbonic acid into the carbonate of magnesium in the sea-water, turning it into bicarbonate. If, on the contrary, there be, let us say, a large forest near the sea, which tends to reduce the amount of carbonic acid in the air and so to lower its partial pressure, some of the bicarbonate of magnesium in the sea-water is decomposed into carbonate and carbonic acid, which latter is given back to the air, the balance being thus restored. Thus, in accordance with the laws of what modern physical chemistry calls *dissociation*, there is an automatic arrangement for regulating and keeping constant the amount of atmospheric carbonic acid. The fact that the percentage of carbonic acid is so constant in different places is easily explained by the incessant movements of the atmosphere. The percentage of this gas in the air of a great town certainly rises during the day, but when the fires go out the wind is soon able to restore the original state of things. This is one of the reasons why night air, despite the popular prejudice against it, is healthier than day air.

Solid Carbonic Acid. We have heard much lately about liquid air and even liquid hydrogen. We also know that Sir James Dewar has succeeded in even solidifying both air and hydrogen. The first gas to be solidified by the chemist was carbonic acid; by the application of sufficient cold and pressure, it may be readily obtained as a substance which has all the appearances of snow. It is not too cold to be held for a short time in the hand.

* See "Atmospheric Pressure" in PHYSICS.

Elements Allied to Carbon. The list of elements which have certain resemblances to carbon includes *silicon*, *tin*, *lead*, all of considerable importance, and three rare elements, *titanium, zirconium, and thorium, only the last of which is of any practical importance. It is the essential constituent of gas-mantles for incandescent lighting. Silicon,* as we have already seen, is exceedingly abundant, but it is never found in the free state in Nature. It may be extracted from its double fluoride with potassium by means of metallic sodium, and then is obtained as a brown powder. But it may also be obtained in black six-sided plates, and therefore presents us with another illustration of allotropy. It is obtained in its crystalline form by dissolving the amorphous powder in molten zinc, and then allowing the solution to cool. Mention has already been made of the resemblances between this substance and carbon, the former the most important element in the organic, and the latter the most important element in the inorganic world. One atom of silicon combines with two of oxygen to form the very abundant compound *silica*, which has the formula SiO_2. Like carbon, silicon combines with hydrogen to form a gaseous compound, and many of the carbon compounds can be paralleled by similar compounds, which differ only in containing carbon instead of silicon. Just as we have carbonates, the foundation of which is CO_2, so there are silicates, the basis of which is SiO_2. Glass consists entirely of silicates, the nature of the base varying in different kinds of glass. Flint glass, for instance, consists of alkaline and lead silicates, while other bases, such as sodium, potassium and calcium, enter into the composition of other kinds of glass. The silicate of sodium, which has the formula Na_2SiO_3—compare the carbonate of sodium Na_2CO_3—goes by the name of water-glass, and is used in solution for the purpose of making wood and other substances fireproof. For a full discussion of the important substance *glass* the reader is referred to the special section dealing with that subject.

Tin. Tin occurs in Nature in the form of its oxide, which is called *tinstone* and has the formula SnO_2. It occurs in Cornwall, as the ancients seem to have known, and also in Australia and Mexico. [See METALLURGY.] Tin forms two series of salts, the stannous and the stannic, the meaning of which terminations was explained in our consideration of iron. The stannous chloride has the formula $SnCl_2$, and is known as salts of tin. It is used in dyeing and other trades. Stannic chloride has the formula $SnCl_4$, and is also used in dyeing.

One of the most useful properties of tin is its power of forming alloys with other metals. Tin and lead form pewter and various other substances, such as solder and Britannia metal. Tin combined with copper also yields bronze, and what is called speculum metal, which is capable of taking a high polish, that renders it valuable in optical instruments. The chief use of tin is in the making of tin plates.

Lead. Lead is an important metal to which lately new theoretical interest has been attached, since there is actually reason to suppose, as has been briefly mentioned, that it represents the last stage of the atomic evolution, an earlier stage of which is represented by radium. The most important ore of lead is sulphide, the common name of which is *galena*. Commercial lead almost always contains a small proportion of silver, which is now extracted. When pure, the metal is very soft, yielding even to the finger-nail. It melts at the relatively low temperature of 334° C., and its alloys with tin are melted with similar ease. Lead is not attacked at all by dry air, but it is soon dulled by moist air, owing to the formation of an oxide. Lead, of course, is very largely used for the making of pipes and cisterns, and it is a matter of importance to know the conditions under which such lead will remain untouched, and the conditions under which portions of it will be dissolved and carried away in water which may subsequently be drunk. Comparatively large doses of the salts of this metal may be taken with entire impunity. Thus, acute lead poisoning is one of the rarest of occurrences, but the minutest quantities contained in water which is drunk for a long period, may give rise to chronic poisoning, which is unfortunately still exceedingly common, and very often fatal. Chronic lead poisoning also arises from carelessness on the part of workers in lead. The most important precaution which these workers can take is that of scrupulously washing the hands before eating. For obvious reasons, chronic lead poisoning is frequently referred to as "painter's colic." The carbonate of lead ($PbCO_3$, white lead), is one of the commonest of pigments.

The Action of Water on Lead. Let us now carefully inquire into the conditions which determine the action of water on lead pipes and cisterns. Hard water, as it is called, will never cause lead poisoning, because it is incapable of dissolving any lead from the surfaces with which it comes in contact. Hard water always contains free calcium carbonate or calcium sulphate, as we saw in a previous chapter. It is only in the case of soft water that any danger of chronic lead poisoning through the water supply is to be anticipated. Such water usually contains certain organic acids which are derived from the soil, and which may be conveniently included under the general term of humic acid—from the Latin *humus*, the soil. These acids are capable of dissolving lead from pipes or cisterns, and thus giving rise to lead poisoning. Soft water is thus a source of constant danger if used for drinking. A useful little precaution is to allow the tap to run for a few seconds before water is drawn for drinking purposes.

The chief oxide of lead is known as litharge, which has the formula PbO. Another oxide, Pb_3O_4, is known as *red lead*, and is a scarlet powder, which may be obtained by heating litharge. It is used as a pigment, and in making flint glass. When acetic acid acts upon litharge we obtain a white powder, which is the acetate, and which, owing to its sweet taste, is known as *sugar of lead*. It has some small uses in medicine.

The Nitrogen Group of Elements. We must now pass to an important group of five elements—namely, *nitrogen*, *phosphorus*, *arsenic*, *antimony*, and *bismuth*. Not only do these form a distinct group from the chemical point of view, utterly diverse though they are in physical characters, but they also form a recognisable group in the resemblance between their respective actions upon the human body. Much of the most important of these elements is nitrogen, which constitutes about four-fifths of the air, and which must be dealt with in detail.

Nitrogen. *Nitrogen* is a colourless, odourless gas. We inhale it with every breath. It may be obtained in a relatively pure state by several means. For instance, if we pass a current of air through a glass tube filled with red-hot copper, the copper keeps the oxygen while the nitrogen passes on; or we may turn out nitrogen from one of its most familiar compounds, *ammonia*, by means of chlorine. Ammonia has the formula NH_3, and if we pass a current of chlorine through a strong solution of ammonia, the hydrogen combines with the chlorine to form hydrochloric acid, HCl; whilst the nitrogen escapes, and may easily be collected. Other processes also permit of the collection of this element in a pure state from the compounds known as nitrates, which occur abundantly in many parts of the earth. Nitrogen may also be obtained from the complicated organic bodies called proteids. This element is a constituent of protoplasm—the physical basis of life—and therefore occurs in every living thing, whether animal or vegetable, high or low. In marked contrast to its partner oxygen, nitrogen is a very inert substance, having little tendency to combine with other elements. It is scarcely necessary to say that it does not support life or combustion. Its most useful rôle in the atmosphere, according to our present knowledge, is that of diluting the oxygen. Nitrogen is peculiarly insoluble in water. Under suitable conditions it can be burnt or combined with oxygen. Such union occurs as the result of passing an electric spark through the air, and thus—owing to the electrical conditions of the atmosphere, the passage of lightning, and so forth—small proportions of these compounds are found in the atmosphere. The oxides of nitrogen are no less than five in number—as we said in a previous chapter—but of these only one need be further discussed here, and that is known as nitrous oxide, having the formula N_2O. Popularly, it is called *laughing-gas*, and it is of historic interest as the first substance used for the production of general anæsthesia for surgical operations. Its property depends upon its behaviour in relation to the hæmoglobin of the blood, with which it forms a loose compound. It is probable that no single case of death directly attributable to its use can be recorded. It has a faint odour, with which the reader is very likely familiar. Very different is the odour of some of the higher oxides of nitrogen, which cause extreme discomfort and choking.

Phosphorus. This element and the succeeding two in this group, *arsenic* and *antimony*, are often known as *metalloids*, since they have at least some of the properties which we usually associate with metals. There is no free phosphorus in Nature, but the element is found in many rocks and minerals, besides being the necessary ingredient of all but the very lowliest forms of protoplasm or living matter. The element is usually obtained by distilling phosphoric acid (which has the formula H_3PO_4) with carbon. When this mixture is heated to whiteness the phosphorus distils over, and is collected in warm water. The manufacture is not easy, for the element is very ready to unite with oxygen, and burns, forming offensive and dangerous white fumes; thus the element has to be preserved under water. If any moisture be present, phosphorus is phosphorescent, or luminous, in the dark, the cause of this phenomenon being the slow oxidation which occurs on its surface. This ordinary, or *yellow* phosphorus occurs in eight-sided crystals; but we have here another case of allotropy, for if ordinary phosphorus be heated beyond a certain temperature in a closed vessel, or be heated in a tube with a small quantity of iodine, it is converted into another form called *red* phosphorus, usually called amorphous phosphorus, since it is usually non-crystalline. Red phosphorus is not luminous in the dark, since it is not oxidised at ordinary temperatures; it does not catch fire at low temperatures, it is exceedingly insoluble, and in consequence it is quite non-poisonous, whereas ordinary phosphorus is a very dangerous poison, the limit of safety for a medicinal dose being estimated at about one-twentieth of a grain. The most important commercial use of phosphorus is in the manufacture of matches, the chief value of the element in this connection lying in the fact that it catches fire at low temperatures. The ordinary match has phosphorus on its tip; in the case of the safety-match phosphorus is placed on the box. Recent inquiries seem to show that phosphorus may be obtained in a non-poisonous form which is quite efficient for all the purposes of matches. As very substantial danger is attached to the manufacture of matches in which ordinary phosphorus is employed, it is to be hoped that the manufacture of such matches, being superfluous, will shortly cease.

The Oxides of Phosphorus. Phosphorus forms two oxides, which have the respective formulas P_2O_3 and P_2O_5. Like CO_2, each of these is an anhydride of an acid. We need not here go into details of the various acids compounded of hydrogen, phosphorus, and oxygen. Hypophosphorous acid most people have heard of by implication, since its salts—the hypophosphites—have a probably illusory reputation as tonics. The most important acid is known as phosphoric acid, and has the formula already stated. Its anhydride is P_2O_5, which has a great affinity for water, and is used in chemistry for the purpose of removing the last traces of water from substances which are required to be absolutely dry. The reader may be puzzled as to how it is that the anhydride of the acid contains more atoms of oxygen than the acid itself, which certainly looks absurd. In order to solve this difficulty, we must double the formula of phosphoric acid, so that it reads $H_6P_2O_8$. If from this we take three molecules of water, we find that we have P_2O_5 left, according to the equation

$$H_6P_2O_8 = 3H_2O + P_2O_5.$$

The most important salt of phosphoric acid is one of the calcium salts. This phosphate of lime is an essential constituent of plants, and it is absolutely necessary to add it to the soil by one means or another if it is expected to have a continuance of good crops.

Arsenic. This element is occasionally found in the uncombined state, but more usually in the form of a sulphide, often in combination with sulphide of iron. It is most commonly prepared from the mineral known as *mispickel*, which is a combination of these two sulphides. When this ore is heated in earthen vessels, the arsenic comes over in a gaseous state, and can be condensed. Arsenic does not occur in the liquid state, but passes directly from the gaseous to the solid state. It is a steelish grey solid, and is another example of allotropy. If formed by slow condensation, it has a metallic lustre, and is crystalline. If rapidly condensed on a cold surface, it occurs as a black amorphous substance. The reason why arsenic does not liquefy is that, under ordinary conditions, its boiling point is at a lower temperature than its melting point. But if the atmospheric pressure be raised, the boiling point is raised above the melting point, and then the element may be liquefied. Arsenic is used in the manufacture of shot, as it makes the lead harder, and also makes it more readily assume a spherical shape as it drops through the air, which is the process by which shot is made. Arsenic is very largely used in medicine in very minute doses, and there are certain conditions of the skin and other organs in which it is extremely valuable. The great student of drugs, Binz, of Bonn, in Germany, has suggested that it owes its virtues to the property of carrying oxygen from the blood to the tissues. The drug accumulates in the body, however, and must not be given continuously. In large doses, and in chronic poisoning, arsenic causes a series of toxic symptoms, which resemble those caused by phosphorus, its predecessor in this group, and by antimony, its successor.

Antimony. This element is, perhaps, more closely allied to the metals than its predecessors. It occurs in nature in the form of the sulphide, which has the formula Sb_2S_3. Pure antimony can readily be obtained from the sulphide by heating this ore with scrap-iron, which combines with the sulphur, whilst the antimony melts and may be collected from the bottom of the vessel in which the operation is conducted. This element is brittle, bluish white, and crystalline, and melts at the comparatively low temperature of about 450° C. It is only acted upon by air when heated, and then forms the trioxide which has the formula Sb_2O_3, corresponding to that of the sulphide. Alloyed with lead, antimony goes to form *type-metal*. Alloyed with lead and tin, it forms Britannia metal. The introduction of this drug into medicine is usually attributed, as we remarked in our first lesson, to Paracelsus, and the story goes—but we give it only for what it is worth—that the derivation of the name depends upon a certain occasion when he took the opportunity of experimenting with this drug on a community of monks, who were very much disturbed by its unpleasant properties. Hence the name *anti*, against, and *moine*, the French for monk. This element is very much less frequently used in medicine nowadays than formerly. It has a direct antagonism to living matter, and is thus ranked, together with some other substances, such as prussic acid, as a *protoplasmic poison*. Its most characteristic action upon the human body is as an emetic, and its most familiar salt is the compound with tartaric acid, which is known as *tartar-emetic*.

Bismuth. Bismuth is the last metal of this group with which we have to deal. Reference to the table already given will show the reader that we have been dealing with these substances in the order of their atomic weight. Bismuth is exceedingly heavy, its atomic weight being no less than 208. It is prepared from its sulphide in a similar fashion to antimony. This salt occurs in Cornwall, whilst the metal is found native in Saxony. It is of some use in the formation of alloys, for when mixed with lead and tin, and sometimes with cadmium, it forms an alloy which melts considerably below the temperature of boiling water, and which expands when it solidifies. This is known as *fusible metal*. Bismuth forms a couple of oxides BiO_3 and BiO_5, and from these there may be formed salts which are of no particular importance. Two salts of bismuth, however, of no particular interest to the chemist, are largely used in medicine. These are the carbonate and the subnitrate, of which the latter is much the most important. In the treatment of certain affections of the alimentary canal, the subnitrate has no equal. It owes its medicinal properties partly to its weight and its consistence, but chiefly to the fact that it gives off minute quantities of nitric acid just where they are wanted, and is thus indirectly a safe, but powerful antiseptic. Commercial bismuth used to contain arsenic and may also contain traces of the rare metals *selenium* and *tellurium*, the latter of which sometimes imparts an unpleasant odour to the breath. Most pharmacopœias contain a large number of preparations of bismuth, including a number of liquid preparations, which are supposed to act more quickly; but as a matter of fact, these liquid preparations undergo change immediately after they are swallowed, insoluble salts of bismuth being at once thrown down, or *precipitated*, as chemists say. There is thus no reason whatever for preferring them.

We appear to have gone very far indeed from nitrogen, which was the first member of this group; nevertheless, the further we study the chemical and physical and physiological properties of these five elements, the more we are convinced that there must be a relation between them, the nature of which can be guessed in some measure by those who have studied the previous chapters of this course.

BITUMINOUS SUBSTANCES

Tar. *Tar* is the product of the destructive distillation of organic matter. As commercial products there are two principal classes of tar in use: (1) *Wood tar*, the product of the special distillation of several varieties of wood, and (2) *coal tar*, which is primarily a by-product of the distillation of coal in the manufacture of illuminating gases.

Stockholm Tar. *Stockholm tar*, known also as *wood tar* and *Archangel tar*, is prepared principally in the pine forests of central and northern Russia, Finland and Sweden. The material chiefly employed is the resinous stools and roots of the Scotch fir (*Pinus Sylvestris*) and the Siberian larch (*Larix Sibirica*), with other less common fir-tree roots. A large amount of tar is also prepared from the roots of the swamp pine (*Pinus Australis*) in North and South Carolina, Georgia, and Alabama, in the United States. Wood tar is a semi-fluid substance of a dark brown to black colour, with a powerful odour.

The ancient and crude method of obtaining tar is still largely adopted in the North of Europe. The wood to be treated is closely piled up into a huge conical stack or pile on an elevated platform, the sole of which is covered with clay and tiles. The sole slopes inwards from every side to the centre, where an opening communicates with a vaulted cavity under the platform. The pile is closely covered over with layers of turf and earth or sand, to a depth of several inches, leaving near the bottom numerous apertures to admit air to promote ignition. The pile is ignited from below, and as the fire spreads through the heap the various apertures are closed up. About ten days after ignition, tar first begins to flow, and it is at once collected in barrels. In this method several valuable products—the gas, the crude pyroligneous acid, and much charcoal—are lost or wasted, and a more economical process of treating the wood in closed stills or retorts is now largely used in Russia, the gas evolved serving as fuel under the retorts. The heavier tar products of the distillation collect at the bottom of the retort, whence they are carried off by a pipe to a receiver, and the volatile portion passes off at the upper part of the retort, where it is separately condensed.

Wood tar is most largely used as a protective coating for woodwork and other materials much exposed to water and the weather; it is thus of great value in connection with shipping and shipbuilding. A considerable quantity is used in manufacturing tarred ropes and coal-sacks.

Coal Tar. The art of distilling coal for the production of tar was discovered and patented by the Earl of Dundonald in 1787, and till the general introduction of coal gas some amount of coal was yearly distilled in Scotland for the production of coal tar. With the extensive use of coal gas the necessity for this separate distillation ceased, and soon tar was produced in the manufacture of gas in quantities that could not be disposed of. It was burned up for heating gas-retorts, mixed with coal-dust, sawdust, etc., for making patent fuel, and it was distilled for producing a series of hydrocarbon oils, heavy tar, and pitch, and it was only after the discovery of "tar-colours" that the substance came to be valuable; but even now the supply is greatly in excess of the demand.

Pitch. *Pitch* is a thick, tenacious substance, hard when cold, the residuum of tar after its volatile elements have been expelled; it is also obtained from the residues of distilled turpentine. It is manufactured mostly in tar-producing countries, especially Russia, and is largely used to cover the seams of vessels after caulking; it is also used to protect wood from the effect of moisture. Pitch, also, is the basis of the Berlin black, or Brunswick black, used for coating cast-iron goods and for "japanning" preparations.

Creosote. *Creosote* is a product of the distillation of wood tar, more especially that made from beech wood. The distillation of the tar is carried on till only a thick, pitchy substance is left. From the lowest layer of the distillate is obtained, by the action of sodium carbonate, a yellowish oil, the heavier part of which is isolated by rectification in a glass retort and mixed with potash solution to dissolve out its creosote. The creosote is separated from the filtered potash solution by sulphuric acid, is distilled with alkaline water, and again treated with potash and acid, till its purification is effected; it is then distilled at 392° Fahr. and dried by means of calcium chloride. The so-called *coal-tar creosote* is more or less impure carbolic acid, containing paracresol, and other bodies. Creosote has a strong odour and burns with a smoky flame. It has a specific gravity of 1·037. It has been used in surgery and medicine as an antiseptic with great success, but it is now almost superseded by the cheaper and equally efficient carbolic acid. It is also employed for preserving timber from dry-rot and other decay, and for the curing of fish and ham.

Carbolic Acid. *Carbolic acid* (C_6H_5OH) is a substance found in the heavy oil of coal tar, which distils off between the temperatures of 329° and 374° Fahr. When pure, it is colourless and crystallised into needles, which have a burning taste and smell, somewhat like creosote. If taken in large doses it is a poison, but, in small doses, it may be taken internally as a healing agent. Its chief use is as a disinfectant in surgery and as an external application to exposed tissues to exclude or destroy germs. It is the basis of many of the disinfecting compounds of commerce.

Asphalte. *Asphalte*, *Asphaltum*, or *mineral pitch*, so called from the Lacus Asphaltites, or Dead Sea, where it was found in ancient times, is a product of the decomposition of vegetable and animal substances. It is usually found of a black or brownish-black colour, externally not unlike coal, but it varies in consistency from a bright pitchy condition, with a sharp conchoidal fracture to thick viscid masses of mineral tar. Asphaltic deposits exist widely diffused throughout the world, more especially in tropical and sub-tropical regions. It is found in a state of great purity in the interstices of the older rocks, but its occurrence is not characteristic of any particular formation or period. The most remarkable deposit exists in Trinidad, where it forms a lake 99 acres in extent, and of unknown depth, intersected with rivulets of water. In addition to the lake deposit, asphalte occurs in the surrounding country in detached patches, or in sheets of considerable size, and pieces of asphalte are frequently cast up on the neighbouring shores by the sea. A considerable quantity of a fine asphalte is also derived from Cuba, under the name *Chapapote*, or *Mexican asphalte*; and from Peru a very pure variety of high lustre is exported. It occurs in many localities throughout Europe, but not to any considerable extent.

Of greater importance industrially than simple asphalte is asphalte stone—a limestone impregnated with bituminous matter, which occurs in large quantities in several parts of Europe. The most valuable deposits are in the Val de Travers canton of Neufchatel; in the neighbourhood of Seyssel, in France; at Bechelbronn, in Alsace; at Limmer, near the city of Hanover; and at Hölle, in Ditmarschin, etc. Asphalte is now used to an enormous extent in the construction of paving, of which there are two principal methods—first, the mastic process; and secondly, by the hot compressed process.

An artificial asphalte is prepared by boiling up the pitch of gas tar with chalk and sand; but such a substitute, though much cheaper, has not the durability of the natural compound.

Petroleum, or Petrol. The word petroleum is used to designate the forms of bitumen that are of an oily consistence. It passes, by insensible gradations, into the volatile and ethereal *naphthas* on the one hand and the semi-fluid *malthas* or *mineral tars* on the other. It is of great economical importance, especially as a source of light, occurring naturally oozing from crevices in rocks, or floating on the surface of water; and also obtained in very large quantities in various parts of the world by boring into the rock, whence it is termed *rock oil*. By far the largest quantity of oil is obtained from the oil-fields of America. The only other oil-producing region in the world at all comparing with those of the United States is at and near Baku, on the Caspian, where the existence of oil has been known from time immemorial, but where its commercial importance has only recently been realised. It may be said that petroleum has obtained universal diffusion as a lighting agent; it is fast displacing animal and vegetable oils as a lubricator on all classes of bearings, and also where other oils are liable to spontaneous combustion. It is very largely used as fuel for stoves, both for heating and cooking; and it is very successfully used for motor driving purposes. It has also become a useful substance to the apothecary as petroleum jelly or vaseline.

Gasolene. *Gasolene*, or *Gasoline*, is produced by the distillation of petroleum, and is the lightest volatile liquid obtainable. It is used for saturating gas or air in carburetters, and also in vapour-stoves.

Kerosene. *Kerosene* is a product of the distillation of petroleum, coal, bitumen, etc., and consists of a mixture of liquid hydrocarbons. It is practically the same as English paraffin oil, and often goes under the name of mineral oil, or American paraffin oil. It is extensively used in all parts of the world as an illuminating fluid.

Naphtha. The *naphta* known to the ancients was a fluid variety of bitumen, but the more modern *naphtha* is a colourless, artificial liquid obtained by the distillation of crude petroleum. Owing to its cheapness, it is largely used as a solvent in place of benzol and turpentine, for which purpose it forms a substitute often superior to the oil it displaces. It is also used extensively in the manufacture of paints, varnishes, rubber goods, etc., as well as by dyers and cleaners. Naphtha lamps are also used for temporary street lighting; and in vapour-stoves the variety of naphtha known as *stove-gasoline* is used for cooking purposes.

Shale Oil is the name applied in the trade to a certain quality of naphtha.

Benzine. *Benzine*, or *Benzin*, is a colourless liquid consisting of a mixture of volatile hydrocarbons, and obtained by the distillation of petroleum. It is used chiefly as a solvent for fats, resins, etc., and for cleaning fabrics.

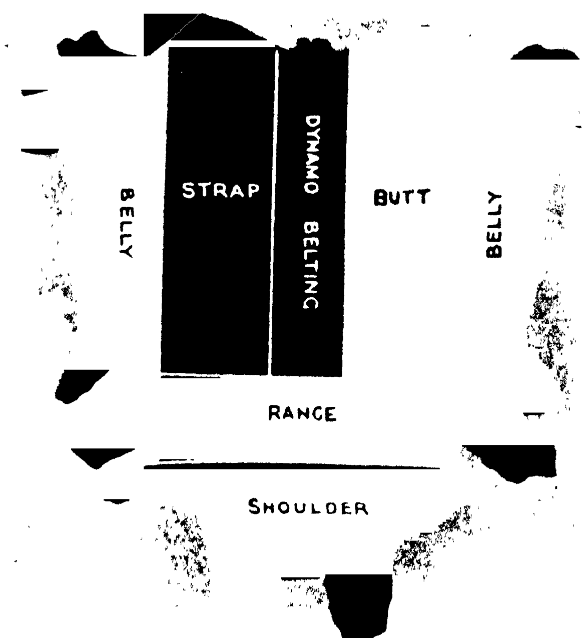
Benzol. *Benzol*, or *Benzene*, which is confounded with benzine, is essentially different from the latter, being a single hydrocarbon of constant composition, while benzine is a mixture of hydrocarbons. To confuse the two further, the colours are the same, and they are both used as solvents.

Paraffin. *Paraffin* is a tasteless, inodorous, fatty matter, obtained by the dry distillation of wood, peat, bituminous coal, etc. It gets its name from the Latin *parum affinis* (little akin) because of its indifference to all reagents. It is largely used for making candles and also as a waterproofing material for fabrics and paper. Other uses are—insulating for electrical work, polishing in laundry work, coating the surface of fruits and vegetables as a preservative, etc. One of the main sources of the paraffin supply is crude petroleum, which yields large quantities in its preparation for commercial use.

Ozokerite. *Ozokerite*, or *mineral wax*, is a mixture of natural paraffins found in the sandstones of the coal-measures. It is brownish-yellow, and in consistency not unlike resinous wax. In some parts it occurs in sufficient quantities to be used for various purposes, and also for making into candles.

LEATHER AND FIBROUS MATERIALS

Leather. *Leather* consists of the hides and skins of certain animals, prepared by chemical and mechanical means in such a manner as to resist influences to which in their natural condition they are subject, and also to give them certain entirely new properties and qualities. Skins in an unprepared, moist condition are readily disintegrated and destroyed by putrefaction, and if they are dried raw they become hard, horny and intractable. The aim of the leather manufacturer is directed principally to overcoming the tendency to putrefaction, to securing suppleness in the material, rendering it impervious to and unalterable by water, and increasing the strength of the skin and its power to resist wear. Leather is made by three processes, or with three classes of substances. Thus we have (1) *tanned leather*, in which the hides and skins are combined with tannin or tannic acid; (2) *tawed leather*, in which skins are prepared with mineral salts; (3) *shamoy leather*, consisting of skins treated with oils or fatty substances.



DIVISION OF THE HIDE

Reproduced by permission of James Dawson & Son, Ltd., Lincoln

Tanned Leather. The skins of all mammalians may be made into leather, but in practice it is only from a few of the larger animals, readily obtainable in sufficient numbers and reared and slaughtered for other objects, that commercial supplies are obtained. Of all hides and skins used by the tanner by far the most important and valuable are those obtained from oxen, but of late years horse hides and the skins of the ass, zebra, etc., have become important raw materials of leather, while sheep and goat skins are also very extensively used.

Leather is very largely used in the manufacture of boots and shoes, portmanteaus and hand-bags, machine-belting, harness, hydraulic cup leathers and fire-hose. The whole skin of the ox is divided out into parts according to its thickness and quality, the thickest being used for shoe soles and heavy belting.

Tanning. The actual process of tanning is as follows. The hides, after being prepared, are exposed in a series of pits containing *oozes*. As they are moved from pit to pit of the series the liquid through which they pass contains an ever-increasing strength of tannin until the last pit is reached, when the actual process of colouring or dyeing is completed. The hides are next spread out horizontally in piles in the handling pits and *handled*, or lifted with a tanner's hook at intervals, the one taken out from the bottom of a pile being returned on the top, and so on, this operation lasting about six weeks. The hides are then taken to the *lay-aways* and there exposed to the strongest tannin for a considerable period; then the pits are cleared out, the liquid drained off, and fresh liquid brought in, the operation being repeated three or four times, until the tanning is completed, and the hides are converted into leather.

Tanning Materials. *Tannin*, or tannic acid, is abundantly found in almost all species of the vegetable world, but oak bark and mimosa bark are the chief sources of its production.

Oak Bark was formerly almost the only tanning material used by British tanners, and even now the best quality of heavy goods are prepared by this method. Sole leather prepared by the bark of the English oak is very firm and solid, while other varieties of leather are soft, as for instance, some kinds of French leather prepared from the bark of the evergreen oak. The cork oak (*Quercus suber*), found in the South of Europe, possesses, in addition to its cork, an inner bark, very rich in tannin.

Mimosa bark is obtained from Australasia, from a large number of trees of the *acacia* species. Large quantities of this bark are imported into England, and some of it is very rich in tannin.

Other varieties of bark, producing tannin, are hemlock bark, Scotch fir, and larch barks, willow barks, etc., but these are not extensively used by English tanners.

Tawed Leather. *Tawing* is the term applied to the preparation of leather by the action of mineral substances, such as alum or aluminous salts, on hides and skins. In former times, tawing was used for preparing heavy leather, as machine-belts, heavy gloves, etc., but the system is now almost solely applied to thin and light skins, as sheep, kids, and goats. A large number of white tawed sheepskins are used by perfumers as covers for the tops of bottles, but the most important use to which this system is applied are kid boots, shoes, and gloves, and all kinds of glacé leather.

Shamoy Leather. This method of preparing leather is perhaps the oldest system of all. It consists of impregnating hides and skins with fish oil, for which reason it is sometimes called oil leather; while, owing to the extensive use of deer skin in this system, the product is often known as buck or doe leather. The original name—shamoy—seems to have been derived from the use of chamois skins, while yet another name by which it is known in domestic use is wash-leather, due to the fact that it may be easily washed like a cloth.

Artificial Leather. Under the name of American cloth, large quantities of artificial leather are imported into this country. The most common varieties consist of a calico material, first covered with a thick paste to fill up the pores, and afterwards coated with a mixture of boiled linseed oil, dryers, and lampblack or other colouring matter. The surface is then smoothed and compressed on the calico by passing between metal rollers, and finally coated with copal varnish to produce the glossy finish. It is extensively used for covering chairs, lining tops of writing-tables and desks, and many other upholstery purposes.

Oil-cloth. *Oil-cloth*, or *oil floor-cloth*, consists of a thick canvas backing that was originally painted and ornamented with the brush, but now the designs are applied by means of hand-blocks, or rollers. The thick material has largely given place to linoleum, but a thinner kind is still used for bordering to floor carpets and rugs, and for covering stair-carpets.

Kamptulicon. *Kamptulicon* is a variety of floor-cloth manufactured from a preparation of indiarubber thoroughly mixed with ground cork, the mixture being effected by passing the ingredients repeatedly between grooved rollers. The preparation is next rolled out into sheets, generally over a backing of canvas, by passing through steam-heated rollers. Although indiarubber and cork are the best substances for its manufacture, they are expensive, and cheaper things, as sawdust, gutta-percha, ground leather, asphalte, tar, chalk, etc., have been used. Kamptulicon has practically been displaced by linoleum.

Linoleum. *Linoleum* is a variety of floor-covering made of a preparation of intimately mixed linseed oil and ground cork, spread in a layer over a sheet of canvas. The linseed oil is first boiled with litharge, as in making ordinary boiled oil, and next exposed to the influence of the air in thin films, so as to be thoroughly oxidised. This is done as follows. Sheets of calico are hung up over large open troughs, and the oil is allowed to flow evenly over the surfaces of these sheets, any drippings falling into the troughs. For several days this operation is carried on, until the film of oxidised oil is about half an inch thick, when the sheets are torn to pieces and passed through crushing rollers, which reduce the substance to a plastic mass. This is next placed in a close boiler heated by steam, together with the colouring pigment, and after being thoroughly mixed with "stirrers" it is run off and allowed to solidify into large slabs, which are then cut into blocks about as large as bricks. The cork used is first broken to pieces, then passed through a mill, which grinds it to a powder. The actual operation of manufacture then commences. The blocks of oxidised oil, together with the required amount of ground cork, are put into a kind of pug-mill, thoroughly mixed, and next cut into slices by a revolving knife. These thin sheets are next passed through a series of rollers heated by steam, to the last of which the mixture sticks, and has to be scraped off in the form of a fine powder. This is next spread evenly over the canvas and passed between more rollers, which consolidates the whole mass. The only remaining operation is a coat of paint on the back of the canvas to preserve it.

The best linoleum is inlaid. The pattern runs through the whole thickness instead of being printed on the surface, so that the pattern cannot wear off. It is dry and warm to the feet, and may now be had in carpet patterns. All these varieties of floor coverings, however, exclude the air from the floor boards, and make them more susceptible to dry-rot. There is, however, little danger, unless moist stagnant air reaches the boards from their under side.

Cork. *Cork* is the outer bark of the evergreen species of oak (*Quercus suber*) which flourishes in the South of Europe and North of Africa, more especially in Spain and Portugal. Year after year additional layers are added to the inside of the outer bark until it becomes a thick, soft mass, possessing peculiar elastic properties which give to cork its value. The trees are first stripped when they are about 20 years old, this first yield being called virgin cork. It is rough, has a woody texture, and is not of much use except for forming rustic work in conservatories and as a tanning substance. After the first stripping the bark is removed every eight or ten years, the quality improving with each stripping. Cork is used for many purposes, as bungs and stoppers for bottles, hat linings, artificial limbs, etc., while, owing to its light specific gravity and durability, it is almost universally used for making various life-saving appliances, as belts, jackets, buoys, and parts of lifeboats. In a granulated form it is largely used as a non-conducting filling for cold-storage.

Charcoal. *Charcoal* is the more or less impure variety of carbon obtained from animal and vegetable materials by heating to redness in a vessel which is nearly closed, the volatile matters being thus driven off.

Animal charcoal, also called *Bone-black*, is made by igniting bones, which have been boiled to remove fat, in closed vessels of earthenware or iron. It is used as a decolourising and filtering agent, and may be re-purified after use by treating with acids. Animal charcoal is used as a pigment, in the form of ivory black, and also as a manure for sour vegetable soils. *Wood charcoal* is a hard, brittle substance, with a clear ringing sound when struck, made from a large variety of trees, as oak, ash, birch, Scotch fir, elm, beech, chestnut, etc. It is used as a fuel, particularly in France, as a reducing agent in metallurgy, in the manufacture of filters, and in medicinal work. The use of charcoal filters for drinking water is now universally condemned, but there are other cases where it furnishes a suitable filtering medium.

Torgament. *Torgament* is the name given to a pasty material, composed of asbestos and other silicates, which is used as a permanent floor or wall covering. It sets into a hard, jointless surface, proof against dry-rot and damage by fire or water. It can be easily washed or cleansed, is very durable, does not crack, does not harbour dust, vermin, or bacteria, is impervious to rodents, and, from its hygienic advantages, is coming into use for hospitals and infirmaries. It may be waxed and polished, or left with a non-slipping surface, without altering its character. The colour may be varied as desired.

Stonuood flooring, and the *jointless sanitary flooring*, made by Messrs. Smith Brothers, are very similar to torgament.

PAPER

Paper consists of a thin, compact web of vegetable fibres artificially prepared and most largely used for writing and printing. The name is derived from the *Papyrus* plant of Egypt, whose leaves were used for writing upon before the invention of paper.

Writing and Printing Papers. Writing and printing papers of the best quality are made from rags, which are first cut into pieces about the size of the hand, then separated into linen and cotton of different qualities, and each lot placed in a separate receptacle, after being subjected to the *willow* and *duster* to knock out the dust. The rags are next placed in what is known as a *rag-boiler*, which is then half filled with water, and a quantity of caustic soda, varying with the nature of the rags, is added. After boiling for 10 or 12 hours they are washed with cold water and afterwards picked over to separate any impurities. The rags are next passed to the *breaking engine*, which cuts them into fragments, and a solution of chloride of lime is added for bleaching purposes, after which the pulp is run into large stone chests, where it is allowed to remain until quite white. It is then pressed to remove as much as possible of the bleaching solution. The bleached pulp is next passed to the *beating engine*, where it is washed to free it from any remaining solution, and then subjected to the beating operation, during which the loading material, such as pearl white or china clay, is added, except in the case of hand-made paper, when nothing is added. This addition of mineral matter weakens the paper to a certain extent, but it closes up the pores, so that it will take a better finish. The next operation is the sizing, consisting of a mixture of resin soap treated with alum, which forms a comparatively waterproof covering. If the paper is to be tinted, it is generally accomplished by the use of aniline colours, and all coloured papers are produced by the use of various pigments.

Hand-made Paper. *Hand-made paper*, so far as the manufacture of the pulp is concerned, is done in the same way as writing and printing paper just described. The wet pulp is then spread evenly over a mould of fine wirecloth, through which the moisture drains, leaving the dry pulp. This is then turned over on to a sheet of felt, and the operation repeated until the required number of layers of pulp between felt sheets are obtained. They are then placed in a pile and taken to a press, which presses out the greater part of the remaining water, leaving the paper sufficiently dry to be handled. The sheets are then parted and each separately re-pressed, after which they are hung up in spurs of three or five sheets to dry. The spurs are next passed through a trough containing the sizing material, which is a strong solution of gelatin, and sent between rollers on an endless band of felt to take off the superfluous size, and the sheets are then carefully parted, to prevent sticking, and again dried. They are then packed and glazed between plates, and afterwards sorted and finished in the same way as other paper, only with more care

Blotting Paper. *Blotting paper* is a coarse, unsized paper of a spongy character, used for absorbing the superfluous ink from freshly written paper Lithograph and multiplex copying papers and many printing papers are more or less of the same character, as they then take printing ink better, which is not liable to run as writing ink would do.

Esparto Paper. Although all the better qualities of paper are made from rags, the demand for material is so large that other sources of supply have to be tapped for the cheaper qualities of paper, and perhaps the first among these is *esparto*. The grass is first sorted and then boiled in the same way as rags, but with a more liberal proportion of caustic soda. The rest of the operation of manufacture differs very little from that of rags, more bleaching solution being required, and the resulting paper is of a more bulky nature, admirably suited for printing purposes.

Straw Paper. A large quantity of straw is used in England and America for paper-making, but it is usually mixed with either rags or esparto, as it is too brittle to use alone. It is first dusted, then in many cases cut into chaff, and boiled under high pressure with caustic soda, after which it is washed and bleached in the usual manner.

Wood Paper. Wood is another material that is largely used in the manufacture of paper. The wood selected is generally poplar or white pine. This is cut into slabs, which, by one process, are pressed against a mill-stone running at high speed, the fibres as they are separated being taken away, sorted according to fineness, and pressed into pulp or half stuff, which is sometimes made into paper alone, but it is more often used as an admixture for making inferior paper. There are also other ways of preparing the wood in a chemical manner. The wood is also prepared by being fed against revolving steel cutters, which reduce it to small chips ready for maceration into pulp.

Brown Paper. *Brown paper* is the general name applied to wrapping papers of all qualities and materials that are of a brown colour. The coarser varieties are made from old rope or unbleached manila and used for all kinds of wrapping purposes. When painted over with boiled linseed oil it makes a useful packing paper for machinery.

Wallpaper. *Wallpaper* is the mural decoration most generally used at the present time, and takes the place of the more costly textile hangings of earlier times. Wallpaper dates back to the sixteenth century, but it did not come into general use until the eighteenth century, while of late years well-known designers have devoted their sole attention to the subject, with the result that many splendid varieties are now produced.

The best wallpapers are printed by hand from wooden blocks upon which the pattern is cut, the outlines being formed of brass or copper strips set edgeways in the wood, requiring a separate block for each colour.

The cheaper kinds of wallpaper are produced by machinery, the pattern being printed from rollers. The machine-made papers will scarcely bare comparison with hand-made papers, either for quality of tint or finish.

Stencilling. *Stencilling* is another, and, if not too elaborate, still cheaper method of decorating the plastered surfaces of walls and ceilings. The pattern is cut out of thin sheets of zinc or Bristol board, and so arranged that all the parts are held in position by small pieces called "ties," which are left in for the purpose. In the stencil the parts which are to appear in colour on the prepared surface are holes, while the parts to be left untouched on the surface are filled in solid on the stencil plate.

FIBRES IN GENERAL USE

For a full description of these materials reference must be made to the section on TEXTILES.

Hemp. *Hemp*, as known to commerce, is a tough, strong fibre obtained from the rind or skin of the hemp plant—by rotting the stalks under moisture—and afterwards prepared in various ways for use in manufacture It is extensively used for weaving into coarse fabrics such as sailcloth, and also for twisting into cables and ropes. The plant is a native of Central and Western Asia, and is largely cultivated in India, but it has also been introduced into parts of Africa and Brazil, and is extensively cultivated in many other countries.

Jute. *Jute* is the product of various plants of the *Corchorus* family, but the jute fibre of commerce is only produced by the two species, *C. capsularis* and *C. olitorius*, both of which are natives of Bengal. The fibre of the plant, which is glossy and capable of such fine division as to mix with silk, is obtained by maceration from the inner bark. It is largely used in Bengal for the manufacture of gunny bags, and is also used for making inferior ropes, but as it will not stand the moisture, jute ropes are not of much use. The refuse of jute may be made into a good quality paper.

Coco-nut Fibre. *Coco-nut fibre*, or *coir*, is the name given to the substance of the fibrous husk, or rind, surrounding the hard shells which enclose the coco-nuts, or fruit of the coco-nut palm. The coir or fibre is manufactured into matting, bags, brushes, etc. The refuse is used by horticulturists to cover the soil in carpet bedding, to protect bulbs from slugs, to pack between pots of cuttings, and for other purposes.

Rope. *Rope* is technically the name given to a cord over 1 inch in circumference, but the name is commonly applied to any thick cord. Smaller ropes are called *lines*. Ropes may be divided into two kinds: (1) Those made of hemp, manila, flax, cotton, and other fibre; and (2) those of iron, steel or other wire. Ordinary ropes are usually of hemp, and are composed of a number of threads or yarns, first spun into strands which are afterwards twisted or *laid* right-handed together to form the finished rope. Each rope has a different name, according to the number of strands it contains.

Flax. *Flax*, or *lint*, is the name employed to denote both the so-called fibre and the plant from which it is produced. The flax is really the remaining fibres of the stems of the plant after the superfluous matter has been removed by either one of the methods known as *water-retting* or rotting, and *dew-retting*, of which the former is the more widely used. The fibres, when produced, are used in the manufacture of linen cloth and thread, cambric, lace, etc.

Canvas. *Canvas* is a heavy woven cloth of hemp or flax fibres, used for any purpose where great strength is required—such, for instance, as sailcloth; and so extensively has it been used for this purpose that the term canvas in now often employed in speaking of the sails of ships. Originally, canvas was made from hemp, and the name is a corruption of *Cannabis*, which is the scientific name for the hemp plant; but the canvas made from linen or other fabrics is now generally preferred. Other purposes to which it is put are grounds for oil paintings, backing for linoleum, etc.

Cotton. *Cotton* is a white fibrous substance, the product of the cotton plants, *Gossypium barbadense*, or sea-island cotton, yielding fine, long staple or pile; the *G. herbaceum*, yielding the short staple or upland cotton of America; beside many other varieties. But of them all, the first mentioned is by far the most important in commerce, owing to the length of its fibres.

Cotton is used as the most widely adopted clothing material for the human race, in the manufacture of thread, and in surgery as a dressing for burns, etc.; while, when cotton is acted upon by nitric acid, it yields the powerful explosive known as guncotton.

Cotton-wool is a raw cotton or cotton fibre either on the boll or prepared for use. It is the well-known fluffy material used for many purposes. For surgical use, it is treated with an antiseptic and known as *medicated* wool.

Wool. *Wool* is a soft, curly hair which forms the coat of sheep and some other animals, as the Alpaca and Angora goat. The wool or fleece of sheep forms by far the most important clothing material in all cool climates, and it may be taken as the finest variety of the substance, as the coats of some animals run by almost imperceptible degreees from wool to hair. When shorn, wool is divided into two classes—*long*, or *combing wool*, and *short*, or *carding wool*—which latter seldom exceeds 3 in. or 4 in. long and produces the finer varieties, while the long staple makes the coarser kinds. The wools, *carding* and *combing*, obtain their names from the manner in which they are worked—the former being worked on a carding machine, while the latter is prepared for spinning by combing.

Cloth. *Cloth* is a fabric formed by weaving threads of cotton, hemp, flax, or other vegetable fibre, or a texture of hair or wool. It is used for making clothing, and coverings of all kinds, as well as for many purposes too numerous to mention here.

Felt. *Felt* is an unwoven fabric of short hair, wool, or fur, the fibres being matted together by a kind of mutual adhesion. The hairs which contain the best felting properties are mohair, alpaca, camel hair, beaver hair, and rabbit hair, the last mentioned especially supplying the finer felts used for hat-making.

Lining felt as used in building, is a coarse felt placed between two layers of boards or on the inner surface of walls as a non-conductor of heat and also to deaden sound. A similar fabric, made of asbestos and hair, sometimes mixed with a lime cement, is used as a non-conducting covering for boilers and steam pipes, and there are many other varieties of coverings for the purpose based upon the same general principles.

Roofing Felt. *Roofing felt* is a somewhat similar material to lining felt, used for covering roofs. It is not a true felt, but a mixture of hair or other animal fibre compounded with a tar preparation, and rolled into sheets, which are nailed in the required position, and, if not otherwise covered, they are then coated with tar and sanded to hold the tar when exposed to the sun's rays.

Ruberoid is a roofing felt, saturated and coated with a patent compound which is said to be non-oxidising, water-, acid-, alkali-, and weather-proof. Its foundation is wool felt, and although it looks like millboard covered with rubber, having a smooth or slightly ribbed surface, the makers state that no paper is used in the manufacture, and that it contains no tar, pitch, rubber, asphalte, or other short-lived ingredients. It is used as a sarking felt, an external roof covering, and as a damp-proof course in walls.

Impregnated Foundation Felt. This is another wool felt material, prepared in various thicknesses, for insertion under machinery foundations to prevent vibration and deaden sound, and may be used under floors as a non-conductor. It is durable, resilient, weather-proof, and fire-resisting.

SUNDRY MATERIALS

Dextrine. *Dextrine*, also called starch gum, and gommeline, is a white gummy substance of the same composition as starch. It is largely used in the arts and medicinal work as a substitute for gum arabic.

Alabaster. *Alabaster* is a mineral, not unlike marble, of a colour varying through shades of red, yellow and grey; but the most valuable varieties are pure white, as, for example, that found in Italy, near Florence. There are two distinct kinds of alabaster—(1) the gypseous or granular variety, or sulphate of lime; and (2) the calcareous variety, or carbonate of calcium, which was the alabaster used in ancient times. Alabaster, being soft, can be turned with a lathe or carved with a knife, and is largely used for making vases, statuettes, and other small works of art.

Blue-John. This is the local name given in Derbyshire to a blue variety of fluorspar. The name was first applied by the miners who discovered it, in order to distinguish it from the ore of zinc, known as *Black Jack*.

Blue-Billy. This is the name applied to the residuum of pyrites after the manufacture of sulphuric acid or sulphur has been carried out. It is largely used for repairing puddling furnaces in some parts of the country. This name is also given to the quicklime removed from gas purifiers.

SCAFFOLDING, STAGING AND GANTRIES

The Various Systems Employed for Different Purposes. External and Internal Platforms. Piling and Strutting. Derrick Stagings

By Professor R. ELSEY SMITH and W. HORNER

SCAFFOLDING

Before any building has been raised far above the ground level, the work will be out of reach of a man standing on the ground, who cannot do satisfactory work at a level of more than 5 ft. at the outside above the ground upon which he stands. Platforms must be erected at successive heights as the building grows, that work may be carried on and material for immediate use may be stored. The term *scaffold* is applied to such platforms and the framework arranged to carry them.

A Bricklayers' Scaffold. A bricklayers' scaffold [62] consists in this country of a temporary framework of circular fir poles of various sizes and lengths, which are lashed together with cords of hemp or of galvanised iron wire. This lashing is termed *tying*. The average size of a pole may be taken to be about 5 in. in diameter, with a length of 30 ft. The frame of the scaffold is formed with a series of vertical posts, termed *standards*. These are placed about 8 ft. apart, and at a distance of 4 to 5 ft. from the face of the wall. The foot of each standard is, if circumstances permit, imbedded for about 2 ft. in the ground; but if it is to stand on a pavement, as in a street, it may be placed in a large tub filled with earth, or, when in position, may be surrounded with a mass of concrete, the object in either case being to keep the foot from shifting.

For scaffolds of moderate height each standard consists of a single pole, and may be extended upwards by lashing another pole to it. Where a lofty scaffold is to be erected, the standards may be formed throughout of two poles of unequal length lashed side by side, so that, when extended upwards, the poles will be jointed at different levels, thus breaking the position of the joints and rendering the work stiffer. The lashing of two such poles together is termed *marrying*.

Similar fir poles are placed horizontally against the standards and are securely lashed to them. These are termed *ledgers*. They are placed at intervals of 5 ft.—which distance is termed a scaffold height—right up to the highest level necessary for the building. To stiffen the structure thus formed, especially in exposed sites, poles are placed diagonally from the base of the scaffold to the top, and are lashed to both standards and ledgers to prevent any racking of the scaffold.

Erecting the Scaffold. In this way a light, strong frame is constructed parallel with the face of the wall to be built. It is not completed before the work starts, but grows with it, the height of standards being increased and additional ledgers added as required.

The lashing of the framework is carried out by means of scaffold cords (which are 8 ft. lengths of manilla rope whipped at both ends) twisted several times round the two poles to be united, whether they are at right angles or side by side. The scaffolder's principal tool consists of a special hammer with a spur projecting from it. In tying, the cord may be twisted round the handle, the head placed against the pole as a fulcrum, so as to draw the cord tight. The cords are fastened off by threading the ends under two or three turns. The hammer is also used for forcing the cord into position. When the lashing is completed, pointed wedges having one side flat and the other round are inserted between the pole and the cord, and driven in to tighten up the joint further and left in position. Such cords are liable to shrink in wet weather and to stretch again in hot, dry weather, and under such conditions the scaffold must be examined and the wedges tightened up.

The wire cords are not liable to be affected by weather in this way, and can, in most cases, be tied sufficiently tightly without employing wedges.

Platforms. The platforms are formed as follows: The brickwork having been carried up to the level of the top of the fresh ledger, small square timbers, termed *putlogs*, usually split out of birch, about 3 in. square and 5 ft. long, are laid about 4 ft. apart, one end resting for about 4 in. on the brick wall and the other end on the ledger, and some of them, at least, are secured to the ledger.

On these timbers *scaffold boards* are laid side by side: these are usually about 12 ft. long, 9 in. wide, and 1½ in. thick. The square corners are splayed, and the ends are protected with a strip of hoop-iron nailed to the board, which prevents them from splitting. To form working platforms these are laid side by side across the putlogs and the full width from the wall to the ledger, and the ends are butted one against the other. At such joints two putlogs are placed close together, each supporting the ends of one set of boards. Boards sometimes have the ends lapped, but this is not so good a method, and in no case should the end of any board be left without a support under it, or it may tip up if stepped upon and cause an accident. Along the outer edge vertical *guard boards*, to prevent materials falling off, are fixed, and at a height of 3 ft. 6 in. a rail is fixed for the protection of the workmen.

Runs. Runs may also be formed from one part of a scaffold to another, and should not be less than 18 in. wide. These are formed of two boards (or more) laid side by side, and they should be joined together by strips of wood nailed at intervals on the underside.

The lowest platform of all is left permanently in position, and, if next a street, must have a double layer of boarding to prevent dust and rubbish from falling through. The other stages are removed successively as the work proceeds, and are re-erected at a higher level.

The foreman must see that the scaffolder prepares each stage in advance of the bricklayers' requirements, so that there may be no delay. As the wall is built up from any stage, a half-brick is omitted, where the putlog rests on the wall. This is known as a *putlog hole*, and is filled in later as the scaffold is taken down. If the *pointing* [see BRICKLAYER] of the wall is left to the finish, the stages must be temporarily reinstated to execute this work, and the putlog holes are filled at the same time.

Internal Scaffold. The frame described is assumed to be placed on the outer side of the wall, but a similar frame and platforms must in many cases be erected on the inner side, otherwise the bricklayers would have to work on the inner face *overhand*—that is, by leaning over the wall to set the inner bricks, and such work is not capable of a finish equal to that executed in the ordinary manner. The inside scaffold is often slighter and less complete, and advantage may be taken of cross walls to support the ledgers.

Cross Bracing. In addition to the bracing already described in the plane of the framework, it is desirable wherever inner and outer frames are employed to tie them together.

This may be done where door and window openings occur, and contributes to the rigidity of the scaffold, and particularly in exposed situations helps to resist the action of the wind, which often tends to force the whole scaffold out of the perpendicular. On open sites poles may be erected in the form of raking struts to steady the outer scaffold when it cannot be tied to the inner one.

A Masons' Scaffold [63]. A masons' scaffold resembles a bricklayers' scaffold, but when a wall is built of large stones, there are no longer the facilities afforded by brickwork, of forming putlog holes to take the inner ends of the putlogs, and two frames are required, one usually about 5 ft. from the wall and the inner one about 6 in. only from it.

The materials to be dealt with are often much heavier than in the case of brickwork, and the standards may be placed nearer together and braced more rigidly to provide adequate support, and they must be secured so that there is no risk that they will lean away from the face of the wall.

The illustration [62] shows a scaffold suitable for the erection of a small building of considerable

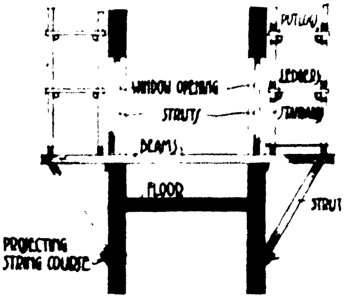
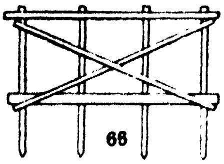
64. PROTECTING FAN



65. SECTION OF A SCAFFOLD ERECTED ABOUT A TOWER ABOVE THE GROUND LEVEL.

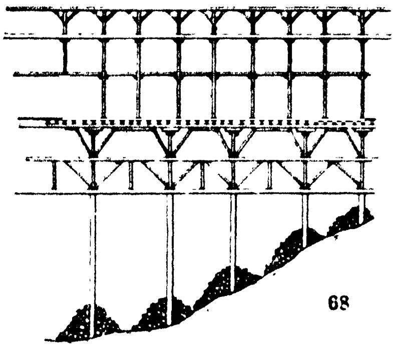
height, such as a detached sanitary tower of a *hospital.*

Ladders. Access to various parts of the scaffold is provided by ladders. They are made of various lengths, and are described by the number of rungs they possess. Very long ladders are often used for repairing and painting work, but in connection with scaffolding, ladders of moderate length are used. Where a great height has to be reached, several ladders are employed, and a platform is provided on which to land from each before climbing the next. The foot and head of each ladder must be firmly lashed or otherwise secured, and a strut is provided from the scaffold about the centre of the ladder to prevent oscillation.



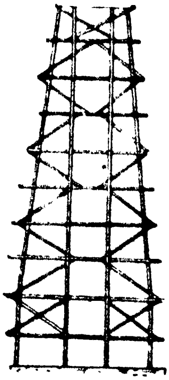
66

Hoisting Material. Materials are often carried up by labourers in hods or baskets. For larger buildings, the height of which is not great, a kind of well-hole or run is provided at some convenient spot, and lined with scaffold boards placed vertically to enclose it on two or three sides. Materials are hoisted in barrows or baskets by means of a pulley and windlass worked by hand or by a small engine. For large works one or more derrick cranes are used, and by their means materials can be hoisted from carts and deposited directly at any desired spot. Small materials such as bricks, are packed in crates and hoisted in bulk. Large stones, timbers, ironwork, etc., are dealt with separately, and great care must be taken to see that they are properly secured before they are lifted.



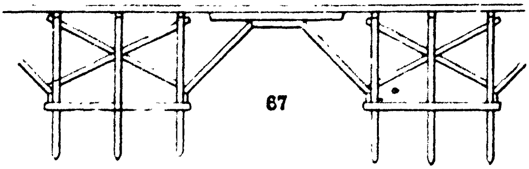
68

In executing repairs, a scaffold may sometimes be erected round the upper part of a building without being built up from the ground. In the case of a tower, for example [65], strong beams may be passed through any suitable opening, extending from side to side of the tower so that the load on the two ends will counterbalance and form a base on which a scaffold may be constructed. The outer ends of these timbers may often be strutted from a projecting string course at a lower level. Where the beam cannot or is not required to pass right through the building, the inner end must be secured against any tendency to tilt up by being strutted against an upper floor.



69

Protecting Fans. Where such work has to be executed adjoining a public thoroughfare, and where old buildings are being pulled down, wooden fans are aften formed for the protection of the public [64]. They are constructed in the manner just indicated; bearers are passed through the available window openings but are not placed horizontally as for a scaffold, but inclined upwards, and the inner ends are securely fixed. The outer ends are covered with boards or cross bearers, and are placed, if required, to receive the close boarding. Various forms of patent standards for scaffolding and extending scaffolds are to be hired or purchased, and are useful for special forms of work, but the ordinary scaffold as above described remains in general use.



67

Sling Scaffolds. Sling scaffolds, or boats, are used especially for painters' work. They require a strong projecting beam fixed above the level at which work is to be executed. From this a small stage or platform, protected by rails and large enough for one or two workmen, is suspended by cords and pulleys, and can be raised and lowered at will. The cords and tackle used for hoisting such boats must be thoroughly examined periodically to see that they are in a perfectly sound condition.

STAGINGS AND GANTRIES

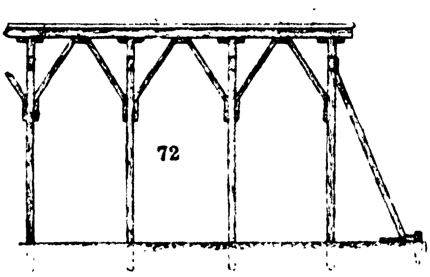
The bricklayers' scaffolding made of poles and ledgers, lashed together with ropes, and supporting putlogs and planks, have but a limited service in engineers' work, which is generally of so exacting and varied a character that something much more substantial is required. The stagings of the engineer are used for the erection of girder bridges, viaducts, steel roofs, piers, and allied work, taking the place of the centring of the bridges of stone and brickwork. The scaffolding of the engineer has to carry massive girders of steel, and often besides cranes and tackle for hoisting the same. These "temporary works," as they are called, are often constructed of steel, but with these we are not concerned. They are of rather a costly character, even though built of timber, because of the large quantity required and the labour engaged in their construction.

Gantries. There is also a type of staging better known under the term gantries, the functions of which may be identical with, or different from, the foregoing. Gantries are built for the erection of work simply, or they are structures for carrying travelling cranes, or erecting towers, or skips, etc. The difference in the two is rather in function than in essential form or design. In the case of many architectural works of a large and substantial character, especially when masonry is much used, various forms of gantries, including derrick platforms, are very generally employed.

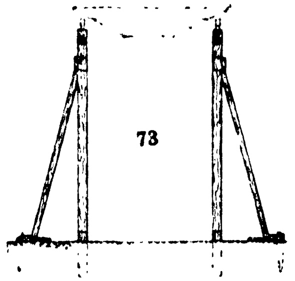
Trestles. Allied to these, again, are the trestles, or clusters of braced standards used for carrying horizontal staging, the timber staging for derrick cranes, the towers for aerial ropeways, all having this in common, the cross bracing of vertical members otherwise liable to bend and yield under loads.

Stagings, again, may be broadly divided in two groups—the fixed and the portable. The first is the more common, the second being used chiefly for the erection of bridges over deep streams into which piles cannot be driven. It is also employed in erecting gasholders.

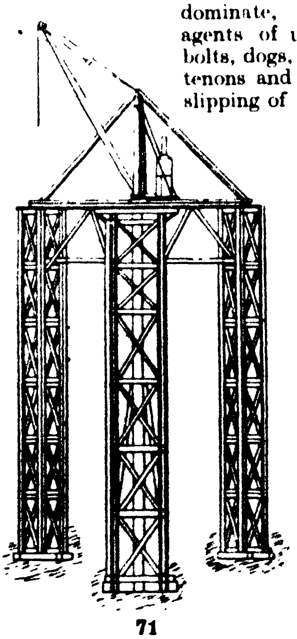
Methods of Union. One feature which all these structures have in common is the method of union of the timbers. As these consist of balks, mostly with some half timbers and plank decking, the fine work of the joiner is out of the question. The stub tenon and the joggle predominate, and the real agents of union are chiefly bolts, dogs, and spikes. The tenons and joggles prevent slipping of the timbers over one another, but their security depends on the bolt and other fastenings employed.



72

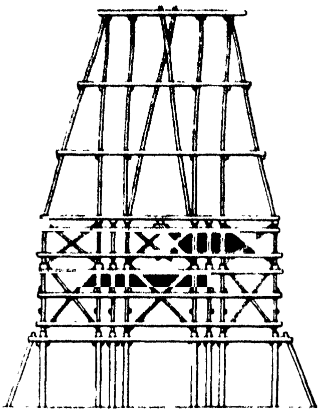


73



71

Bracing and Struts. Another essential characteristic is that bracings and struts enter largely into construction. The taller and longer the structures the more importance do these assume. It is a familiar fact that one diagonal brace will prevent a rectangular frame from "going cross-cornered"—in other words, assuming the form of a rhombus. This fact illustrates one of the functions of bracings and struttings. But another of equal importance is that bracing puts the tall standards into the condition of short columns. This means that the tall sticks of timber, even though, say, 12 in square, are very weak, and would bend and yield if unbraced, but when several of these are connected with diagonal bracings the strength becomes that of short columns of large area of base.



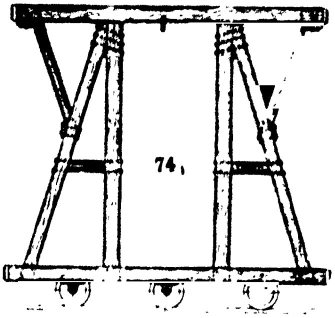
70

Fixed Stagings. Fixed stagings on land are built on squared timbers (balks) sunk into holes dug several feet deep in the ground, and loaded round with large stones. The ends are well tarred first. Similar stagings in streams or on dock sides, or on breakwater and pier work, are built on squared piles [**66** and **67**] shod with steel and driven into the soil. The real work lies here, since the difficulties are greater than with superstructural portions. Good piling is a firm foundation on which to build.

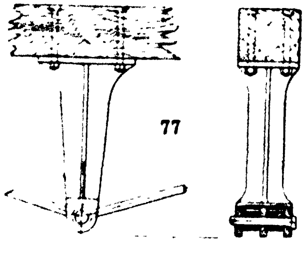
Piling. Piles are rendered capable of supporting a superincumbent load either by their reaching firm ground, or, when no such ground exists, by the friction of their sides against the soil. Much difference of opinion exists in regard to each of these, but when an ordinary monkey, let fall from its full height, fails to move a pile more than ⅛ in. or ¼ in., it is considered that the pile has found a firm bottom.

The spacing of the piles is settled by the load upon them. About 1,000 lb. per square inch of head is a safe load.

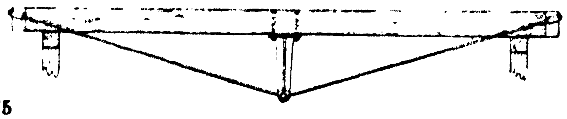
Stability is often studied by driving piles in diagonal directions instead of perpendicularly, imitating the batter of walls, and thus increasing the width of the base considerably. This can only be done in one direction as a rule, the



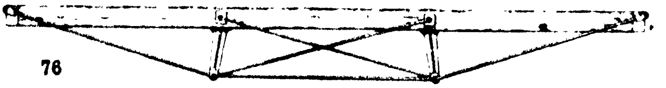
74



77



75



76

exception being a structure with a base of square or oblong form.

It is not sufficient to drive piles firmly ; they must be tied together in some way so as to enable them to withstand the rolling or rocking loads to which they will be subject. Piles are often tied together by straining chains with a tightening screw. The chains are attached to the piles which form the four corners of an enclosed rectangle, and are screwed up taut. Sometimes the fastening down of the cross timbers and decking are sufficient, but more often, especially in deep piling, the timbers have to be strutted [67 – 71] or connected with diagonal bolts crossing each other. It is not usual to place much reliance on bolt fastenings or on the end contact of timbers for stability, but to trust more to the judicious crossing and strutting, which prevent initial movements.

The uprights or standards of stagings erected on land [71—73] have the same functions as piles driven under water, and the remarks just made respecting tying them together and stiffening with struts or crossing bolts apply whether the stagings are fixed or mounted on wheels.

Strutting. The strutting of main timbers when done properly renders movement in any direction in the plane of the struts impossible. The strutting is made double, equal, and in opposite directions, for this purpose ; the stress tending to move the structure as on a pivot to right hand or left is met by its strut or set of struts. The struts must, therefore, be provided with some suitable resistance. Here it should be obvious that no mere tenoned joint would hold the members firmly. Though stub tenons are sometimes used to prevent slipping sideways, they are never relied on alone, but straining pieces, joggles, or abutment pieces, as they are variously termed [67, 68, 72, and 73], are employed. They may be long pieces bolted or spiked to the main timbers, or short chocks only, similarly fastened as shown in 72 and 73. These take the stresses on the struts, but the latter must be also bolted or dogged securely to the main timbers, the bolts passing through and their heads and nuts resting on iron washers. The dogs are simply driven in just as the carpenter drives his little dogs or staples temporarily into timber. Too many bolts in timbers are objectionable, not only because they cost more to make and fit than dogs, but also because the bolt-holes lessen the value of the timber for sale. This, of course, only applies to temporary works.

Horizontals. The upper horizontal timbers must be adequately supported. If the piling or the standards are not very far apart, the horizontal timbers generally require no other support. Frequently, however, two sets of horizontals are used, laid one over the other, crossing at right angles. But, apart from this device, horizontals must be stiffened if they are supported only at long intervals. This is done either by strutting [72], or by trussing [75 and 76]. The first named is less costly than the second. But when timbers are very long, trussing is the only method practicable, and this may be single [75] or double [76]. In this the stresses tending to bend the timber downwards are transmitted to the truss or tie-rods, which are anchored at the timber ends, and in a strut of cast iron [77], or two such struts, fastened to, and projecting from, the bottom face of the beam. This device is not often adopted in temporary stagings, but it is usual in permanent gantries.

Tall Stagings. Tall stagings [68, 69, and 70] are essentially a multiplication of the single staging. They are necessary where the girders for bridges and viaducts have to be carried across deep ravines. They are made broader at the base [69 and 70] than above, and the main members form several tiers, which are each strutted similarly to a single element. Around this general design engineers effect all kinds of modifications adapted to any particular piece of erection in hand.

Portable Stagings. Portable stagings embody the principles of construction of the foregoing in so far as the strutting and union of the members is concerned. The difference is that, instead of fixed piles or standards, the staging is mounted on flanged wheels [74], to run on rails, if on land, or is placed on a pontoon, or pontoons, if for bridge erection.

Bridge-erecting Stages. The stagings for the erection of bridges are of two kinds—those having the piles or standards spaced equally, and those in which they are clustered. The difference between the two is as follows.

Equal Spacing. Here the bridge is erected on stagings which are placed at regular intervals [68], excepting near the centre of the waterway, where a space of double or treble that allowed elsewhere is given, in order to permit of navigation there. But at any other locality the stagings bar traffic. This method is only suitable where streams are not liable to flood or to drifting ice. It is a simpler construction than the cluster device, but in some cases uses a larger quantity of timber.

The Cluster System. In this [69 and 70] navigation is scarcely impeded, since the clustered standards are spaced widely apart. But this involves the connection of the tops of the standards by horizontal beams, so making a gantry. These beams of timber or steel are generally both trussed and strutted, to enable them to carry cranes and the loads of the bridge girders.

The standards for staging must consist of piles in swift streams, and in those like the rivers of Canada and North America, where floating ice comes down. It is also safer in slow-running navigable streams.

There are many cases in which it is not necessary to drive piles, but the standards are instead stood on the river bed and enclosed with a mass of rubble [68], to prevent them from shifting. Or the two methods are used in combination, some standards being driven, others not, and the bases loaded with rubble and the upper portions braced. On land, standards are sometimes carried on horizontal timbers [71], as, of course, they must be also when a travelling staging is mounted on wheels [74].

Choice of Methods. What particular method shall be adopted in any case is a question for settlement by the engineer, who has to take all the local circumstances into consideration. The nature of the ground, the span, height, wind pressure, navigation, etc., all have to enter into the calculation, and a matter as important as any is that of cost.

Alternatives to Stagings. The staging method of erection of bridges is alternative to that of floating out bridge girders, or rolling them out from the shore, or building them out from their piers. It possesses the great advantages of giving the men a good platform to work upon, and under some conditions may thus prove less costly than other methods where no staging is used. The parts of the work that are being erected are not subjected to any strain, such as often occurs in the other methods, especially in the case of cantilever and girder bridges like that over the Forth, or the arched bridge just built over the Zambesi. Every member is supported by the staging until the last rivet is closed, and each is then subjected only to the normal stress for which it has been proportioned.

Joints. The methods of jointing the heavy timbers for staging admit largely of repetition—that is, the forms used are not very numerous, but they occur again and again. Some of the principal are shown.

It may be laid down as an axiom that the less

cutting done the better from the point of view both of economy and of strength; economy of time, and also in money, from the fact that the material is more saleable on the conclusion of a contract; strength, because deep cutting diminishes the strength of a section. Still, as *already remarked, it is seldom usual to trust to bolts alone for security, but joggling, even though shallow, is practised. Beams, stringers,* transoms, are notched or joggled, and struts are stub-tenoned. Strap bolts and through bolts figure largely as fastenings. Where these alone are not sufficient, straps *of forms suited to the joints and direction of joints of the beams are* laid against faces and bolted through. Numerous examples are grouped in 78—91. Fig. **78** illustrates the shouldering of an upright between two horizontals. Fig. **79** is similar, with the addition of a diagonal strut, which rests on a horizontal. Fig. **80** is a diagonal timber: a chock fills in the end, and the whole is bonded and bolted together. Fig. **81** is a diagonal strut abutting on a step or straining-piece, and secured by bolts. The long bolts flanking the diagonal go up to horizontal timber. Fig. **82** shows the detail of the other end of the diagonal fastening to the horizontal timber. Fig. **83** is another diagonal fastening made with long bolts. Fig. **84** is an intermediate tie securing a vertical to a diagonal member away from the end fastenings. Fig. **85** shows horizontals and verticals fastened with tenon and bolts, and a diagonal stub-tenoned; **86** is a right-angle fastening, tenoned and bonded with a strap bolted through; **87** shows uprights united to a horizontal with a joggled piece; **88** illustrates strutting attached with an iron knee; **89**, crossing diagonals shouldered into the upright; and **90** and **91** show various crossing joints shouldered and secured with covering straps and bolts. These do not exhaust the joints possible, but scarfed and joggled forms, and the methods of making mortises and tenons, etc., will be given in the course on CARPENTRY. The timber used for staging is usually deal or pitch pine.

Gantry Stagings. Gantries and staging for travelling cranes, crabs, erecting towers, and for fixed cranes, are used largely. The principles laid down are embodied in these. There are two principal types—the framed structure and the braced—and both kinds are made fixed or portable. Gantry framings of both kinds are shown with variations in the method of construction.

In the fixed type [**72** and **73**], which may be extended to any length, the work being an exact repetition of that shown, the cheapest style of construction is given. The various members are fastened with dogs. The verticals and horizontals are strutted, and diagonal struts afford stability at the ends [**72**] and sideways [**73**].

In the portable type [**74**], which has to be stable in itself, more care is taken with the joints and fastenings. On such end framings any superstructure can be raised, either timber beams for cranes or floorings. Strutting of these in a *direction at right angles with the plane of the framings must be done, and if the beams are of any considerable length they must be trussed.*

The travelling wheels must have their axles carried in cast-iron bearings bolted to the timbers, and in heavy gantries provision must be made for travelling by toothed gears operated by winch-handles.

Derrick Stagings. When it is necessary to hoist materials to a great height, as in the erection of tall buildings, a derrick crane mounted on a high staging [**71**] is more economical than a gantry with a travelling crane. The kind of stage employed for this purpose consists of three built-up legs, one at each corner of a triangular base. The main one, known as the king leg, supports the derrick. The other two are termed queen or chain legs, and their function is to afford anchorages for the guys of the derrick. These legs each consist of a square column of lattice-work formed by four vertical corner timbers, each of about 12 or 14 in. square, connected by horizontal and diagonal bracings. The king leg has a middle vertical timber, in addition to the corner ones, and is generally of larger dimensions than the queen legs, though all are of the same height. Owing to the great height, the vertical timbers have to be built up, either by fishing balks end to end, or by bolting a number of deals together and arranging them so that they break joint. A secure base of concrete or crossed balks must be prepared to erect this staging on. The legs are connected at the top by trussed girders, and below by diagonal timbers.

The legs are loaded with kentledge, either bricks, stones, or pig-iron. A chain is suspended from the extremities of the derrick legs, and is loaded near the ground. This prevents risk of overturning of the crane, or lifting of the back guys, which in ordinary cranes fixed to the ground is done by bolting them into the sleepers.

NATURE'S RECORDS OF EVOLUTION

The Story of Evolution Read in Rocks and Animals. Geological Succession of Animals. Theories of Weissmann, Beard, and Reid

By Dr. GERALD LEIGHTON

Geological Periods. The story of the rocks depends upon the fact that the deposits of sand, mud, limestone, and so forth, which are formed are arranged in successive layers, of *which those nearest the surface are the most* recent, unless some upheaval has occurred to alter the arrangement. Any given stratum or layer of rock, together with the fossil remains found in it, is therefore of greater antiquity than those which rest upon it, and of more recent date than those which are found underneath it.

From this fact geologists are able to arrange strata in their order of time, and thus to construct "the geological record." This record constitutes the story of the rocks. The details of it will be found in the course on Geology. We may simply note here that it can be divided into four great periods, which are characterised by fossils of corresponding types. These four periods are as follows:

1. THE KAINOZOIC EPOCH, the youngest of all, corresponding to the age of birds and mammals.
2. THE MESOZOIC EPOCH, corresponding to the age of reptiles.
3. THE PALÆOZOIC EPOCH, corresponding to the age of amphibians, fishes, and invertebrate creatures.
4. THE EOZOIC EPOCH, the age of unknown forms of life.

We ourselves live in the first of these epochs, the Kainozoic, a period which has lasted for a much shorter time than the Mesozoic, the latter in turn being shorter than the Palæozoic. It is quite possible that the Eozoic was longer than all three together. The entire record includes a thickness of stratified rocks of some 100,000 feet.

In order to illustrate the evidence afforded by a study of fossils in favour of organic evolution, we may take the case of one well-known mammal —the horse—and see what is known of the origin of this particular species.

The Evolution of the Horse. The horse may be regarded as one of the "show-pieces" of organic evolution, because a very long series of fossil horse-like creatures has been discovered which prove conclusively the course of events for this particular animal. They tell the gradual origin of the specialised modern horse from the primitive generalised ancestor. They show the relationship of the horse to other creatures, such as the tapir and the rhinoceros, which represent other stages of the horse evolution, a view which is borne out also by the facts of development.

The ancestors of the modern horse are represented in the geological deposits of both Europe and America, those of the New World being wonderfully complete. These remains are found in the tertiary rocks, the divisions of which are termed respectively *Pleistocene*, *Pliocene*, *Miocene* and *Eocene*, the last being the oldest and the first the newest of this series [see GEOLOGY]. The series is thus described by G. P. Mudge in his "Text-book of Zoology":

Fossil Horses. "The first fossil remains of the horse in America are found in the deposits of the *Upper Pliocene*, and they are in no way different from the corresponding portions in the recent horse, which is an animal whose limbs have become modified in accordance with the requirements of the rapidity of flight over undulating plains and a firm ground. Both the fore and hind limbs of the horse possess only one digit (third finger and toe respectively) and two splint bones, one on either side of the functional digit, which correspond in position to the bones of the middle hand or foot respectively.

"In the *Middle Pliocene*, the remains of an animal (*Pliohippus*) slightly smaller than the horse, and possessing its small hooflets, is found; farther down in the *Lower Pliocene*, an animal about as large as the ass, called *Protohippus*, is found, whose fore and hind limbs both possess three fingers and toes respectively, but only the middle one is functional and reaches the ground. Earlier still, in the *Upper Miocene*, *Miohippus*, of slightly larger stature than a sheep, is found, whose limbs possess three functionally developed digits and a small splint bone on the fore limbs; in the *Lower Miocene*, a smaller animal, *Mesohippus*, has the same three functional digits, but the splint bone is much larger. In the *Upper Eocene*, *Orohippus*, has four digits, or toes, of which only three reach the ground, the smaller one corresponding in position to the splint bone of *Mesohippus*. In the early *Eocene* *Eohippus*, with four functional digits and a remnant of a fifth, is found.

"As we search backwards through the record of the rocks, we can thus trace the successive stages by which the one-toed and one-fingered horse has been derived from a five-toed and five-fingered ancestor; and a comparison of the horse's limb with those of the animals mentioned above shows that the two splint bones correspond to the second and fourth digits, and the functional toe to the third one of the pentadactyl limb of the horse's ancestor."

How the Horse was Evolved. In the European rocks the record is not so complete, but is on precisely the same lines. The earliest form known has three functional toes—that is, three toes which reach the ground; a later form is found in which the two side digits are not functional, they do not reach the ground, but the middle one has become more prominent; and in a still later form this condition is accentuated. So that by the gradual disappearance of the outer fingers and toes, the present condition of the limb of the horse, that of having only one functional finger and toe, is reached.

It must not be imagined from these interesting discoveries that we have here a direct line of descent before us, or that one of these ancestral forms gave rise directly to the next known. The record is of necessity imperfect, and will doubtless receive many additions in future. Moreover, as we have seen, large groups of animals have disappeared without leaving us any trace hitherto discovered, the condition necessary for their preservation being absent.

We must not expect more than is reasonable from the nature of the case. Minute connecting links are doubtless lost for ever in the processes of decay. If we can find one variation here and there which points the way, it is as much as is to be expected. But the facts we have mentioned appear to admit of no other interpretation than that afforded by the theory of organic evolution, and the scientific imagination can readily picture the environments which accompanied the successive stages. The evidences of geology come to our assistance, and enable us to form some such picture of events as the following.

The Past Reconstructed. "The Eocene period, which was peopled among others by the tribe of the Eohippi, was a period of great geological unrest; great land masses were slowly sinking beneath the sea, and some of the great Alpine chain of mountains of the present day were being formed beneath the ocean, while others were in course of elevation above the sea-level. These elevations and subsidences were not sudden and cataclysmic, but occupied hundreds of thousands of years. There is evidence to show that the greater portion of Europe, and a large part of America, were at this period beneath the surface of the sea, or but little above it.

"The physical conditions of such a period must have been characterised by the presence of extensive marshy swamps, with here and there eminences of dry land. Under these swampy conditions of the ground, *Eohippus*, with its wide tetradactyl (*i.e.*, four digits) and the then but recently pentadactyl (*i.e.*, five digits) hand and foot, was favourably adapted, for it could move, if but slowly, at any rate with security.

Birth of a New Tribe. "In the latter part of the Eocene epoch the elevation of the ground was still proceeding, and much of it had become drier and firmer; during the same time there had appeared among the Eohippi stock certain individuals in which a spontaneous variation had appeared in the form of a less well-developed fourth toe (*Orohippus*). We know that a spontaneous variation of this kind is hereditarily transmitted, and that if both parents possess it the variation in the offspring is accentuated.

"Now, we may imagine, for there is nothing improbable or inconsistent with known facts in so doing, that such a favourable sexual union occurred, or, for the matter of that, that several did so. There would thus arise a progeny with strong innate and congenital tendency to a reduction of the fourth toe, and this progeny would interbreed and the variation become still more accentuated, until only a splint-bone (*metatarsal*) of the fourth toe was left. Thus would arise the tribe of Mesohippi.

"If we suppose that this variation in the direction of the loss of digits conferred any advantage upon the individual beyond that possessed by those in which such variation had not appeared, that, for instance, in the struggle for existence resulting from the tendency of animals to reproduce beyond the means of subsistence, a three-toed animal could move more quickly than a four-toed one, it would more easily obtain its food and have better chances of surviving and procreating its species than its less favourably adapted fellow.

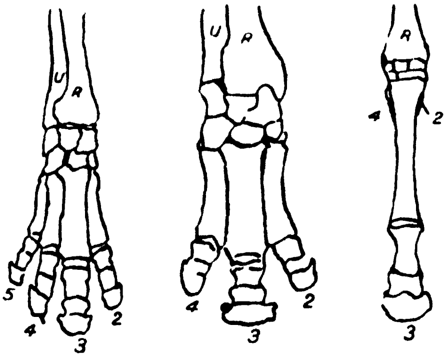
Variation to Suit New Conditions. "And this in reality must have happened; for, as the land gradually rose higher above the surface of the sea, the swampy areas favourable to the four-toed Eohippi would become more and more limited and the food supply therefore less, while the dry and firm areas would correspondingly increase and the food material which it could produce. And those forms which were best adapted to move over firm and dry ground would have more chances of surviving and reproducing their species than those which were only adapted for marshy swamps.

"In connection with this greater rapidity of motion, it must be remembered that the loss of toes was correlated with increase in the length of the limbs, in size of body, and alteration of the pattern of the teeth. All the swiftly moving ungulate animals of to-day are either single-toed, like the horse, or double-toed, like the deer; and for mechanical purposes the double-toed forms are really single-toed, for the two metacarpals of the fore limb and metatarsals of the hind limb are fused together in most instances." (Mudge.)

So, according to this view, the horse has been evolved from a primitive five-toed and five-fingered ancestor by the natural selection of spontaneous variations in the digits, variations which gave their possessors the advantage in the struggle for existence in their changing environment, particularly in the matter of obtaining food. This is the essence of the theory simultaneously announced by Darwin and Wallace, and the horse is one of the best examples of it which can be quoted.

Theory and Fact. Looking at the matter altogether apart from the theory of Darwinism, the actual specimens of these variations are found and can be seen. Successive forms showing all the differences mentioned between the five and one toed animal have existed, and no other reasonable explanation is forthcoming, except that these represent stages in the gradual evolution of the horse as we see it at the present time.

Additional Evidence. There is still another point which the case of the horse illustrates well. We know that modern species occasionally produce offspring which vary in the direction of their ancestors. They "throw back," in popular language; they exhibit "atavism," in technical terms. Does such a thing ever occur in horses? It does, in a most interesting manner. Horses have been met with which possessed toes corresponding to the form known as Hipparion, the two splint-bones having their corresponding digits. Still more commonly, we find the modern horse developing an extra tooth in front of the premolars, this tooth being known as the "wolf's tooth." Now, a normal modern horse does not possess this tooth, but it occurs constantly in one of the early European fossils, and as often as not in Hipparion. Such structures when they occur in modern individuals are termed "vestigial structures"; they represent structures which were once constant, but are now no longer existent, or are in actual course of disappearance. They form important additional evidences of the course of organic evolution. They cannot be accounted for upon any other supposition.



Tapir Rhinoceros Horse

VARIATIONS IN THE FORE FEET OF ANIMALS

U. Ulna R. Radius, 2, 3, 4, 5, respective digits

The Rhinoceros and Tapir. It is interesting to note that in some existing animals these variations of the limb are still to be seen. In the rhinoceros the second, third, and fourth digits on each foot are still retained. The reduction has not gone on to the stage of the horse. The rhinoceros remains three-toed. Professor Cossar Ewart has shown that in the unborn foal these second and fourth digits are represented by small projections on each side of the limb. Another variation is that seen in that most curious animal the tapir, a creature somewhat like a pig in general appearance but with a short proboscis. It dwells only in South America and the Malay region. Geological evidence shows that similar animals once existed in North America, Europe, and Asia, and this fact in itself is to be explained only by the theory of organic evolution, extinction having occurred in the intervening areas in the struggle for existence. The condition of the foot of the tapir, represented in the illustration (together with that of the horse and the rhinoceros), is that the fore limb possesses four digits, while the hind limb has only three. It is the comparative structure of the limbs, as represented by the presence or absence of digits, upon which we desire to lay special stress at this point. No other explanation but that afforded by the theory of organic evolution can explain the existence to-day of a creature having limbs made like those of the tapir.

The Geological Succession of Animals. We may here conveniently summarise the geological evidence of this matter, mentally resolving to learn more of this aspect of evolution from text-books especially devoted to the subject.

Fossil animal remains teach that the earlier the fossils the less are they like animals now on earth; the later the fossils the more nearly do they approximate to the species as now seen. The oldest fossils are those of the invertebrates, with a few fish. Many of these are generalised types as opposed to what we term specialised types. The more generalised types have disappeared in the struggle for existence, except in a few isolated cases, such as the tapir, one of the most generalised mammals existing. The succession of forms which point to the ancestry of the horse finds a parallel in the sea-urchins and ammonites, the older of which are more generalised, the latter having more special and elaborate structures. In the amphibians and reptiles those parts of the animals which are most used have undergone most elaborate specialisation from the ancient types, the specialisation being most marked in the more recent forms. In Palaeozoic times a large number of creatures existed which belonged to types which would now be quite useless in the present struggle for existence. They were extinguished, suddenly or gradually, by natural agencies, only the advantageous variations surviving. Nature has, throughout the ages which are gone, evolved by the agency of her own laws species of plants and animals best fitted for the changing environments. On the whole there has been progress, the best proof of which is the evolution of man himself.

We have now taken a general view of the problem of organic evolution, and examined the two great theories of the last century which attempted to account for the facts, with the result that we find ourselves more in accordance with the view advanced by Darwin and his followers than the older theory of Lamarck. But we at the same time freely admit that the last word concerning the origin of species was not said by Darwin, and that since he wrote a very great deal has been learnt which may very well modify the conclusions to which he came. Nevertheless, speaking broadly, all the evidence is on that side, and all the more recent views which have been advanced do not really contradict the essence of Darwinism, but rather strengthen its weak places. They all proceed from Darwin's foundation—*viz.*, the universal prevalence of variations of a spontaneous nature which can be transmitted by heredity, and which are in some way selected. Now, it is quite true that Darwin and Wallace used the term "Natural Selection" in a definite manner, in the sense in which we have used it in this course, and it follows that any other kind of selection is not, strictly speaking, Darwinian. What we wish to emphasise is that the later views are the lineal descendants of Darwinism, and bear upon their faces the imprint of their origin. They seek to answer some of the objections and difficulties which have been urged against natural selection as propounded by Darwin, to supply what many have thought was still required in order to account for all the facts. Of these quite recent views there are four which we must mention briefly in order to indicate the trend of thought at the actual moment of writing, and to prepare us for developments in the immediate future.

Weismann's Theory. Professor Weismann, of Freiburg, perceiving the difficulties of the natural selection theory, and having no faith at all in the other views, formulated a theory of selection which is termed "Germinal Selection." The essence of this law is that the struggle for nutrition—that is to say, the real struggle for existence—takes place in the germ-plasm itself before the development of the embryo. The germ is supposed to contain certain definite portions which give rise to corresponding parts of the developed body. If one of these germ-portions ("determinants," he terms them) is vanquished in the struggle for nourishment, it grows weaker than other parts which are better nourished, and gives rise to a minus variation —a negative variation—in the individual, who thus perishes because of the survival of those in whom this part is strong. Owing to the continuity of the germ-plasm, the process of weakening goes on with added force in successive generations, until at last that special portion of germ-plasm perishes, and the part which it represents therefore disappears from individuals.

We need only say here that this is pure theory, a mental conception to account for some observed facts. There is no actual evidence in existence to show that such things as "determinants" are in the germ-plasm. The theory is bound up with the theory of heredity put forward by Weismann, to which we shall refer later.

Dr. Beard's Theory. Dr. Beard also maintains a theory of "Germinal Selection." He believes that in sexual reproduction the whole number of characters of the two parents are mingled up to a certain point, just as the cards in two different packs might be mingled by shuffling them together. There will thus be in every fertilised germ-cell two representatives of each character or quality. At a certain stage after fertilisation one representative of each character or quality is eliminated or suppressed, the one to be preserved being that best suited to the environment of the germ-cell. According to Dr. Beard, selection occurs within the germ-cells, and there is a selection of germ-cells; he maintains, too, that this form of germinal selection is a much more potent factor in adapting species to the environment in which they find themselves than is the natural selection propounded by Darwin. "What it (*i.e.*, natural selection) would do, that, and far more than that, Nature brings about in a more efficient way by selecting in the germ-cell which of two characters or qualities, the greater or lesser, shall be taken." Dr. Beard believes that the environment of the germ-plasm is such that it selects portions of germ-plasm representing characters in a manner similar to, but more certain than, the way in which Darwin supposed individuals to be selected. Darwin would eliminate the unfit individuals in the struggle for existence. Dr. Beard would eliminate the unfit germ-cells. He attributes the variations to the action of the environment, to every part of which the germ-cells will react. Those which react favourably are selected, those which react unfavourably will diminish.

Dr. Archdall Reid's View. Archdall Reid, the well-known writer on evolution and heredity, also seeks to supply the unknown factor in organic evolution. He maintains that not only is there one great force at work in Nature—namely, Natural Selection—but that in addition there is another—namely, Reversion. "The former causes progressive evolution, the latter regressive evolution. They are opposed, but one would be quite inadequate without the other. They are warring forces, but their resultant is a near approach to perfection. Between them they tend to bring every species into exquisite harmony with its environment." "A variation may be progressive or regressive in type. A progressive variation constitutes a deviation from the parental *and* ancestral type, which, speaking generally, is in the direction of increased magnitude and complexity. It results from the complete recapitulation of the parental development *plus* an addition. A regressive variation constitutes a deviation from the parental *towards* the ancestral type. As a rule it is in the direction of diminished magnitude or complexity. It results from an incomplete recapitulation of the parental development. . . . Evolution is *adaptive* racial change. . . . The tendency to vary spontaneously has been evolved by Natural Selection. . . . Only inborn characters are transmissible to offspring. Evolution, therefore, proceeds solely on lines of inborn characters. Every individual in his development follows (with variations) in the footsteps of his predecessors. The development of every individual is, therefore, a recapitulation (with inaccuracies, with omissions and additions) of the life-history of his race. Since regressive variations tend to be of greater magnitude and prepotency than progressive variations, the tendency to regression is always greater than the tendency to progression. Consequently, progressive evolution can occur only when selection is somewhat stringent, and this is especially the case when a character has been recently and quickly evolved. It follows that, whenever the stringency of selection is relaxed, a character which has undergone evolution tends to regress. During the evolution of the species many parts become useless. Natural selection, therefore, has evolved bi-parental reproduction, which regulates the tendency to reversion in a very beautiful, effective, and discriminating manner. It aids natural selection to preserve structures and variations when they are useful, and assists regression to eliminate them when they are useless. . . . Natural selection seizing on progressive variations causes progressive evolution. Bi-parental reproduction seizing on regressive variations causes regressive evolution. The latter is a necessary accompaniment of the former. Natural selection, as commonly understood, therefore, explains only half the facts of evolution. The environment acting on, or through, the parent, has little or no effect on offspring subsequently born. . . . Evolution is due solely to natural selection. But besides the simple and direct elimination of the unfittest which Darwin describes, species are adapted to their environments by other means more subtle and exact." These brief extracts from Dr. Reid's book on "The Principles of Heredity" will serve to indicate his main contentions, and the work itself must be consulted for the arguments adduced in their support.

The Origin of Species by Mutations. We have left to the last the mention of a theory of organic evolution which, advanced only a year or two ago by De Vries, is rapidly assuming a very prominent place in the minds and beliefs of modern biologists. Like other modern views, it has a distinct flavour of Darwinism about it, but at the same time it has its own distinctive idea. It will be remembered that Darwin thought that plants and animals had evolved into species and varieties by a very slow and gradual process as a rule, this process depending upon the selection of somewhat *small and minute variations* which were accumulated by selection. Darwin's theory demands great periods of time for its accomplishment. He thought that very gradual change was the rule.

De Vries, on the other hand, has propounded the somewhat startling proposition that evolution in plants and animals is by no means so slow and gradual as was supposed, and that instead of species arising by the selection of small advantageous variations, they are often produced *suddenly* by large and very marked variations, which are transmitted to offspring and which breed true. According to this view the enormous periods of time demanded by the Darwinian theory are not required, and it accounts for the sudden appearance of species without any series of connecting links with others. These large variations, which De Vries believes give rise to new species, he terms "mutations," to distinguish them from the smaller modifications or "variations" of the older view. Of all the views put forward since Darwin's, this is the most far-reaching. It threatens a revolution in biological thought almost as great as that which followed the enunciation of Darwinism.

Evidences for the Mutation Theory. De Vries has proved experimentally that these large variations frequently occur, and, more than that, he has proved that they breed true to themselves. In other words, he has shown that their origin is in the germ-plasm and not in the body, or soma. His theory does not involve a belief in the transmission of acquirements, since he deals with germinal, not somatic, variations. Like Darwin, he depends upon natural selection for the mode of operation. Darwin based his theory largely on the practice of breeders in selecting artificially. De Vries shows that this artificial selection depends largely, if not entirely, on the selection of these *large* variations, or "mutations," and his view is confirmed by experiments made in this country by Hurst, who has used rabbits and plants for this purpose. The opinion is gradually gaining ground that organic evolution is in the main due to these mutations rather than to small variations.

It is only right to add that Bateson, of Cambridge, was the first to point out the importance of these "discontinuous variations" which De Vries terms "mutations." The existence of them was noted by Darwin, but he regarded them as of comparatively little importance, as those known to him were chiefly monstrosities. Since that time we have learnt a great deal more about their nature and frequency of occurrence.

It is never safe to prophesy, but we venture to think that in the future the origin of new species by mutations will be recognised as a most important, if not *the* most important, method of organic evolution.

SECTION I. GRAMMAR

Irregular Verbs : Second Conjugation

The most important exceptions to the regular formation of *-ui* and *-itum* are :

Perfect *-vi*, Supine *-tum*

deleo	delēre	delevi	deletum	*blot out*

(So also *Fleo* = weep, and *-pleo* = fill.)

Perfect *-ui*, Supine *-tum*.

doceo	docēre	docui	doctum	*teach*
misceo	miscēre	miscui	mistum	*mix*
teneo	tenēre	tenui	tentum	*hold*

Perfect *-si*, Supine *-tum*.

augeo	augēre	auxi	auctum	*increase*
torqueo	torquēre	torsi	tortum	*twist*
lugeo	lugēre	luxi	—	*mourn*

Perfect *-si*, Supine *-sum*.

mulceo	mulcēre	mulsi	mulsum	*soothe*

Similarly, *ardeo* (take fire), *rideo* (laugh), *suadeo* (advise), *maneo* (remain), *jubeo* (order, perf. jussi), *hæreo* (stick), *fulgeo* (glitter).

Perfect *reduplicates*, Supine *-sum*.

mordeo	-ēre	momordi	morsum	*bite*
pendeo	-ēre	pependi	pensum	*hang*
spondeo	-ēre	spopondi	sponsum	*pledge*
tondeo	-ēre	totondi	tonsum	*shear*

Perfect *-i*, Supine *-sum*.

prandeo,	-ēre	prandi	pransum	*dine*
sedeo,	-ēre	sedi	sessum	*sit*
video,	-ēre	vidi	visum	*see*

Perfect *-i*, Supine *-tum*.

caveo,	-ēre	cavi	cautum	*beware*
faveo,	-ēre	favi	fautum	*favour*
foveo,	-ēre	fovi	fotum	*cherish*
moveo,	-ēre	movi	motum	*move*
voveo,	-ēre	vovi	votum	*vow*

[Notice that most of our English nouns are derived from Supines—*e.g.*, torture, tonsure, vision, session, etc.]

Also three deponents :

fateor	fatēri	fassus	*confess*
misereor	miserēri	misertus *or* miseritus	*have pity on*
reor	rēri	ratus	*think*

The Roman Calendar

Names of the Roman months (all adjectives) :

Januarius, a, um
Februarius, a, um
Martius, a, um
Aprilis, e
Maius, a, um
Junius, a, um
Quintilis, e (*or* Julius)
Sextilis, e (*or* Augustus)
September, bris, bre
October, bris, bre
November, bris, bre
December, bris, bre

[The year originally began with March ; therefore, July was the fifth, September the seventh month, and so on. *Quintilis* and *Sextilis* were later called *Julius* and *Augustus* in honour of Julius Cæsar and the Emperor Augustus.]

Every Roman month had three chief days : *Kalendæ, -arum* (Calends) ; *Nonæ, -arum* (*Nones*), *Idūs, Iduum* (Ides) : all three feminine. The Calends were always on the 1st ; the Nones usually on the 5th, and the Ides usually on the 13th. But in March, May, July, and October, the Nones and Ides were two days later—*i.e.*, on the 7th and 15th respectively.

From these days the Romans counted *backwards*, the days between the 1st and the Nones being reckoned as so many days before the Nones ; the days between Nones and Ides, as so many days before the Ides ; and the remaining days of the month as so many days before the Calends of the next month.

1. When the date falls on one of the three chief days, the date is put in the abl., the month, of course, agreeing with the noun

Jan. 1st *Kalendis Januariis.*
March 15th. *Idibus Martiis.*
Nov. 5th. *Nonis Novembribus.*

2. The day immediately preceding any of these three reckoning points was called "pridie" (*i.e.*, priore die), followed by the acc.

Jan. 31st. *Pridie Kalendas Februarias.*
Apl. 12th. *Pridie Idus Apriles.*
Oct. 6th. *Pridie Nonas Octobres.*

3. In any other date, we find out how many days it is before the next Calends, Nones, or Ides, (remembering to count in both the date in question *and* the Calends, etc.). Thus, Jan. 30th is the *third* day before the Februarian Calends, and would be in Latin *ante diem tertium Kalendas Februarias.*

Further examples :

Dec. 2nd. *Ante diem quartum Nonas Decembres.*

March 16th. *a.d. septimum decimum kalendas Apriles.*

These are usually written "a.d. IV. Non. Dec.," and "a.d. XVII. Kal. Ap.," and so with the others. The original signification of this expression seems to have been "before (on the fourth day) the Nones of December," the exact day being thrown in parenthetically, and attracted from abl. to acc. in consequence of following "ante."

4. In Leap Year, Feb. 24th (a.d. VI. Kal. Mart.) was reckoned twice, hence this day was called *dies bissextus*, and leap year itself, *annus bissextilis*.

SECTION II. COMPOSITION.

The Subjunctive Mood. This is one of the most difficult subjects in Latin. English usage gives no guidance, and, in fact, the subj. is as common in Latin as it is rare in English. In the following sentences, for example, the words in italics would be in the subj. mood in Latin: "It was so cold that the water *froze*" (consecutive after *ut*). "I asked why he *did* this?" (indirect question). "I fear that you *are* ill." "He said that the man who *did* this should die" (dependent verb in Oratio Obliqua). "There is no doubt that twice two *are* four." Roughly, we may say that the indicative indicates a fact, while the subj. expresses "something which we regard rather as a mere conception of the mind, as that which we purpose or wish to be a fact, or to which we refer as the result of another fact, or as stated on other authority than our own."

Usually, the subjunctive is used in certain classes of subordinate or *subjoined* clauses. But it is also used both in simple sentences and in the main clause of a compound sentence in the following cases:

1. To make a statement in a hesitating manner, sometimes called the potential mood. This is strictly a hypothetical subj. with the condition not formally expressed.

Hoc dicere ausim = I would dare to say this (if I were allowed).

Vix crediderim = I can hardly believe.

Hoc facias velim I would have you do this ("ut" understood with "facias").

2. To ask a question, rhetorically, not for information; sometimes called dubitative questions. Usually a negative answer is expected.

Quis credat? = who would believe?

Quid ego facerem = what was I to do?

3. To express a wish or desire (optative or jussive), often with *utinam* (= would that!). Negative *ne*.

Utinam adjuvisset = would he had been present!

Di Carthaginem deleant = may the gods destroy Carthage.

Ne transieris Iberum = do not cross the Ebro. (In negative commands, use the perf. subj., not the imperative. Or else say *noli transire* = be unwilling to cross.)

Only in these classes of sentences is the subj. found in simple or principal sentences. In all the rest it is in subordinate sentences. Including those given above, there are eight main uses of the subj. mood:

1. Hypothetical: see No. 1 above. In these sentences the protasis (*i.e.*, the *if* clause of a conditional sentence) is suppressed.

2. Conditional—*e.g.*, *Si jussisses* (protasis), *fecissem* (apodosis) = if you had bidden, I should have done it. *Si adsis, facturus sum* = if you should be there, I mean to do it.

3. Optative, jussive, or concessive (see No. 3 above). "The imperative is the language of an absolute master: the subj. is a suggestion to an equal or superior."

• In concessive sentences, a person rhetorically commands or supposes a change of what he knows or believes to be the fact.

4. Final, expressing purpose (negative *ne*).

(*a*) In adjectival sentences: *Dignus est qui vincat* = he is worthy to conquer. *Mitto qui dicat* = I send someone to say.

(*b*) In sentences introduced by *ut* (in order that), *ne*, *quo*, *quominus*, *quin*: *Ede ut vivas* = eat that you may live. *Non vixit ut ederet* he did not live to eat.

(*c*) In sentences of time or condition, with *dum*, *dummodo*, *donec*, *priusquam*, etc. *Oderint dum metuant* = let them hate provided they fear.

5. Consecutive, expressing result; usually with *ut* so that (negative, *ut non*): *Tam debilis sum ut non ambulare possim* I am so feeble that I cannot walk. *Is sum qui illud faciam* = I am the man to do that.

6. Subj. of attendant circumstances: *Quæ quum ita sint, hoc dico* under these circumstances (lit. since which things are so), I say this. *Peccavisse videor qui illud fecerim* I seem to have sinned inasmuch as I have done that.

7. Subj. of reported statements, comprising sentences of definitions, reasons, and questions, which are given *not as the speaker's own*, but as someone else's.

Contrast "Laudat puerum quod *fuit* abstinens" (the reason alleged being given on the speaker's own authority) with "Laudat puerum quod *fuerit* abstinens" (the reason being a reported or assumed one, "He praises the boy, because he understands the boy to be abstemious").

8. Subj. because dependent on another subj. or infinitive. In all such sentences the subjunctive simply prevents the speaker from being supposed to be responsible for the statements, etc., reported, or to be giving them as independent assertions. To this head, of course, belongs the subj. in Oratio Obliqua. Examples:

(*a*) Depending on infinitive:

Dicit eos qui boni essent beatos esse (he says that those who are good are happy).

(*b*) Depending on another subjunctive:

Petit ut iis qui adfuerint credamus (he asks that we should believe those who were present). In such a case as this it is often said that *adfuerint* is *attracted* into the subj. by *credamus*.

TO BE TURNED INTO LATIN PROSE.

THE FUNERAL OF OLIVER CROMWELL.

BY ABRAHAM COWLEY.

It was the funeral-day of the late man who made himself to be called Protector. And though I bore but little affection, either to the memory of him, or to the trouble and folly of all public pageantry, yet I was forced by the importunity of my company to go along with them, and be a spectator of that solemnity, the expectation of which had been so great that it was said to have brought some very curious persons and no doubt singular virtuosos) as far as from the mount in Cornwall and from the Orcades. I found there had been much more cost bestowed, than either the dead man, or indeed death itself, would deserve. There was a mighty train of black assistants, among which, too, divers princes in the persons of their ambassadors (being nfinitely afflicted for the loss of their brother) were pleased to attend ; the hearse was magnificent, the idol crowned, and (not to mention all other ceremonies which are practised at royal nterments, and therefore by no means could be omitted here) the vast multitude of spectators made up, as it uses to do, no small part of the spectacle itself.

LATIN VERSION OF THE ABOVE.

Dies erat quo inferebantur tumulo reliquiæ illius qui Protectoris nomen occupaverat. Me,[5] quamvis[6] neque[7] viri[11] memoriæ[10] neque[12] operosæ[13] publicarum[15] sollemnitatum[16] vanitatis[14] admodum[8] studiosum[9], perpulere[4] tamen[3] sociorum[2] preces[1] ut cum iis spectarem pompam illam, quæ tam cupide jamdudum fuerat expectata, ut nonnulli curiosiores, limatissimo nimirum ingenio homines, usque a monte apud Cornubios et ab Orcadibus insulis *visendi causâ** in urbem progressi essent. Intellexi multo plus in funus erogatum esse quam pro mortui meritis, immo pro mortis ipsius dignitate. Ingens pulatorum ordo, assistentibus etiam quibusdam legatis, qui regum personas fratrem summo studio desiderantium sustinerent : feretrum splendidissimum ; coronata effigies ; denique, ne omnia alia commemorem quæ, utpote in regum funeribus sollemnia, hic nullo modo omitti poterant, pars haud exigua spectaculi fuit, ut fit, vasta spectantium multitudo. (J. Conington.)

SECTION III. TRANSLATION.

A LETTER FROM CICERO TO HIS FRIEND ATTICUS. WRITTEN IN MARCH, B.C. 46 :

Undecimo die postquam a te discesseram, hoc litterularum exaravi egrediens e villa ante lucem, atque eo die cogitabam in Anagnino, postero autem in Tusculano ; ibi unum diem. V. Kalend. igitur ad constitutum ; atque utinam continuo ad complexum meæ Tulliæ, ad oscuum Atticæ possim currere ! quod quidem ipsum scribe, quæso, ad me, ut, dum consisto in Tusculano, sciam quid garriat, sin rusticatur, quid scribat ad te, eique interea aut scribes salutem aut nuntiabis, itemque Piliæ. Et tamen, etsi continuo congressuri sumus, scribes ad me, si quid habebis.

Cum complicarem hanc epistolam, noctuabundus ad me venit cum epistola tua tabellarius, qua lecta de Atticæ febricula scilicet valde dolui. Reliqua, quæ exspectabam, ex tuis litteris cognovi omnia ; sed quod scribis " igniculum matutinum gerontikon " (a Greek adjective, meaning " characteristic of an old man "), gerontikoteron (comparative) est memoriola vacillare : ego enim IV. Kal. Axio dederam, tibi III., Quinto, quo die venissem, id est prid. Kal. Hoc igitur habebis, novi nihil. Quid ergo opus erat epistola ? Quid ? cum coram sumus et garrimus quicquid in buccam ? Est profecto quiddam " lesche " (gossip), quæ habet, etiam si nihil subest, collocutione ipsa suavitatem.

ENGLISH VERSION OF ABOVE.

Eleven days after leaving you, I am scrawling this bit of a note as I am starting from my country-house before dawn. I think of being at my villa at Anagnia to-day, and Tusculum to-morrow. Only one day there, so I shall turn up to time on the 28th, and, oh that I could run on at once to embrace my Tullia and give Attica a kiss ! As to this very thing, do write me, I beg you, that while I am stopping at Tusculum I may know what she is prattling, or, if she is in the country, what she writes to you about. Meanwhile, either send or give her my love, and also to Pilia. Yet even though we shall meet immediately, write to me if you have anything to say.

P.S. When I was fastening up this letter, your courier reached me after travelling all night with your letter. I am very sorry, you may be sure, to hear, on reading it, about Attica's fever. All the other news I was waiting for I now know from your letter, but when you write that " to want a little fire in the morning is a sign of old age," I retort " it is a surer sign of old age that one's poor memory should falter." For I had intended to spend the 29th with Axius, the 30th with you, and the 31st with Quintus. So take that for yourself : you shall get no news. Then why write, you say ? And, pray, what is the use of our chattering when we are together and saying whatever comes to our tongues ? Surely there is something in a good gossip after all : for even if there is nothing in it, the very act of our talking together has a charm of its own.

---

* *Causâ* is an abl. -- for the sake (or purpose) of ; it follows the word which it governs. Here translate " for the purpose of seeing."

ADVERBS

Just as adjectives qualify nouns, so adverbs modify or limit verbs—as, " Agag came unto him *delicately*." " He gives *twice* who gives *quickly*." This usage has been extended, and adverbs can now modify adjectives and other adverbs in addition to verbs, as: " Too many cooks spoil the broth " (*too* modifying the adjective *many*). " He struck me *very* forcibly " (one adverb *very* modifying another, *forcibly*).

Adverbs, like adjectives (from which they are mostly formed), are usually classified according to their meaning: just as we divided adjectives into Qualitative, Quantitative, and Relational, so we can divide adverbs. Thus:

1. ADVERBS OF QUALITY: *Well, ill, badly,* and all the adverbs in *-ly* derived from adjectives: *how, however, so, as, likewise,* etc. (sometimes called Adverbs of Manner).

2. ADVERBS OF QUANTITY:

a. Degree: *Very, nearly, almost, too, quite, enough, rather, much, more, most, little, less, least, only, but, just, even, any, the* (as in "*the* more *the* merrier"). Also the adverbs of Affirmation and Negation: *Not, no, nay, aye, yea, yes.*

b. Repetition of Time—as, *once, twice, thrice, often, seldom, always,* etc.

3. ADVERBS OF RELATION, showing

a. Time: *Now, then, after, before, soon, ago, instantly,* etc.

b. Place and Arrangement: *Firstly, secondly, thirdly, here, there, hither, thither, hence, thence, inside, outside, up, down,* etc.

c. Cause and Consequence: *Why, therefore, wherefore, accordingly, consequently,* etc.

It will be noticed that some of the words appearing in this list of adverbs have previously appeared as other parts of speech. *As,* for example, was included under Relative Pronouns; and *much, little, no, any,* were included under adjectives. To determine what part of speech a word is in a given sentence, we must consider the purpose it serves. Thus, "This is the same *as* that" (relative pronoun = "This is the same which that is"); "*As* he went out, he wept bitterly" (adverb denoting the time of the action). Again, "Give him *no* peace" (adjective), "This is *no* better than that" (adverb). Similarly, *much, little,* and *any* before comparatives are adverbs.

Formation of Adverbs. 1. From Adjectives. Most adverbs are formed by adding *-ly* to the corresponding adjective—*e.g., wild, wildly; cheerful, cheerfully.* The termination *-ly* (= like), is the Anglo-Saxon termination *-lic* (adjective), *lice* (adverb).

Adjectives ending in *y* preceded by a consonant change *y* into *i* before *ly*—*e.g., hearty, heartily; speedy, speedily. Shy* is an exception, making *shyly,* not *shily.* The adjective *gay,* which should strictly have *gayly* as its adverb, now usually makes *gaily.*

Adjectives ending in *-le* change the *e* into *y*—*e.g., noble, nobly; horrible, horribly.* When the adjective already ends in *-ly* the same form is generally used for the adverb—*e.g.,* the adverb of *godly* is usually *godly* ("We should live soberly, righteously and *godly* in this present world," Titus ii. 12), though *godlily* is sometimes used nowadays. So also *likely*: "a likely story" (adjective); "he will very *likely* come (adverb). Other adverbs derived from adjectives are *once, twice, thrice* (for *ones, twyes, thries*), *unawares, flatlong.* Some adjectives, in addition to those ending in *-ly,* are used as adverbs without any change of form—*e.g.,* "run *fast,*" "stand *firm,*" "strike *deep,*" "*pretty* good," "Think not so *slight* of glory" (Milton).

2. From Nouns. *Needs* (as in "If I must needs glory"), *whiles, sideways, lengthways, straightways, noways,* are genitive cases of nouns. *Whilom* ("at whiles," "formerly") and *seldom* are dative cases plural of *hwil* (= space of time), and *seld* (= rare). Other adverbs derived from nouns are *headlong, sidelong, piecemeal* (mael = part), *inchmeal* ("All the infections that the sun sucks up . . . on Prosper fall, and make him by *inch-meal* a disease!"—*Tempest*), *limb-meal* ("O that I had her here to tear her *limb-meal*"—*Cymbeline*), *sometimes, always, perhaps, otherwise, midway,* etc. Many adverbs are compounds of the preposition *a* (meaning *on*) and a noun, as *afoot, abreast, aside, asleep;* while some are compounds of other prepositions with nouns, as *betimes* (by times), *besides, indeed.*

3. From Pronouns. *Thus, then, than; here, hither, hence; there, thither, thence; where, whither, whence; why, how* (for *whow*), and all the other adverbs formed from the Relative Pronouns, such as *wherefore, whereat, wherein, whereby,* etc.

These adverbs, that are derived from the Relative Pronouns (with the addition of *as* and *in*), are *Connective* or *Conjunctive* adverbs; that is, they retain the connective power which we have seen belong to Relative Pronouns. A Connective adverb introduces a subordinate clause, and modifies the predicate of this clause. There is always an antecedent expressed or understood in the principal sentence: thus, "He fell full length, *whereat* the bystanders laughed immoderately" (*whereat* modifies *laughed;* we know it to be a Connective or Relative adverb because we could substitute "and thereat" for it). Again, "And now, too soon for us, the circling hours This dreaded time have compassed, *wherein* we Must bide the stroke of that long-threatened wound" (*Paradise Regained*).

Here we could substitute "and therein" for "wherein." The antecedent here is *time;* in the previous illustration the antecedent is "the fact of his falling." These Connective Adverbs must be distinguished from Conjunctions.

Negative Adverbs. *Not* is shortened from *nought* or *naught,* and literally means "in no whit, in no degree." In Old English, *ne* (= *not*) is employed before the verb, and a form corresponding to *naught* after the verb, the two negatives strengthening each other; thus, in Robert of Gloucester's *Chronicle* (A.D. 1298) we find "*Ne* be thou naught so sturne" ("Be thou not in any way so stern"), and in Chaucer's *Canterbury Tales* we have

"There was also a Doctour of Physik,
In all the world *ne* was there *none* him like.'

Also "Nor hath not one spirit to command" (*Tempest*).

In modern English, two negatives, so far from strengthening each other, neutralise each other.

although Matthew Arnold follows the old usage when he writes:

> "No easier nor no quicker pass'd
> The impracticable hours."

No and *nay* are from *na*, meaning *never*, while *aye* (affirmative) is from *a*, meaning *ever* (cf. *for aye*, meaning *for ever*. "This world is not for aye," *Hamlet*). *Yes* is from Anglo-Saxon *gese* or *gea*, yea, and *sy* (subjunctive mood, meaning "let it be").

Comparison of Adverbs. Most adverbs are compared by prefixing *more* and *most* to the positive, as *willingly, more willingly, most willingly*. But a few, and especially those which have the same form as the corresponding adjectives, are formed by the suffixes *-er*, *-est*; as:

Positive.	*Comparative.*	*Superlative.*
firm	firmer	firmest
fast	faster	fastest
soon	sooner	soonest
early	earlier	earliest

The following are irregular (see "Comparison of Adjectives" on page 446):

Positive.	*Comparative.*	*Superlative.*
well	better	best
badly, evilly, *or* ill	worse	worst
much	more	most
far	farther	farthest
forth	further	furthest
nigh *or* near	nearer	nearest next
late	later latter	latest last
[rathe, *adjective*]	rather	—
—	ere	erst
lief	liefer	—

Rathe meant *quick, early*; *Rather*, therefore, means *quicker, earlier, sooner*. Thus, in *Piers the Plowman*, by William Langland (A.D. 1362), we find it used as an adverb:

> "Let not thi luft hond, late ne *rathe*,
> Beo war what thi right hond worcheth or deleth."

("Let not thy left hand, late nor early, be aware of what thy right hand worketh or distributeth.")

Also Milton in *Lycidas* has "the *rathe* primrose" (adjective). Rath is still used in the Sussex dialect, as "Happens you were up *rath* this morning" (adverb), "She is given to taking long rambles in the *rath* morning" (adjective).

Ere is the Anglo-Saxon *aer*, a comparative adverb of time. It is now used mainly as a conjunction. *Erst* means *formerly*, and is shortened from *aerest*.

Position of Adverbs. Adverbs are usually placed as near as possible to the words they modify, and generally *before* an adjective or other adverb, and *after* a verb. For emphasis, however, an adverb may precede the verb, and even stand as the first word of a sentence. The poets take liberties with adverbs, and place them as they like; thus, Milton writes: "The rest . . . . will far be found unworthy to compare with Sion's songs," instead of "far unworthy." This usage should not be imitated.

FRENCH

Continued from page 1064

By Louis A. Barbé, B.A.

THE VERB

First Conjugation

The first conjugation consists of verbs of which the infinitive ends in *er*: *aimer*, to love, like; *donner*, to give; *garder*, to keep; *marcher*, to walk; *regarder*, to look: *représenter*, to represent.

The endings of all regular verbs of the first conjugation in the present indicative are: *e*, *es*, *e*, *ons*, *ez*, *ent*.

Affirmatively.

j'aime, I love
tu aimes, thou lovest
il aime, he loves
elle aime, she loves
nous aimons, we love
vous aimez, you love
ils aiment, they (m.) love
elles aiment, they (f.) love

Negatively.

je ne donne pas, I do not give
tu ne donnes pas, thou dost not give
il ne donne pas, he does not give
elle ne donne pas, she does not give
nous ne donnons pas, we do not give
vous ne donnez pas you do not give
ils ne donnent pas, they (m.) do not give
elles ne donnent pas, they (f.) do not give

The syllable *ent* of the third person plural is mute.

EXERCISE VI.

Vocabulary.

un appétit, an appetite
un arbre, a tree
une aubépine, a hawthorn
un aubour, a laburnum
en automne, in autumn
la baie, the berry
le bâtiment, the building
le bord, the edge
le bout, the end
la brebis, the sheep
la campagne, the country
la cerise, the cherry
le cerisier, the cherry tree
la charrette the cart
le chaume, the thatch
le cheval, the horse
le clocher, the steeple.
la colline, the hill
le contrevent, the shutter
la cour, the courtyard
la couverture, the cover
le cuisinier the cook
une eau, a water
une écurie, a stable (for cattle)
une église, a church
en été, in summer
une étable, a stable (for horses)

un exercice	**an exercise**
la faim	the hunger
la ferme	the farm
le festin	the feast
la feuille	the leaf
la fille	the girl
le fruit	the fruit
le facteur	the postman
la girouette	the vane
la gravure	the engraving
l'herbe (f.)	the grass
en hiver	in winter
un homme	a man
le houx	the holly
le jardin	the garden
la jument	the mare
la laine	the wool
le lait	the milk
le laurier	the laurel-tree
la lettre	the letter
le lilas	the lilac
le magasin	the shop
le mets	the dish (food)
la neige	the snow
le pré	the meadow
la personne	the person
la poire	the pear
le poirier	the pear-tree
la pomme	the apple
le pommier	the apple-tree
le pont	the bridge
au printemps	in spring
le repas	the meal
la rue	the street
le réverbère	the street-lamp
la rivière	the river
le sac	the bag
le sorbier	the mountain-ash
la terre	the ground
le trottoir	the footpath
la vache	the cow
le verger	the orchard
la ville	the town
une yeuse	an evergreen oak
la voiture	the carriage
agréable	pleasant
beau	fine, beautiful
blanc	white
bon	good
clair	clear
doux	sweet
frais	fresh
fin	delicate, dainty
grand	big, tall
gai	cheery
haut	high
joli	pretty
large	broad
luisant	glossy
mûr	ripe
nouveau	new
nu	bare
piquant	prickly
plein	full
propre	clean
rouge	red
savoureux	luscious
triste	dreary, sad
utile	useful
vert	green
vieux	old
garder	to keep
je prends	I take
je vais	I go
je vois	I see
à	at, to
au delà de	beyond
de	of, from
derrière	behind
devant	before, in front of
par	through, by
parmi	amongst
aussi	also
plusieurs	several
toujours	always
quand	when

I look through the window. In front of the window there is a large garden. In the garden there are some trees. Amongst the trees there are a fine laburnum, a pretty lilac, a hawthorn, an evergreen oak, and a mountain-ash. There are also some laurel-trees. They are always green. The evergreen-oak also is always green. In autumn the mountain-ash has berries. They are red. In winter the holly has berries also. The leaves of the holly are glossy and prickly. In spring the holly and the mountain-ash have no berries. Beyond the trees I see a bridge. Under the bridge there is a small river. The water of the river is fresh and clear. Beyond the bridge there is a broad street. The street has two footpaths. At the edge of the footpaths there are some street-lamps. In the street there are several persons. They walk on the footpath. One of the persons is a postman. He has a bag full of letters. There are also a carriage and a horse. There is no cart. At the end of the street there is a church. It has a fine steeple. The steeple is high. It has a vane. The church is not old, it is new. From the window I go to the table. I take a little book. The cover of the book is blue. In the book there are some pretty engravings. One of the engravings represents a farm. The farm is in a large courtyard. It has a stable-for-horses and a stable-for-cattle. In the stable-for-cattle there are cows. The cow gives milk. The stable is the horses' house. The stable is not a large building. In the stable there are a young horse and an old mare. Near the farm there is a meadow. In the meadow there are sheep. A little girl keeps the sheep. The sheep gives wool. The wool of the sheep is useful to (the) man. Behind the farm there is an orchard. In the orchard there are apple-trees, pear-trees, and cherry-trees. (The) apples are the fruit of the apple-tree. (The) apples are good when they are ripe. (The) cherries are the fruit of the cherry-tree. They are sweet. (The) pears are luscious. I like the country. In summer I go to the country. I have a little house on a pleasant hill. It is white. The shutters are green. The roof is of thatch. It is clean and cheery. In (at) the country (the) exercise gives a new appetite. (The) hunger is a good cook (f.). The dishes are dainty. The meals are feasts. In winter I do not like the country. It is bare and dreary. The trees have no leaves. There is snow on the ground. In winter I like the town.

FORMATION OF THE PLURAL

Nouns and Adjectives

Nouns and adjectives form their plural in the same way, and according to the following rules:

1. To form the plural of nouns and adjectives, add *s* to the singular: *le livre*, the book, *les livres*, the books; *un enfant poli*, a polite child, *des enfants polis*, polite children; *la belle orange*, the fine orange, *les belles oranges*, the fine oranges.

2. When the singular ends in *s*, *x*, *z*, there is no change for the plural: *le fils*, the son, *les fils*; *la voix*, the voice, *les voix*; *le nez*, the nose, *les nez*; *un fils doux et soumis*, a gentle and dutiful son, *des fils doux et soumis*.

3. When the singular ends in *au*, *eau*, *eu*, the plural is formed by adding *x*: *le noyau*, stone (of fruit), *les noyaux*; *le bateau*, boat, *les bateaux*; *le feu*, fire, *les feux*; *un livre hébreu*, a Hebrew book, *des livres hébreux*. The noun *landau*, landau, and the adjectives *bleu*, blue, and *feu*, late (deceased), take *s* for the plural: *un landau bleu*, a blue landau, *des landaus bleus*; *le feu prince*, the late prince, *les feus princes*.

4. The following seven nouns in *ou* also take *x* for the plural: *bijou*, jewel; *caillou*, pebble; *chou*, cabbage; *genou*, knee; *hibou*, owl; *joujou*, toy; *pou*, louse. All other nouns in *ou*, and all adjectives in *ou* take *s*: *le clou*, nail, *les clous*; *le verrou*, bolt, *les verrous*; *un corps mou*, a soft body, *des corps mous*; *un prix fou*, an extravagant price, *des prix fous*.

5. When the singular ends in *al*, the plural is formed by changing *al* into *aux*: *le mal*, evil, ache, *les maux*; *le cheval*, horse, *les chevaux*;

le tribunal, *les tribunaux*; *un conseil amical*, friendly advice, *des conseils amicaux*; *l'instinct brutal*, brutal instinct, *les instincts brutaux*. Exceptions: The following (*a*) nouns and (*b*) adjectives take *s* for the plural: (*a*) *aval*, endorsement; *bal*, ball (party); *cal*, callosity; *carnaval*, carnival; *chacal*, jackal; *nopal*, nopal (Indian fig); *pal*, pale; *régal*, treat; (*b*) *fatal*, *final*, *filial*, *glacial*, *jovial*, *magistral* (masterly), *matinal* (matutinal), *mental*, *natal*, *naval*, *pénal*, *sentimental*.

6. The nouns in *ail* in common use are nearly equally divided between (*a*) those that form their plural by changing *ail* into *aux*, and (*b*) those that only add *s*.

(*a*) *Bail*, lease, *baux*; *corail*, coral, *coraux*; *émail*, enamel, *émaux*; *soupirail*, air-hole, *soupiraux*; *vantail*, leaf of folding-door, *vantaux*; *vitrail*, stained-glass window, *vitraux*.

(*b*) *Camail*, bishop's cape, *camails*; *détail*, detail, *détails*; *éventail*, fan, *éventails*; *gouvernail*, rudder, *gouvernails*; *poitrail*, chest (of horses), *poitrails*; *portail*, porch, *portails*.

7. The plural of some nouns offers peculiarities and irregularities: (*a*) *aïeul* in the singular means grandfather, and has *aïeuls* for its plural: *il a deux aïeuls*, he has two grandfathers. It has a second plural form with the meaning of ancestors: *il a des aïeux nobles*, he has noble ancestors. In this second sense the word is never used in the singular. It is customary to say "one of the ancestors," instead of "an ancestor."

(*b*) *Ail*, garlic, has two plurals, *ails* and *aulx*. Botanists prefer the regular form: *la famille des ails*, the garlic family. The irregular form is more commonly used: *il y a des aulx cultivés et des aulx sauvages*, there are cultivated garlic plants and wild garlic plants.

(*c*) *Ciel*, sky, heavens, usually has the plural *cieux*: *la voûte des cieux*, the heavenly vault. When *ciel* is used (*a*) to indicate the skies of pictures, (*b*) as the equivalent of climate, or (*c*) in a figurative sense, its plural is *ciels*: (*a*) *il peint de beaux ciels*, he paints beautiful skies; (*b*) *la Grèce et l'Italie sont situées sous de beaux ciels*, Greece and Italy are situated beneath beautiful skies; (*c*) *des ciels de lit*, bed testers.

(*d*) *Œil*, eye, usually has the plural *yeux*: *elle a de beaux yeux*, she has beautiful eyes. In compound words in which it is used figuratively, it forms its plural regularly: *des œils-de-bœuf*, bullseye windows; *des œils-de-chat*, catseyes (precious stones).

(*e*) *Travail*, when it means work, has the plural *travaux*: *des travaux manuels*, manual labour. When used in the sense (*a*) of a brake for shoeing vicious horses, or (*b*) of official reports to the head of a department, it forms its plural regularly.

(*f*) *Bétail* has no plural, and *bestiaux* has no singular. Both mean cattle, and may be used to supplement each other.

8. Some nouns have one meaning in the singular and two meanings in the plural. The most usual of these are: *une arme*, weapon, *des armes*, weapons, and coat of arms; *un arrêt*, stoppage, *des arrêts*, stoppages, and arrests; *le ciseau*, chisel, *les ciseaux*, chisels and scissors; *la défense*, defence, *les défenses*, defences, and tusks; *le fer*, iron, *les fers*, different kinds of iron, and fetters; *la lunette*, telescope, *les lunettes*, telescopes, and spectacles.

9. Some nouns are used only in the plural. The most common of them are:

les agrès (m.), rigging
les alentours (m.), surroundings
les broussailles (f.), brushwood
les décombres (m.), rubbish
les dépens (m.), costs
environs (m.), environs
fiançailles (f.), betrothal
frais (m.), expenses
funérailles (f.), funeral
immondices (f.), filth
matériaux (m.), material
mœurs (f.), morals, manners
obsèques (f.), obsequies
ténèbres (f.), darkness
vivres (m.), provisions

EXERCISE VII.

1. There are some beautiful books.
2. The children are polite.
3. You have some fine oranges.
4. Boats have rudders.
5. Peaches (*pêche*) and apricots have stones.
6. We have given prizes (*prix*) to the pupils (*élève*).
7. The doors have no bolts.
8. The children's toys are broken (*cassé*).
9. The princess's jewels have cost (*coûté*) exorbitant prices.
10. There are some cabbages in the garden.
11. The shepherds (*berger*) tend (*gardent*) the flocks (*troupeau*).
12. Horses are useful animals.
13. There are no jackals in England (*Angleterre*).
14. The churches (*église*) have beautiful stained-glass windows.
15. The generals have noble ancestors.
16. We have no need of fans.
17. The little girls have blue eyes (the eyes blue).
18. They have given several (*plusieurs*) balls.
19. The vault of the heavens is strewn with (*parsemée de*) stars (*étoile*).
20. The works of men are perishable (*périssable*).

KEY TO EXERCISE V. (page 907)

1. Il y a quatre saisons: le printemps, l'été l'automne, et l'hiver. 2. Le printemps est la première saison de l'année. 3. L'hiver n'est pas la saison des fleurs. 4. En été il n'y a pas de neige. 5. Le mois de Décembre est un des mois de l'hiver. 6. La pomme est le fruit du pommier. 7. Le rosier n'a pas des fruits. 8. Le chêne est un arbre, la bruyère est un arbrisseau. 9. Il y a un hêtre et une aubépine derrière la maison. 10. Il a une prune, elle a un abricot, et nous avons des cerises. 11. Il y a un oiseau dans la cage. 12. Les enfants sont sur la plage. 13. Le frère et la sœur ont la rougeole. 14. J'ai une migraine. 15. Le mensonge est un vice. 16. La sentinelle n'est pas une recrue. 17. Il y a une gravure sur la première page du livre. 18. J'écris avec la craie. 19. Le marin et le mousse aiment la mer. 20. La fin de la leçon.

By P. G. Konody and Dr. Osten

Gender of Nouns, Adjectives, etc.

XII. Of FEMININE GENDER are:

(*a*) Substantives denoting female persons [see VII. 1].

(*b*) Many animals of both sexes.

(*c*) Nouns ending in -ei, -eit, ſchaft, ung, and -ucht.

(*d*) The names of most trees, except compounds with -Baum (*m.*) tree, which are always masculine [see XII. 2].

(*e*) Inanimate objects ending in e.

(*f*) Such words ending in in, as are formed from the correlative masculine by the addition of this suffix which denotes the female gender. (Masculine nouns ending in -e in this case drop this letter, and in some cases the stem vowel is modified.) Der König, the king; die König-in, the queen; der Graf, the count; die Gräf-in, the countess; der Löwe, the lion; die Löw-in, the lioness; der Hund, the dog; die Hünd-in, the bitch; der Franzo'ſe, the Frenchman, die Franzoſ'-in*, the Frenchwoman; der Bauer, the peasant, die Bäu'er-in, the peasant-woman.

(*g*) The wives of persons with academical and certain professional titles are generally addressed with feminised modifications of these titles. The wife of a doctor, professor, parson, councillor, major, etc., is addressed as Frau Doctor-in, Profeſſor-in, Pfar'rer-in (der Pfarrer, the parson), Räth-in (der Rath, the councillor), Major'-in.

(*h*) The names of a few countries, which are always used with the definite article

EXAMPLES: (*a*) die Tochter, the daughter; die Schweſter, the sister.

(*b*) die Lerche, the lark; die Hyäne, the hyena.

(*c*) die Schmeichelei', flattery; die Frei'heit, liberty; die Freu'ndſchaft, friendship; die Eri'nnerung, remembrance; die Schlucht, the gorge, ravine.

(*d*) die Eiche, the oak (but der Eichbaum, the oak tree); die Pappel, the poplar; die Lärche, the larch; die Fichte, the pine.

(*e*) die Tinte, the ink; die Roſe, the rose; die Güte, the kindness, etc. EXCEPTIONS: der Käſe, the cheese; das Auge, the eye.

(*h*) die Türkei', Turkey; die Schweiz, Switzerland; die Krim, the Crimea; die Mol'dau, Moldavia; die Wallachei', Wallachia, etc.

Of NEUTER GENDER are:

1. (*a*) All words which are not substantives, but are used substantively, and are therefore written with capitals.

(*b*) The names of some countries and towns, which take the article das when preceded by adjectives.

(*c*) All diminutives ending in -chen and -lein. [See VII.].

(*d*) Most nouns ending in -nis, ſal, and tum.

(*e*) Many metals.

(*f*) The majority of collective nouns with the prefix Ge-.

EXAMPLES: (*a*) das Tanzen (infinitive of a verb with a capital), the (act of) dancing; das Erha'bene, the sublime (adjective used substantively); das Viel'fache, the manifold (indefinite numeral), etc.

(*b*) das ſo'nnige Ita'lien, sunny Italy; das ne'belige England, foggy England; das unerme'ßliche London, immense London; das reiche Hamburg, rich Hamburg.

(*c*) das Brü'derchen (diminutive of der Bruder), das Mütterlein (dimin. of die Mutter), das Blü'melein or das Blümchen (dimin. of die Blume, the flower).

(*d*) das Hin'dernis, the obstacle; das Schick'ſal, the fate; das Hei'ligtum, the sanctuary. EXCEPTIONS: die Ke'nntnis, (*f.*) the knowledge; die Drangſal (*f.*), the affliction, trouble; der Reichtum (*m.*) wealth; and a few others.

(*e*) das Eiſen, iron; das Blei, lead; das Kupfer, copper; das Silber, silver. EXCEPTION: der Stahl, steel.

(*f*) das Gebir'ge, the mountain range; das Gefo'lge, the retinue; das Gewölk', the clouds, etc. But there are also many EXCEPTIONS; for instance: die Gemein'de (*f.*), the community; der Geſang' (*m.*), the singing, song.

2. COMPOUND NOUNS take their gender from their last component—*e. g.*, der Poſt'bote (*m.*) the postman, [die Poſt (*f.*) and der Bote (*m.*) messenger]; die Brief'taube (*f.*) the carrier-pigeon, [der Brief (*m.*) letter, and die Taube (*f.*) pigeon, dove]; das Gar'tenfeſt (*n.*) the garden party, [der Garten (*m.*) and das Feſt (*n.*) the festivity]. In some compound words an e or s is inserted for the sake of euphony.

3. COMPOUNDS OF ADJECTIVES OR PREPOSITIONS WITH SUBSTANTIVES generally take the gender of the substantive, but there are exceptions to this rule; for instance: die An'mut (*f.*) the grace, [der Mut (*m.*) courage]; die Sanftmut (*f.*) gentleness, tenderness [ſanft, gentle, and der Mut]; der Ab'ſcheu (*m.*) the aversion, [die Scheu (*f.*) bashfulness].

4. A few substantives have two genders which can be used indiscriminately; for instance; der (*m.*) or das (*n.*) Me'ter (the metre), Liter (litre), Thermome'ter, Barome'ter, Scepter (sceptre); die (*f.*) or das (*n.*) Verderb'nis, corruption, depravity; der or die Hausflur, lobby, entrance hall; der or das Un'geſtüm, impetuosity, etc.

5. The following substantives change their meaning with the gender:

---

* EXCEPTION: Der Deutſche, the German, die Deutſche (*not* die Deutſchin), the German woman.

r Band (*m.*) volume [of a book]	das Band (*n.*) ribbon
, Bauer (*m.*) peasant	,, Bauer (*n.*) [bird-] cage
, Bund (*m.*) league	,, Bund (*n.*) bundle
, Chor (*m.*) choral-song, or chorus	,, Chor (*n.*) locality in the church for the choir
, Erbe (*m.*) heir	,, Erbe (*n.*) inheritance
e Erkenntnis (*f*) insight	,, Erkenntnis (*n.*) judicial verdict
r Gehalt (*m.*) contents	,, Gehalt (*n.*) salary
Geißel (*m.*) hostage	die Geißel (*f.*) scourge
, Haft (*m.*) clasp	,, Haft (*f.*) prison, custody
Harz (*m.*) Harz Mountains	das Harz (*n.*) resin, gum of trees
Heide (*m.*) heathen	die Heide (*f.*) heath
, Hut (*m.*) hat	,, Hut (*f.*) heed, guard
, Kiefer (*m.*) jaw	,, Kiefer (*f.*) fir
, Kunde (*m.*) customer	,, Kunde (*f.*) news intelligence
, Leiter (*m.*) manager, guide	,, Leiter (*f.*) ladder
e Mark (*f.*) province, boundary, Germ. coin	das Mark (*n.*) marrow
r Menſch (*m.*) man	,, Menſch (*n.*) wench, hussy
Meſſer (*m.*) measurer	,, Meſſer (*n.*) knife
Reis (*m.*) rice	,, Reis (*n.*) sprig, twig
, Schild (*m.*) shield	,, Schild (*n.*) sign—board
, See (*m.*) lake	die See (*f.*) sea
Sproſſe (*m.*) offspring	,, Sproſſe (*f.*) step of a ladder
e Steuer, (*f.*) rate, tax	das Steuer (*n.*) helm, rudder
r Stift (*m.*) pencil	,, Stift (*n.*) monastery, chapter
, Teil (*m.*) part	,, Teil (*n.*) due, share
Thor (*m*) fool	,, Thor (*n.*) gate
Verdienſt (*m.*) gain, profit, earnings	,, Verdienſt (*n.*) merit
- Wehr (*f.*) defence	,, Wehr (*n.*) weir, dyke, ditch

Inflections of Weak Verbs

XIII. In the IMPERFECT a *weak verb* se X.] takes the following inflections:

INDICATIVE.

Singular

1.	-ete or -te	ich lob-te	I praised
2.	-eteſt or -teſt	du lob-teſt	thou praisedst
3.	-ete or -te	er lob-te	he praised

Plural

1.	-eten or -ten	wir lob-ten	we praised
2.	-etet or -tet	ihr lob-tet	you ,,
3.	-eten or -ten	ſie lob-ten	they ,,

1. The inflections of the conjunctive are identical with those of the indicative.
2. The first -e of the inflections -ete, -eteſt, etc. is generally dropped, but retained for euphony's sake in verbs with stems ending in -d, -n, -ſt, -t; like: bad-en, to bathe; athm-en, to breathe; koſt-en, to cost or to taste; wart-en, to wait; (1. *sing.* ich bad-ete; 2. du athmet-eſt; 3. er koſt-ete; 1. *plur.* wir wart-eten, etc.). For the same reason the first e of the inflections is sometimes dropped, sometimes retained, in verbs with stems ending in -n. Thus it is dropped in ahn-en, to forebode; gähn-en, to yawn; lern-en, to learn, etc., and retained in öffn-en, to open; rechn-en, to reckon; zeichn-en, to draw or design. (1. *sing.* ich ahn-te; 2. du gähn-teſt; 3. er lern-te; but 1. *plur.* wir öffn-eten; 2. ihr rechn-etet; 3. ſie zeichn-eten).

The IMPERFECT is the distinguishing trait of the weak and strong conjugations [see X_1]. Weak verbs form this tense by taking suffixes, strong verbs by changing the stem vowel. Reden (stem: red-) and ſprechen (stem: ſprech-)—either of which signifies, to speak—form the imperfect: ich red-ete (weak) I spoke, and ich ſprach (strong) I spoke, the latter merely changing the stem vowel e into a.

EXAMINATION PAPER IV.

1. What is the usual gender of trees, and under which conditions is it changed?
2. How are feminine nouns formed from masculine nouns which have no separate feminine correlative?
3. What is the gender of nouns terminating in e, and indicating inanimate objects? Are there any exceptions?
4. What is the gender of nouns which are not substantives, but are used substantively?
5. Which nationality is exempt from the rule referred to in question 2?
6. Which gender is taken by compound substantives?
7. Which letters are sometimes inserted between the components of a compound noun, and why?
8. By which tense is it easiest to recognise whether a verb belongs to the weak or to the strong conjugation?

2. In which cases is the first e of the inflections of the weak imperfect retained?

10. Which is the most characteristic feature of the strong imperfect?

11. Are there any differences in the inflections of the weak imperfect in the indicative and in the conjunctive?

12. For what reasons is the first e in the inflections of the weak imperfect frequently dropped?

EXERCISE 1.* Insert the missing articles, verbs and nouns.

. . . . Tante redet mit . . . . Nichte; . . . . Schweſter
The aunt speaks to the niece; the sister
. . . . . Mädchens iſt ſchön; ich liebe . . . . Eiche,
of the girl is pretty; I love the oak,
. . . Pappel, und . . . Kaſtanien-Baum; . . . Höflichkeit
the poplar, and the chestnut(-tree); the civility

---

* To avoid confusion, the German phraseology has been adopted for the English translation of German sentences, so that each English word is placed under its German equivalent.

. . . . . . Engländers iſt bekannt; . . . Erinnerung iſt
of the Englishman is known; remembrance is
. . . Prüfſtein (see VII. b and XII. 2) . . . Vergangenheit;
the touchstone of the past;
. . . . Wieſe war grün und . . . . Heide braun:
the meadow was green and the heath brown:
. . . . . Käſe iſt friſch.
the cheese is fresh.

. . . . Fürſt ſchreibt; . . . . lobte . . . .
the prince writes; the princess praised the
Kinder; . . . Baron und . . . . kommen heute;
children; the baron and the baroness come to-day;
. . . Wolf und . . . . Fuchs und . . .
the wolf and the she-wolf, the fox and the
. . . . . ſind Raubthiere; . . . . Blüm'chen
she-fox are beasts of prey; the little flower (dimin.)
blüht; . . . . Vöglein ſingt;
blossoms; the little bird (dimin.) sings;
Finſternis war undurchdringlich; . . . Heldentum
the darkness was impenetrable; the heroism
. . . Griechen; . . . Gold und . . . Silber . . . Metalle;
of the Greeks; gold and silver are metals;
. . . alte . . . Zinn iſt heutzutage werthvoll; . . . Stahl . . . .
old tin is nowadays valuable; the steel of the
Degens . . . . biegſam; . . . . Geſchick . . . . Mannes
sword was pliable; the fate of the man
erweckte . . . Gefühl . . . Mitleids; . . . Geſang
awakens the sentiment of pity; the singing
. . . . Gemeinde und . . . . Gebet . . . . Pfarrers
of the community and the prayer of the parson
waren hörbar.
were audible.

Exercise 2. Form compound nouns with their articles from the substantives:

Der Wald, the wood (forest); die Quelle, the source: Waldquelle. Der Bach, the brook; die Forelle, the trout: Bachforelle. Die Forelle, der Bach: Forellenbach. Der Vogel, the bird; das Neſt, the nest: Vogelneſt. Das Neſt, der Vogel: Neſtvogel. Der Berg, the mountain; die Kette, the ridge (or chain): Bergkette, the ridge or chain of mountains. Die Hand, the hand; der Schuh, the shoe: Handſchuh, the glove.

Exercise 3. Insert the different articles of the consonant substantives with different meaning:

. . . . See iſt oft ſo wild wie . . . . See; . .
the lake is often as rough as the sea; the
Kunde erreichte . . . Kunden; . . . Verdienſt
intelligence reached the customer; merit
und . . Verdienſt begegnen einander nicht immer;
and gain meet (each other) not always;
(do not always meet)
. . . . Erkenntniß zeigt . . . Erkenntniß des Richters;
the judicial verdict shows the insight of the judge;
. . . Thoren kommen durch . . . . Thor des Gartens
the fools come through the gate of the garden.

Exercise 4. Add to the stem the conjugational inflections:

Ich reiſ . . . mit ihm; wir wander . . .* durch den
I travelled with him; we walked through the
Garten; ſie zeichn . . fleißig; Sie zeichn . . ein Bild;
garden; you drew diligently; you drew a picture;
ſie liebt . . einander zärtlich; ſie liebt . . den
they loved each other tenderly; she loved the
Vater; wir atm . . . . . kaum; er rechn . . . laut;
father; we breathed scarcely; he reckoned aloud;
du arbeit . . . und blick . . .* nicht nach mir; ſie wart . .
you worked and glanced not at me; she waited
und wander . . dann fort; du erzähl . . .* die
and walked then away: you narrated the
Einzelheiten, die Mutter ſtrick . .*, wir arbeit . . . .,
particulars, the mother knitted, we worked,
ſie rechn . . . . ., die Kinder ſpiel . . .*, nur der
you calculated, the children played, only the
Vater fehl . . . ; er . . . . nicht daheim.
father was missing; he was not at home.

* wander:n, to walk, wander; blick:en, to look, glance; erzähl:en, to narrate; ſtrick:en, to knit; ſpiel:en, to play.

THE STREAM OF LIFE

How the Blood Circulates. Action of the Heart, Arteries, Capillaries and Veins. Pulsation. Vascular Glands. Lymphatic System

By Dr. A. T. SCHOFIELD

WE have considered the whole system of vessels, large and small, that convey the blood to every part of the body, and examined the wonderful pump by means of which the life stream is propelled once round the body every minute. All this can, of course, be looked at after death ; and if any student is interested enough to verify the facts we have described, and shall describe, in this course, an admirable way of doing so is to buy a skinned rabbit that has not had its internal organs removed, and then, with a common pen-knife and a pair of forceps, the leading facts of anatomy can, with little trouble, be clearly made out ; and although the arrangement in a rabbit is not exactly that of a human being, it is quite near enough for all practical purposes.

The Blood in Circulation. But now we have to follow mentally what cannot be seen by dissection—and that is, the blood in actual circulation.

The best way is to begin with the heart and follow the course of the blood through the various chambers there, bearing in mind at the outset one or two leading facts. The blood enters the heart on the right side, and finally leaves it for the body on the left. The right heart is always full of bluish, or venous, blood ; the left of bright red, or arterial, blood.

The actual movement through the heart, then, is as follows: The two upper chambers communicate with the lower by means of folding doors or valves, but there is no opening between the right and the left sides of the heart.

The Heart an Automatic Pump. The blood arrives at the right side of the heart by the two large veins from the upper and lower parts of the body. Just before the inferior vena cava, or lower vein, reaches the heart, it receives its fresh supply of food by a large vessel from the liver that opens into it ; and just before the superior vena cava, or upper vein, reaches the heart, it receives all the chyle, or digested fat, together with the purified lymph, from the body, so that the venous blood which pours into the heart is not the same as that which left the capillaries, but has already received its fresh supplies of nourishment. All it now wants is the oxygen from the fresh air to restore its bright colour. The blood enters the heart by the *right auricle*, and pours down through the open valve in the floor into the *right ventricle* below. As this fills with blood, the flaps of the valve—three in number (hence it is called the tricuspid valve, because it has three cusps, or flaps)—float up on the blood and close together gradually. When the right ventricle is quite full, the heart contracts forcibly, and all the blood is forced out of the ventricle, through another valve with three flaps, along a short artery called the pulmonary, or lung artery, because it takes the blood to the lungs to be charged with fresh air. It then passes through the innumerable lung capillaries.

When the blood has received its supply of oxygen, it returns by *four vessels*, called the pulmonary veins, to the *left auricle*. It pours through the valve in the floor (which is called the mitral valve, because it is like a bishop's mitre, and has only two flaps, or cusps) into the *left ventricle*. As this fills, the cusps of the mitral valve are floated up and closed. The heart then contracts vigorously (at the same time as on the right side) by sudden muscular action of the walls (which are over half an inch thick) and forces all the blood through another valve with three flaps, called the aortic valve, into the aorta. This squeezing of the heart can only drive the blood in one direction, on account of the valves. If you get an indiarubber syringe, which has a ball to squeeze in the middle, and a tube at each end [55], and put the shorter end into water and squeeze, as the ball expands again it sucks the water in to fill the ball ; and then, as you squeeze it again, a valve prevents the water being forced back, and it rushes along the other pipe and comes out in a jet. The short pipe in the water may represent the veins, the ball the heart, and the other pipe, out of which the water flows, the arteries.

Pulsation. The contraction of the heart we call the beat, and it occurs about seventy times a minute, and gives the throb, or pulsation, to the blood in the arteries ; this flows in jerks (as you see when one is cut), while the blood in veins flows in a slow and steady stream.

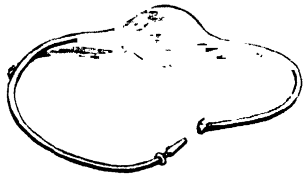
The Greater and Lesser Circulations. We thus see there are two principal circulations—one called the systemic, or *greater, circulation*, that circulates through the system or body ; and the other the pulmonary, or *lesser, circulation*, that circulates through the lungs. In the former the blood *loses* oxygen, gains *carbonic acid*, and becomes dark and impure ; in the latter the blood *loses carbonic acid*, gains *oxygen*, and becomes bright and pure.

The strength of the beat of the left ventricle is double that of the right, and the whole force exerted by the heart is equal to 120 tons lifted one foot high, or the heart's own weight raised 20,000 ft. every hour. The greatest height an active man can raise himself is 1,000 ft. an hour ; a locomotive can raise itself nearly 3,000 ft., while the heart raises itself higher than Mont Blanc.

How the Heart Rests. There is an idea that the heart is more incessantly at work than other organs. Such is not the case, but the periods of rest alternate much more rapidly. All working parts of the body have their intervals of rest—the brain when we sleep; the stomach, eyelids, diaphragm, etc., at shorter intervals.

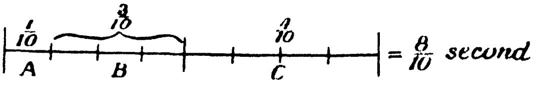
If the whole circle of the heart's action be completed in $\frac{8}{10}$ of a second, half of this is rest, as is represented in 56. The contraction of the heart is called the *systole*, the rest the *diastole*.

The movements of the heart are mainly caused by three sets of ganglia in the heart itself. With proper care, a heart can therefore beat when out of the body altogether, and even when cut in three pieces, each of which includes one of these ganglia, or nerve centres.



55. SYRINGE ILLUSTRATING ACTION OF THE HEART AND VALVES

Arterial Circulation. Passing on now to the course of the blood in the arteries, we must remember that we have not here to deal with a series of rigid pipes, but highly elastic tubes. This elasticity is a very important property in more ways than one. In the first place, the beat of the heart on the injection of four tablespoonfuls of blood into the aorta is intermittent, and takes place about seventy times a minute, or at least every second. Now, such is the force of the automatic pump we call the heart that, as we have said, it lifts its own weight higher than Mont Blanc every hour. This force, if an artery were a rigid tube like a gas-pipe, would draw the blood along in jerks at about 200 ft. a second. As it is, the force first of all distends the elastic artery so that you can feel it swelling beneath the finger at the wrists, and can also often notice it with the eye there, and at the temples. Then, in the intervals between the beats, the contraction of the overstretched artery still keeps up the pressure on the blood, and forces it along the vessel, converting by this means an intermittent propelling power of 200 ft. a second into a steady flow of about 1 ft. a second, which is the average arterial speed of the blood until the capillaries are reached. We have already stated that if the arterial calibre be represented by a tube 1 in. in diameter, that of the united capillaries would be about 2 ft., or nearly 600 times as great.



56 ONE BEAT OF THE HEART

A. Auricular Systole = $\frac{1}{10}$ sec. *B*. Ventricular Systole = $\frac{3}{10}$ sec. *C*. Diastole, or pause = $\frac{4}{10}$ sec.

The Rush of the Blood Checked. Here, then, the rush of the blood is completely checked. It is like a river flowing into a lake, and not only into a lake, but into a network of tiny channels equal in size to a lake, and involving loss of power by friction against their million walls. All this reduces the blood speed from 1 ft. a second to 1 in. a minute. On this retardation, as we have shown, our life depends. It is useless whisking food at 60 miles an hour past our doors. It is all very well to bring it up at this speed from all parts of the country; but when it has to be distributed in towns we no longer use trains at 60 miles an hour, but butchers' and bakers' carts that stop and deliver at every door; we should die of starvation otherwise. A parallel case occurs here. The air and food cannot be brought too quickly to the populous cell towns; but once there it is carried slowly from door to door that each may take his share, and all be satisfied. So far, from all we have said, it might be supposed that the process is simply mechanical. A well-made pump beating ever at 70 strokes a minute forces the blood into miles of tiny tubes, through which it circulates at a fixed rate. But such is not the case. In the first place the circulation in the arterial system depends, of course, upon the heart's beat; but this is by no means uniform nor equally forcible, for in its turn it is controlled from the lower brain by an intelligent force often termed "Nature," but which I call the unconscious mind. The control may be partly reflex—that is, the result of stimuli; but those who have thought more on the subject are convinced that even in reflex action there is something more than mere mechanism, that some power beyond matter is at work—there is the directing agent of mind.

Action of the Capillaries. Once, however, the capillaries are reached the power that controls the movement of the blood is no longer the heart force with which it is propelled, but the opening or closing of the channels through which it has to flow. There is, as we shall see when we study the nervous system, and as we have briefly pointed out in speaking of assimilation, a central power that controls absolutely the opening and closing of the miles of capillaries in the body, so that they are incessantly varying according to the changing needs of the economy, and its requirements not only of food but of heat. For we must ever remember that this great circulation of hot food through the body not only feeds it but warms it.

We cannot here go into the wonderful way in which whole tracts of capillaries are thus incessantly being opened and closed according to the body's needs. Suffice it to say the process is so remarkable, and so beyond mere mechanism, that were there no other indication of a central intelligent controlling force, this would suffice.

We need not linger longer on the passage of the blood through these tiny channels, for the section on assimilation has covered the same ground

The Blood in the Veins. When we come to the veins we find for the first time the circulation begins to be in difficulties. It is easy to drive the blood from the heart to the capillaries, say, of the great toe: the difficulty is to get it back again. It is in every sense uphill work, for the force of the heart is well-nigh spent as far as direct impulse goes, owing to the passage through the capillaries; but still a certain compulsion from behind remains to help the blood, now venous in colour and quality, back to the heart.

Exercise Aids Circulation. The second help that comes into play arises from the fact that the walls of the veins are thinner than the arteries, and as they are placed between the large muscles in many cases, muscular contraction in the exercise of arms and legs squeezes these veins so forcibly as almost to act as another pump. Of course a moment's reflection will show that squeezing a pipe alone does not propel the contents—it simply forces some portion back and some a little forward. Valves are required that open towards the heart, but cannot be opened backwards, and these, as we have seen, the veins possess; so that every squeeze can only move the blood in one direction, and that is towards the heart. Here we see the great value of exercise in aiding the venous circulation. Without it the venous blood tends to stagnate, and all the vital processes are retarded as the circulation becomes enfeebled.

The Part Played by Respiration. The next help the circulation gets is from the respiration, in which the pressure on the large blood-vessels and heart is withdrawn, and then the blood is sucked up towards that organ. The factors, then, that bring the blood back from the capillaries to the heart are: (1) The heart's beat; (2) the thinness of the veins; (3) the squeezing by muscle contraction; (4) the valves; (5) respiration. And thus in almost one minute the blood flows from the left to the right side of the heart.

When the Blood Leaves the Heart. Blood, when it leaves the heart, has its choice of one of five courses. This is briefly described in the diagram [57].

The *shortest* is round the walls of the heart itself to nourish its muscles, starting from the left side and returning through the right veins. This is called the *coronary* circulation.

The *next* longer is from the pulmonary artery in the right side of the heart through the lungs and back to the left side of the heart by the four pulmonary veins. This is called the *pulmonary* circulation.

The second longer is from the left side of the heart through the walls of the digestive organs and kidneys, receiving the food and carrying it into the liver and also getting rid of any refuse, and flowing back to the right side of the heart. This is called the *digestive* circulation.

The *third* longer is from the left side of the heart through the brain by special capillaries and veins that cannot close, which we shall describe later, and so back to the right side of the heart. This is called the *cerebral* circulation.

The *last* and longest is through every part of the body, and this is the *systemic* circulation, and has been already described.

What is the Pulse? The pulse is not the actual flow of the blood, which would certainly appear to be intermittent, as indeed it is, when it spurts out of a cut artery. In the closed artery, however, it is not, as we have shown, intermittent, but is steady, owing to the pressure of the blood in front and the give of the elastic arterial walls. The pulse is the wave sent along the blood by the beat of the heart, by the forcing into the aorta of the fresh supply of blood. This wave passes down the blood-stream, stretching the wall of the artery as it travels along twenty-eight times as fast as the blood itself flows. The pulse, therefore, at the wrist is almost simultaneous with the beat of the heart, which it could not possibly be if it were the flow of blood that caused it.

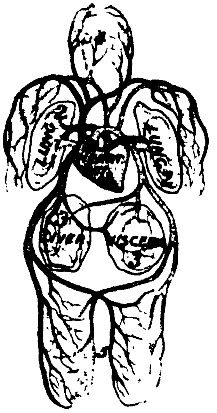
Besides its elasticity the artery has also the muscular coat, which in the smaller vessels adjusts the amount of blood to the state of the capillaries (whether open or shut), so that there may be no sudden block. This nice adaptation of the size of the vessel to the amount of blood in it is called "tone," and the loss of tone in an artery shows either languor of central controlling power (nerve exhaustion), or failure of elasticity (age, disease, etc.), or the formation in the arterial walls of hard plates (gout, etc.), all interfering with the regularity of the circulation.

The pulse is not only at the wrist, but wherever an artery is near enough to the surface for the wave of the pulse to be felt or seen, as at the temples, the ankles, etc.

We may just state that generally the influences that slow down the circulation are cold, digitalis, and the pneumogastric nerve, whereas heat, atropine, and the sympathetic nerve accelerate it. The vaso-motor nerve opens and closes the capillaries, and these act harmoniously, not only with arteries, but with the nerves controlling the heart.

The Vascular Glands. As indirectly connected with the vascular system, we may here consider the vascular glands, which include the spleen, the thyroid and the thymus glands in the thorax; and the suprarenal capsules above the kidneys.

The *spleen* is about the size and shape of the palm of the owner's hand, and is situated beneath the ninth, tenth, and eleventh ribs in the left side beneath the diaphragm. Its convex side is outward and its concave is in close proximity with the tail of the pancreas. It is of a deep red colour, full of blood, and weighs about half a pound. It is credited with many functions, one being that of a storehouse of peptones, and



57. DIAGRAM SHOWING THE FIVE COURSES OF THE CIRCULATION

(1) Round the heart, (2) to the lungs, (3) in the digestive organs, (4) in the brain, and (5) over the body. Dark shading, venous blood. Light shading, arterial blood

there is no doubt that a storehouse is sorely wanted by great meat-eaters. The red corpuscles of the blood are also said to be born here and introduced into the blood in great numbers, and then broken up and taken out when they want to die. The spleen is greatly enlarged in ague and other diseases.

The *thyroid gland* consists of two lobes, united by a band and lying in front of the larnyx, or throat. It weighs normally 1½ ounces, but, like the spleen, may be greatly enlarged in disease. It contains a gummy material, the purport of which is not readily ascertained. When it is diseased, the mental faculties seem affected. The Derbyshire neck or goitre is an enlargement of this gland.

The *thymus gland* is an inch long, lying lower down at birth on each side of the windpipe, but disappearing very early in life. It may form red corpuscles, like the spleen.

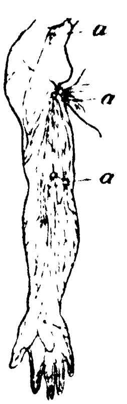
The *suprarenal capsules* are two small bodies like cocked hats, one on the top of each kidney, and seem to serve a remarkable purpose. The extract obtained from them has a marvellous power of contracting capillaries and stopping the flow of blood, and is now extensively used in arresting hæmorrhage. Its power is wonderful, and we have nothing so efficacious in drugs. When these suprarenal capsules are diseased the whole skin gets the colour of bronze. There is no doubt that they exercise a powerful influence over the economy of the body, and further discoveries may tell us exactly what this is.

The Lymphatic System. We now turn to a brief description of the lymphatic system, a small portion of which only has been touched upon in describing the digestion of fat.

It will be remembered that at the outset we pointed out that, as beneath our streets are three sets of pipes conveying gas, water, and sewerage, so throughout the body are three descriptions of vessels coloured by the fluid they contain red, blue, and white. The red and blue we have considered—they convey the arterial and the venous blood. The white or colourless are the lymphatics, which form a system almost as large as the true vascular system, of which they are an appendage, and with which they are everywhere connected. We must understand, then, that within the whole of the tissues of the body surrounding all the capillaries, and existing wherever there are no blood-vessels, is a vast network of tubes containing the liquid drainage of the body, which flows through all those vessels, always towards the heart. The lymph capillaries collect into large lymphatics, and eventually enter two trunks, the right thoracic duct, which is small, and the left thoracic duct, which is very much larger, and which carries all the fat from the food; these enter the veins on each side of the root of the neck. Just as all the body cells and tissues are being continually irrigated by capillaries, whose thin walls allow the fluid to ooze through, so they are constantly being drained of the surplus fluid by the lymphatics [58].

Besides this general use, the lymphatics have at least two other special functions.

1. They act in the intestines by the agency of the lacteals as absorbents of "fat" food and in the formation of chyle.



58. THE LYMPHATIC VESSELS IN THE ARM

(*a*) Lymphatic Glands

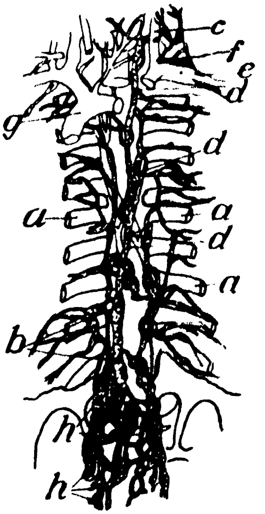
2. In some tissues they form the sole source of nourishment, as in the cornea of the eye, and in many connective tissues, which have no blood circulation.

The whole system may be regarded as a necessary appendage to the vascular system, although we have treated part of it under the head of absorption in order to complete the history of food disgestion.

The lymphatics that commence as capillaries round the blood-vessels have very thin and irregular walls, and often appear mere channels hollowed out in the surrounding tissues.

The lymph is the agent in conveying the oxygen and food from the blood capillaries, which they surround, to the body cells, as well as in conveying the major part of the excreta, CO_2, urea, etc., from these into blood.

Movement of the Lymph. The movement of the lymph towards the heart is first due to muscular pressure and very numerous valves. The collapsible lymphatics, whether amongst the voluntary muscles of the neck or the unstriped muscles of the intestine, have their contents therefore propelled in one

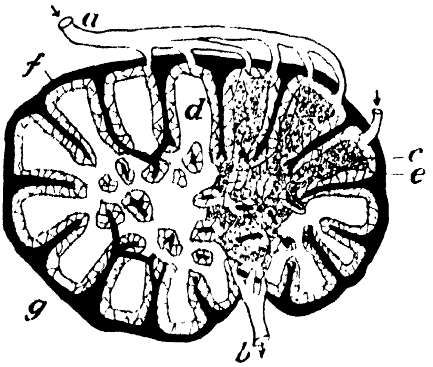


59. THORACIC DUCT

(*a*) Ribs; (*b*) receptaculum chyli; (*c*) left jugular vein; (*d*) trunk of thoracic duct; (*e*) left subclavian vein; (*f*) junction of these two veins, showing entrance of thoracic duct; (*g*) superior vena cava; (*h*) lymphatic glands direction. A second force is the direct act of the muscles surrounding each lacteal in the villi, by which, when full, their contents are ejected into the vessels beneath, valves again preventing their return. A third force is the inspiratory movement of the chest (as in the veins) which both squeezes fluid into the lymphatics and sucks the fluid of the large ducts into the blood-stream.

The lymphatics of the body, with the exception of some on the right side, but including all the lacteals, discharge their contents—after passing through numerous lymphatic glands en route—into a large reservoir about 2 in. long, called the *receptaculum chyli* [59] lying in the abdomen at the lower part of the spine on the left side. From here a stout tube, as thick as a goose-quill and about 18 in. length, called the *left thoracic duct*, leads right up the left side, and empties its contents at the juncture of the neck and arm (jugular and subclavian veins), thence to be carried to the right side of the heart.

The Police of the Body. Nearly all the lymph before entering the blood has to pass through one or more lymphatic glands. These are found in great numbers in the trunk of the body, in the neck, armpit, and groin, but not further down the limbs than the elbow or knee. These glands are somewhat the shape of small beans, lying right across the path of the lymphatics, with the convex side outwards or downwards, along which the lymphatics enter, while the lymph leaves it at the hilum, or depression, on the other side by one or two larger vessels [60].



60. SECTION OF A LYMPHATIC GLAND

(*a*) Afferent, (*b*) efferent lymphatics; (*c*) lymphoid tissue; (*d*) cortical substance; (*e*) lymph-path; (*f*) fibrous capsule sending in divisions into (*g*) the substance of the gland

The lymphatic glands exercise most important functions in the economy. They may be said to represent the police of the body, and every suspicious substance that enters the body finds its way to them sooner or later, and is there detained.

They stop, as far as they are able, the circulation of all poisons in the system; but for them a poisoned finger would infallibly infect the whole body. Yet, thanks to a small gland at the bend of the elbow, or, if this fail, the extensive chain of glands in the armpit, the poison is arrested and destroyed. We are constantly poisoning ourselves in small ways, and many of the poisons would spread and become fatal were it not for the action of these glands. Sometimes the head or throat, or ear or mouth is poisoned, and then it is that the poison is arrested and stopped and the life is saved by the lymphatic gland in the neck or throat; the glands swell and get painful, and we feel the lumps, which tell us the glands have done their work well. They are arranged all over the body at what may be called strategic points, and their value cannot be exaggerated.

In cancer of the breast, for instance, in the early stages when the poison is slight, it is stopped from entering the blood-stream by the glands in the armpit, which receive and destroy the poison, becoming enlarged and inflamed in the process. Should, however, the poison be allowed to progress undetected, there comes a time when its volume becomes too great, and it gets past them into the blood, and is there carried all over the body, and other centres of cancer are formed.

These lymphatic glands are filled with white corpuscles, similar to those in the blood, and it is these that destroy the poisons by breaking them up and reducing them to their elements.

All the drainage of the body, therefore, before it is poured into the blood, is carefully purified.

Before finally leaving this question of the circulation, we will give seven points that prove the truth of it—for this has often been doubted.

1. In half an hour the heart ejects more than the whole blood in the body.
2. Blood spurts from a cut artery.
3. The arteries are empty and the veins full after death.
4. If a limb be tied tightly with string, it becomes pale, because the arteries are compressed and blood cannot flow in; if tied slackly, it is swollen, because though blood can flow in, it cannot flow out.
5. The presence of valves in the veins.
6. Poison and aniline dyes are found to circulate.
7. The circulation can actually be seen during life in the web of a frog's foot.

FORAGE AND OTHER FARM CROPS

Lucerne, Sainfoin, Vetches, Clovers, Cabbage, Rape, Maize, Hops, Flax, and Hemp. Cultivation of Farm Crops

Group 1
AGRICULTURE
8

Continued from page 945

By Professor JAMES LONG

FORAGE CROPS

Lucerne. *M. Sativa* (Nat. ord., *Leguminosæ*; genus, *Medicago*), known as alfalfa in America, is a perennial, the roots of which have been traced to a depth of from 20 to 30 ft., for which reason on suitable soils it ignores drought [p. 881]. Lucerne is one of the very best forage crops; it produces superb hay, and may be cut four times annually after the first year, and until it has been overcome by weeds, which in course of seven years or so usually destroy the plant. Lucerne demands a dry, deep soil containing lime, and a mild climate; hence it is not grown in the North of England. It is a handsome plant, with a purplish-blue flower. It is sown with a corn crop in spring, 15 to 20 lb. of seed being drilled per acre. If broadcasted, more seed is required, but the plant is not so satisfactory. The weight of the seed is 64 lb. to the bushel. A useful crop will cut from 15 to 30 tons of green fodder, while as much as 5 tons of hay have been taken from an acre. Lucerne is occasionally mixed with grasses sown for a three or four years' ley, or permanent pasture.

Sainfoin. *O. sativa* (*Onobrychis*) is a handsome perennial, with a showy pink flower and a leaf with many leaflets [p. 881]. It is chiefly sown in the south on substantial chalky soils and other soils containing lime. Its roots penetrate to a great depth; it resists drought, and may last a few years. Sainfoin is a splendid green fodder, and is much employed for sheepfolding. The hay is equally approved by farmers, and is most valuable for horses and cattle. Sainfoin is usually drilled, the seed employed being either in the husk or removed from it by a process of milling. The seed required per acre is 50 lb. when milled, or 4 to 5 bushels in the husk. Milled seed weighs 62 lb. per bushel, seed in the husk about 25 lb.

SAINFOIN SEED

Vetches, or Tares. The vetch (*Vicia sativa*) is an annual grown in all parts of the country on most soils [p. 881]. It is sown at the rate of from 3 to 4 bushels per acre, the seed weighing 64 lb. to the bushel, either alone or with a cereal, preferably rye or oats. The mixture improves the feed, and the cereal plant keeps the vetch off the ground. Vetches are cut green for stock—especially horses—fed off by sheep folded upon them, employed for ensilage, and occasionally made into hay. There are two sub-varieties, the winter and the spring vetch, the former producing a very early cut of green food, while the latter provides forage during autumn, when it is often much needed. A green crop may weigh 10 to 14 tons per acre, while a dried crop may reach 30 to 40 cwt. The seeds number about 8,000 to the lb. The vetch is hardy, it responds to manure, and overcomes many weeds by its propensity to smother them.

Crimson Clover. Crimson clover (*Trifolium incarnatum*) is an annual, largely grown by the southern farmer for sheep feeding, and sometimes for hay [p. 941]. It suits most soils, upon which it is sown after the removal of a corn crop, the surface being well harrowed, and the seed broadcasted and covered with harrows and rolled. Ploughing for this crop is not advisable. Trifolium, of which there is a *white* variety (*T. album*), is really a catch crop, coming between a cereal and roots, or any other suitable crop which can be sown after its removal. It provides one of the earliest green fodders. The seed is sown at the rate of 12 to 20 lb. per acre, and weighs about 66 lb. per bushel, a green crop reaching 10 to 12 tons per acre.

Cabbage. *Brassica oleracea* (Nat. ord., *Cruciferæ*). There are different forms as there are several varieties of the cabbage tribe, including, as examples, the round-headed, big-hearted drumheads, the savoys, the loosely headed kale, or thousand-heads, and the flowering-hearted cauliflower. Although with good cultivation the cabbage will thrive on comparatively light soils, it prefers strong land, rich in nitrogen and phosphates. It responds best to dung and nitrate of soda, sometimes with an addition of salt. Field cabbage, which is a hardy biennial, like all members of the family, bears a yellow flower. Although frequently drilled, all the varieties of cabbage may be raised in seed-beds and transplanted. By adopting this method the plant will provide succulent green food for stock throughout at least six months of the year. The hardier members of the family are the kales, which are less damaged by frost and rain. Thousand-headed kale, grown largely for sheep, will produce a second crop after its foliage has once been consumed. The space required per plant is from 3 to 9 sq. ft., according to the variety and its size. The seed required to produce the plants for an acre is 1 to 1½ lb., or 3 lb. per acre when drilled. There are about 125,000 seeds to the lb., the weight of a bushel varying from 50 to 56 lb. A crop of drumheads should reach 25 to 35 tons to the acre.

Rape (*Brassica campestris*), like kohl-rabi and the cabbage, belongs to the natural order *Cruciferæ*, and is descended from the same stock. Rape is seldom sown in spring; it is chiefly a summer-sown crop intended for feeding sheep which are folded upon it, for ploughing-in as a green manure, or for smothering the weed crop. It is sometimes associated with mustard, the seed being mixed, and the two plants grown together with the same objects. The giant variety is most suitable for rich or well-manured soils, producing a great weight per acre, from 15 to 20 tons. The seed of the smaller variety is usually sown on chalks and the lighter soils; the quantity broadcasted is *12 lb. per acre, its weight being from 50 to 54 lb.* per bushel, the number of seeds in a lb. reaching nearly 120,000, while the yield of seed per acre should reach 30 bushels. Rape is often employed as a catch crop, whether for ploughing-in or feeding sheep, especially after the removal of an early crop of potatoes, being cleared off the land before the succeeding green crop is sown. Although rape will transplant, the practice is not common. The seed of rape, after pressing out the oil (colza), provides the residue from which rape-cake is manufactured.

THOUSAND-HEADED KALE

Mustard. There are two species of this plant—*Sinapis alba* and *S. nigra*. The former (white mustard) is that grown for forage, sometimes alone, often in combination with rape. It is, however, frequently employed as green manure, the crop being ploughed in. White mustard will produce 12 tons or more per acre on the richest soils. It is sown at the rate of 14 lb. per acre, the seed weighing 50 to 56 lb. per bushel, a pound containing over 70,000 seeds. *S. nigra* is grown for the production of mustard for the table.

Maize. (*Zea Mais.*) An annual cereal plant employed in many countries as green forage, and, especially in America, for conversion into ensilage for the winter feeding of cows. Maize grows luxuriantly in the warmer parts of England, while excellent crops have been grown as far north as Cheshire and Lincolnshire. It is a robust, tall plant, its height depending entirely upon the richness of the soil and the variety and quantity of seed used. It revels in hot weather, and during a warm, moist autumn evening it may be heard to grow—we refer to the popping of the immature leaves through the joints of the stem. Maize prefers medium deep soils, richly manured, especially with dung and phosphates. When broadcasted with 3 bushels of seed per acre, the plant grows thickly to a height of 3 to 4 ft.; when drilled or sown by hand in alternate furrows after the plough, 1½ bushels being used, the plants are much stouter, and will grow to a height of from 7 to 9 ft. The seed weighs about 60 lb. to the bushel, and will produce from 15 to 40 tons of fodder per acre. The lowest temperature of germination has been noted at 49° F. The table below illustrates the value of green maize as a stock food.

Among other feeding crops which are grown upon a small scale, but which are not regarded as farm crops are chicory, prickly comfrey—which is difficult to eradicate for a succeeding crop, and which, if abundant, is a poor forage—and the Jerusalem artichoke.

It may be pointed out with regard to all the plants which have been mentioned that while there is necessarily a limit to the weight of fodder which can be produced, the average crop grown in this and other countries is much smaller than is possible. Large increases are obtainable by high cultivation, and especially is this the case with lucerne, cabbage, rape, vetches, and maize. Given suitable soil and first-rate preparation, good seed and adequate manuring will be followed in four years out of five by very large additions to the crop

	Yield per acre fresh material.	Dry matter.	Dry matter per acre.	Digestible dry matter per acre.
	lb.	per cent.	lb.	lb.
Lucerne	35,000	25	8,750	5,162
Maize, whole plant	30,000	25	7,500	5,025
Red clover, about 3½ tons new hay	18,000	30	5,400	3,070
Oats and peas	20,000	16·2	3,240	2,106
Mangels	60,000	10	6,000	5,200
Potatoes	18,000	25	4,500	3,825

OTHER FARM CROPS

The Hop. The hop (Nat. ord., *Urticaceæ*; genus, *Humulus*) is produced from one species, *H. lupulus*. It is a perennial, diœcious plant—*i.e.*, the male and female flowers grow upon different plants, hence the importance of ensuring the plantation of a sufficient number of male plants. The hop prefers a rich, deep loam, well furnished with lime. The soil should be clean, thoroughly cultivated, both before and during the years of production, and heavily manured, not only with manure readily available, but with fertilisers, which gradually liberate plant food. The slow-acting manures employed include shoddy, rape dust, and horny matter. The hop is produced from cuttings which are planted on hills at equal distances apart. The cuttings—which are grown in different varieties—the cost of preparation, planting, poles, and string, along which the hop-bine twines, together with the picking and drying in the kiln, make this plant an expensive one to produce. As hop-growing is a somewhat risky industry, it is not surprising that it is costly in the market, and that growers are alternately elevated and depressed. An average crop is from 6 to 7 cwt., but the yield may be much more or much less. Hops are sold in "pockets," or sacks, of a given size, which contain 1½ cwt.

Flax. This plant (Nat. ord., *Lineæ*; genus, *Linum*) is grown in one species, *L. usitatissimum* [p. 881]. Flax prefers a rich soil with a fine deep tilth, and is not grown with success on clays or thin chalks and gravels. It is grown either for the seed or the fibre. The seed is chiefly produced for the oil, which forms more than one-third of its weight, the residue, after oil extraction, being pressed into cakes, which are used for cattle, and which contain 10 per cent. of oil. The straw, which is pulled before the plant seeds, is prepared, when fibre is required, by steeping. When grown for the seed or grain, 1½ to 2 bushels of seed are drilled per acre; when grown for the straw, 2½ bushels are drilled, the bushel weighing 52 to 56 lb., 1 lb. containing about 100,000 seeds. A ripened crop of linseed produces about 2 to 2½ quarters per acre, and from 35 to 40 cwt. of straw while the fibre produced varies from 5 to 8 cwt. per acre.

Hemp. The hemp grown in this country is of one species, *Cannabis sativa*, a diœcious plant; it thrives best on a rich, mellow soil of deep tilth, finely cultivated [p. 881]. The quantity of seed drilled is one bushel to the acre, a bushel weighing about 40 lb. It should contain about 30 per cent. of oil. The crop reaches some 2 quarters of 8 bushels, with 40 cwt. of straw; the weight of fibre varies from 6 to 8 cwt. per acre.

CULTIVATION OF FARM CROPS

It is the custom among farmers to grow the various crops on the arable land upon a system of rotation. It will be well to explain not only what that system is, but the principles upon which it is based. It is a commonly accepted maxim that it is bad farming to grow two white straw crops—by which we mean cereals—in succession on the same land. Highly skilled farmers, however, are able to grow these crops from year to year in absolute succession with most excellent results by maintaining the cleanliness and fertility of the soil. The rotation system, however, is to be preferred. It enables the farmer to produce greater variety of plants or crops, to maintain stock, such as cattle and sheep, and thus to produce abundance of farmyard manure, which is practically impossible where the land is employed, however skilfully, for the production of grain crops alone. The rotation system not only preserves, but promotes fertility. If a cereal crop is taken from year to year, it becomes necessary to provide manures containing nitrogen with great liberality, but although phosphatic manure is essential for some time, mineral fertilisers collect in the soil to a greater extent than they can be utilised for want of some other crop which would draw upon them.

Fertilisers for Cereals. Nitrogen is the dominant fertiliser of the cereals, phosphoric acid of turnips, and both phosphoric acid and potash of the pulses, clover, and other leguminous crops. If, therefore, we alternate these crops upon a recognised system, we enable one to feed upon the residue of fertility left in the soil by another, and in its turn to provide something for the crop which succeeds it. When a grain crop succeeds clover or beans, it is enabled to draw upon the store of nitrogen which these plants have extracted from the atmosphere and left in their roots. When the soil has been exhausted of available phosphoric acid and potash, it is once more supplied with these materials through the medium of such fallow crops as the turnip or the potato, both of which it is usual to manure with liberality, and, under good farming, with dung as well as artificial fertilisers.

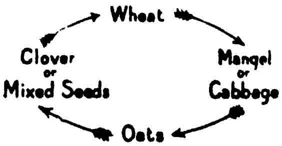
In a rotation a grain crop usually succeeds both the mangel and the potato, and is thus provided with what it requires, although in many cases it may still be advisable, where farming on the intense principle is followed, to give dressings of both phosphatic and nitrogenous manures. This is the more necessary for the reason that, under the four-course system of rotation, clover, or a mixture of one or more varieties of clover and rye grass, or of mixed grasses, is sown in spring with the growing cereal, to become in its turn a crop for feeding or mowing in the following year. The demand for food is therefore considerable, hence the importance of adequate preparation.

Value of Rotations. There are, however, other reasons why a system of rotation is advisable. By no other method is it possible to maintain the land in a clean condition—in a word, to destroy weeds. This cleaning is effected where plants, such as the mangel, the swede, the potato, the cabbage, kohl-rabi, or beans, are grown in rows sufficiently wide apart that the horse-hoe may be employed between them and the hand-hoe in the rows of plants themselves. Crops like the turnip or the cabbage, being frequently eaten off by sheep, indirectly improve the lighter soils, for the manure which is dropped adds fertility, while the compactness which follows the herding of the flock ensures a more perfect seed-bed. Again, the rotation system enables the farmer to keep within limits the ravages of insect and fungoid parasites, which are the cause of so much destruction. The crop being changed, the enemy, whose attacks are confined to a particular variety, practically finds its occupation gone; whereas if a crop which has been seriously attacked—as the turnip with the fly or with the fungoid disease known as anbury—were grown again upon the same field within one or two years, the probability is that the damage would be more serious.

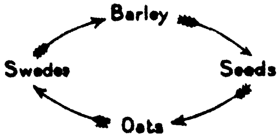
Prevention of Weeds. This question, however, like that referring to insect and other pests, will be dealt with in succeeding chapters. The better the cultivation, and the more liberal the manure, the fewer the weeds and the heavier the crops. Indeed, with heavy cropping, weeds have but little chance of arriving at maturity, while the material available for the production of dung becomes greater and greater in quantity. It is of prime importance, however, to prevent the seed of weeds, or even of cultivated plants, finding its way into the manure of stock, as, for example, the seeds of hay, which are so commonly found in the manure of the stable and the cow-house. Grass seeds conveyed to the soil with dung intended for feeding any other than a grass crop simply produces abundance of weeds, for grass is a weed in any but a grass field. For a similar reason, home-produced grass seed, as the sweepings of a loft, should not be employed on the farm owing to the fact that it contains weed seeds, which are only removable by the machinery of the seedsman.

The following diagram will suggest two methods of rotation:

HEAVY SOILS



MEDIUM SOILS



In that which is suitable to the heavier classes of soil, mangel or cabbage may follow wheat, and be succeeded by oats, or even by barley, where this plant can be grown with success. This corn crop may be followed by clover, or a mixture of clover and grasses, the seeds having been sown with the oat or barley crop, to be followed again by wheat, for which they have prepared the way.

Where it is inconvenient to take wheat—which is an autumn-sown crop, although under bad conditions sowing is sometimes delayed until nearly Christmas—oats may be taken, and where the necessary ploughing becomes impossible owing to bad weather, wheat sowing is abandoned, an oat crop is usually taken after ploughing the land later on.

Systems of Ploughing. The system of ploughing adopted by a farmer depends chiefly upon the soil, but largely upon custom. Deep ploughing should never be resorted to where the subsoil is brought to the surface. It is important, however, to plough as deeply as possible without harm in this direction for all fallow crops. Deep ploughing, too, makes the soil more porous, and paves the way for shallow ploughing in the case of most succeeding crops, which are in consequence more quickly started in life.

The dung produced upon the farm is usually employed for the wheat, mangel, and potato crops, but on many occasions land is also dunged for swedes, cabbage, rabi, and maize. The fertility of dung is not all utilised by the crop for which it is provided, a portion remaining for the benefit of succeeding crops.

In the rotation designed for the lighter soils, seeds are sown with the barley crop, which succeeds swedes which have been eaten off by sheep. The feeding of sheep on the land enriches the top three or four inches of soil, through which the roots of barley ramify in search of food. Assuming that the swedes have been grown by the aid of superphosphate, and that the sheep have also received cake, corn, and hay, it follows that the manure which they drop, both liquid and solid, not only contains a large proportion of the phosphates which were distributed on the soil for the benefit of the swedes, and which they have consequently taken up, but the fertilising constituents of the artificial food.

It is not surprising, therefore, that even poor, thin soils, such as those resting on gravel and chalk, are enabled to produce heavy crops of grain and straw, and to retain a sufficient residue of fertility for the benefit of the clover or mixed seeds which are cut in the succeeding year. In many large sheep-breeding districts these seeds, which may embrace sainfoin, sown alone, are, like the swedes, consumed by sheep receiving cake and corn, and thus the land is once more doubly enriched for the benefit of a succeeding oat crop, which many advanced farmers would assist with a dressing of such an artificial manure as sulphate of ammonia. This manure, on light soils, is preferred to nitrate of soda, owing to the fact that it is much less soluble, and, consequently, not so likely to be lost in the drainage water.

Four-course Rotation the Best. There are other rotations employed by farmers in various parts of Great Britain, but the four-course, or Norfolk rotation, to which we have specially referred, is the best foundation which can be laid. The greater, however, the grasp of principles, the better able is the farmer to form a rotation for himself, should he desire to make any change. Such a man will be able to take "catch" crops, to which we shall presently refer, and to supplant one crop for another, or even to allow his clover mixture or seeds to remain a second or even a third year before ploughing up for a succeeding grain crop.

ROME: GROWTH OF THE DEMOCRACY

Growing Power of the Plebeians. The Decemvirate. Frontal Wars. King Pyrrhus of Epirus and his Triumphs. Roman Colonisation. Carthage

By JUSTIN McCARTHY

THE cause of the Plebeians was gradually growing stronger. The renewed severity and energy of the attempts made to force the Plebeians into submission only proved that their opposition was at last becoming formidable, and gave them a fresh impulse towards organised and determined agitation. The result was that the Plebeians at last obtained better terms of citizenship, such as the right to sit and vote in the public legislative assemblies, on conditions approaching more nearly to equality between class and class. The public assemblies consisted of a Senate and a sort of representative chamber, both of which had been practically under the entire control of the Patrician order, until the agitation among the Plebeians and the coming up of the spirit of reform began to compel some constitutional changes.

Proposed Codification of Laws. Meantime, the Patricians had kept the whole legal system, such as it was, under their own control, and actually in their own hands. There was no written code of laws, nor was there any tribunal of appeal against a sentence passed by any existing court—unless, indeed, where a sentence of death had been passed, when an appeal was allowed to the general assembly of the Republic. The very existence of such an exceptional right of appeal is distinct evidence that Rome was already emerging from that condition in which absolute power can be held by any ruler or by any order. Terentilius, one of the Tribunes, brought forward a bold project of reform He proposed that a commission should be appointed to prepare a full code of laws for the government of the State—a codification of the laws at that time existing, and of the new laws which ought to be devised and brought into operation. The Patricians resisted the proposed change, and more than ten years passed before anything was done to bring about the reform.

The "Decemvirate." The interval was one of increasing organisation among the Plebeians, and at length it became clear that if the Patricians did not give way the result must be civil war. At last the Patricians yielded to the agitation, and ten men were chosen to prepare the new code. These men were called the Decemviri ("Ten men"), and to them was assigned, for a year, the whole government of Rome, during which time the new code was to be brought to completion. The laws which they prepared were finally accepted—willingly by the Plebeians and unwillingly by the Patricians. They were written on ten metallic tables and set up in the place where the legislative assembly used to hold its sittings.

During a second Decemvirate some other laws were added, and two more tables were accordingly set up. Five of the Decemviri were Plebeians and five were Patricians. When the Decemvirate had come into power it soon began to be seen that the Patrician and Plebeian members were alike unwilling to give up their official positions, and it appeared highly probable that this council of ten were determined to maintain their places, and to rule the State as a permanent authority, to the exclusion alike of the Consuls and the Tribunes, to whom for a long time both orders of the community had submitted. This apparent creation of a new despotic power began to be less satisfactory to the Plebeians than even to the Patricians.

Virginia and Appius Claudius. In the meantime, Rome had become engaged in a war against her Sabine and Volscian neighbours, and a great mass of the soldiers suddenly withdrew from the field of battle and assembled at a vast gathering—at what would now be called a monster meeting—in the centre of the city, and demanded the restoration to power of the popular Tribunes, who represented the interests of the people. To this period belongs the thrilling story of Virginia, which has been made popular by poets, romanceists, and dramatists in all languages of the civilised world down even to our days. The story is that one of the Decemvirs, Appius Claudius, who had been raised to his position because of his ability and public spirit, and who for a time continued to make himself popular, began at last to prove that he aimed at becoming an absolute despot. He was suddenly inspired with a passion for a beautiful Roman girl, Virginia, daughter of Lucius Virginius, a Plebeian who was serving in the Roman Army. Appius Claudius claimed a right to take possession of the girl on the ground that she was the daughter of one of his hereditary slaves This claim was resisted by the young woman's father; but a sort of sham trial, got up by Appius Claudius, gave as its judgment that she was actually a slave Then her father, to save her from dishonour, stabbed her to the heart in the presence of the crowd assembled to witness the trial

A Dramatic Ending. A feeling of horror went through the whole public at the conduct of the Decemviri, the Army rose in support of the girl's father, and the immediate result was that the Decemvirate was overthrown, and Appius Claudius sent to prison, where, it was said, he committed suicide to save himself from death on a public scaffold.

It is impossible to know with any certainty whether the whole story, or any part of it, is true;

but we must attach some importance to the fact that the story did at the time obtain general acceptance, and that the events it told coincided with the epoch when, for whatever reason, the power of the Decemvirate was brought to a sudden end. The result was that Rome returned to the system of Consuls and Tribunes, elected according to the former arrangements.

New Laws. Laws were passed to ensure the inviolability of the Plebeian as well as of the Patrician magistrates, to prohibit the creation of any magistrate from whom there could be no right of appeal, and to give an equal share in the making of laws to Plebeians and Patricians alike. Not many years passed before the development of reform made itself manifest in a new and striking manner. A law was made which allowed of marriage between Patricians and Plebeians, and thus struck at the very heart of the whole legalised Patrician system by sanctioning, and therefore encouraging, those intermarriages between the orders, and the bringing into the world of families descended both from the Plebeian and the Patrician class.

An important struggle took place as to the conditions of the consular office. No Plebeian could, up to this time, be elected a Consul, and for many years there had been a popular agitation for the removal of the restriction. A definite proposal to this effect was made by one of the most popular among the Tribunes, and it was opposed for a while with vehemence by the Patricians. The contest was destined to end as most of the struggles between the oligarchic and the popular order had hitherto ended. A compromise was suggested on the Patrician side, and many of the Patricians welcomed the suggestion in the absence of any better way for getting out of the difficulty.

A Compromise. The suggested compromise was that, instead of electing Consuls, the public should elect military Tribunes, who were at the same time to be endowed with the civic authority of Consuls. The reason given for this somewhat curious proposal was that Rome, being then engaged in a succession of frontier wars, needed more than two generals to command her forces. Even when this so-called compromise had been accepted and made legal, in 494 B.C., the Plebeians continued to gain in strength, and they were able to carry the election of these military Tribunes in the majority of instances. It is well to notice the fact that during all these various elections many of the same influences prevailed on both sides which were common to elections in much more modern times, and that bribery, intimidation, liberal promises, serious threats, and the secret purchase of votes during canvassing were freely exercised in order to obtain for the more powerful agitators, the majority of votes for their chosen candidates.

The Plebeians were becoming more expert in organisation, and at last became so successful that when the Consulships were restored, the Plebeians succeeded again and again in electing one of their own order to Consulship. The time soon came when all magisterial offices were thrown open to Plebeians and Patricians alike. The Patricians thus continued to lose privilege after privilege, and the Plebeians were beginning to be even richer as a class than those who had been their former rulers and masters.

In surveying this prolonged struggle, it will be seen that we cannot possibly regard the Patricians as a class animated merely by selfish motives and a desire to oppress their humbler fellow-citizens; nor can we look upon the Plebeians as entirely animated by an unselfish and patriotic love of liberty and equality. The whole struggle was in its nature and character very much the same as that which has gone on among all peoples rising into civilisation during the history of the world.

A Prolonged Struggle. The landed class has been brought up to believe its own order providentially endowed with the right to rule, and the lower classes have not unnaturally been inclined to regard themselves as the victims of selfish tyranny. In the nature of things the poorer classes grow, with the increasing opportunities which developing civilisation brings, into the capacity and opportunity for earning more money, for becoming traders and merchants instead of remaining mere tillers of the soil; they thus become the possessors of land for themselves, and are all the better able to hold their own against their social superiors.

This was, of course, a new story in Rome, but it has become a very old story in our days. The Roman Patricians and Plebeians were just what their early conditions made them, and either set of men put, in the beginning, in the place of the other would have acted, in all human probability, much the same part as that which was taken by the other.

For a long time after the creation of the Tribunes the same struggle went on between Patricians and Plebeians. The Plebeians were striving unceasingly for civic equality in politics and for a reform in the land tenure system, and the Patricians as obstinately fought against all such levelling projects. Many times there appeared in the Patrician ranks some man of more advanced views and more generous instincts than those of the majority of his fellows, who strove for agrarian reform and political equality. One of these enlightened reformers, Spurius Cassius, who had distinguished himself in his really patriotic efforts, was tried on some absurd charge of striving to make himself actual ruler of the State, was found guilty of the charge by a court under Patrician influence, and was put to death. His death, as often happens in the case of a patriot condemned for having striven in the cause of public reform, only served to call into existence other men inspired by his example and willing to risk much for the same cause.

The Old Story. Some of the Plebeians who had made money were drawn to side with the Patricians, in the hope, no doubt, of thus rising in the world. These men often lent their support to prevent their own order from succeeding in the effort after equality and land reform. The Plebeians, however, continued to win "all along the line." But in the meantime there were almost unceasing wars going on, and these wars tended inevitably to withdraw public attention from the struggle for domestic reform, and to make success in battle the great object and glory of the State. In all countries which are only as yet developing their civilisation, and have not permanently settled their form of government, such wars must naturally lead to the adoption for the time of some form of dictatorial power, and this tendency was already clearly manifesting itself in Rome.

Frontier Wars. The history of Rome had been almost from the founding of the city a history of continuous wars. The whole of Italy was divided into separate States, some of which were peopled largely by invading foreigners, and throughout the entire country there was no feeling of common nationality. When the Romans began to found a State of their own they had to accomplish their work to a great extent by intruding on the State of their neighbours; and when Rome had become thoroughly established and recognised as a Power, it stood out distinctly as an individual State in Italy; as France or Germany now does in Europe. There were frontier wars almost incessantly going on, begun by neighbours who desired to occupy some of the territory of Rome, or by Rome desiring to have and to hold some neighbouring land. The period following the rise of the Plebeians to political and civic emancipation and equality was made memorable by some of the greatest wars recorded in the history of Rome. It was beginning to obtain a complete supremacy in Southern Italy, where many Greek populations had long become established. This position, however, was not obtained until a most momentous and severe struggle had been brought to an end.

Pyrrhus, the Famous King of Epirus. One of the most famous sovereigns of those times—indeed, one of the famous sovereigns of the world—was Pyrrhus, King of Epirus, then, for the most part, an Asiatic realm. Pyrrhus had extended his dominions by his conquests in Western Macedonia, and in the year 280 before the Christian Era, the Tarentines—a Grecian colony in Southern Italy—implored his help against Roman invasion. Pyrrhus agreed to undertake the work of defence, and he sailed with a considerable army and a large number of elephants for the Italian shores. His first battle was long and fierce, and he lost in it a large number of his fighting men; but he won an unquestionable victory, mainly because of the presence of elephant allies—creatures such as the Romans had never seen before and against which they did not well know how to contend.

Pyrrhus seems to have well understood the nature of his victory, for tradition reports him to have said that after one other such victory he must have to return to Epirus alone. Some of the Italian States, who were growing jealous of the spreading power of Rome, became allies of Pyrrhus, and encouraged him in his northward march. He pressed on to within 20 miles of Rome, but there he found that the Roman preparations for defence were too strong for an attack with his remaining army. He fell back southward, and passed a winter in Tarentum, where he made his preparations for renewing the campaign.

Another Victory. He once more measured his strength with the Romans, and once again became victorious in the battle; but he was victorious at so heavy a cost that he found it necessary to withdraw for another interval to Tarentum and do his best to restore the strength of his force. A truce was agreed upon between Pyrrhus and the Romans, and Pyrrhus entered upon a new war-like enterprise. He went into Sicily to help the Sicilian Greeks against the Carthaginians, who were now becoming a formidable invading power endowed with a passion for conquest. Pyrrhus had much the same sort of fortune in Sicily as that which he had experienced in Italy. He began splendidly, but after a while received a severe repulse from the Carthaginians—a repulse which seems to have marred his calculations and dulled his hopes.

The Sicilian Greeks and he did not get on well together, and after a while he withdrew his forces from Sicily, with the object of again making war upon Rome. A serious mishap came upon him while he was crossing from Sicily to Italy. The Carthaginians attacked him with their navy and destroyed the greater number of his vessels. Pyrrhus was not a man to be discouraged even by heavy losses, and he went on with his attempts at the capture of Rome as if nothing had happened to diminish his military and naval strength. Again, the war god Mars, as would then have been believed, was against Pyrrhus. He sustained a heavy defeat at the hands of the Roman Consul, Curius Dentatus, and this ended his efforts to conquer Rome. He had to leave Italy and return to his own kingdom, Epirus, where he arrived with but a very small fraction of the army with which he had set out upon his expedition.

A Question of Supplies. Then a new difficulty presented itself. Pyrrhus was still the undisputed sovereign of Epirus, and still the commander of an army, but a perplexing question soon came up to trouble him—the question as to how he was to supply his army with food and clothing and weapons of war. His previous expeditions had already exhausted his resources, and there was not at that time, and in those regions, any loyal parliament to vote liberal supplies to the embarrassed ruler. No way of obtaining funds could suggest itself to the mind of Pyrrhus, except the undertaking of a new military enterprise which might end in the conquest of a foreign kingdom and the possession of ample spoils. He therefore undertook the invasion of Macedonia.

In this he was successful, and was created King of Macedonia. This was a position which he had already held as a youth during one of the conquests of Macedonia by the armies of Epirus, but his nominal rule over Macedonia only lasted for about half a year. Now that he was again King of Macedonia he led his armies against Sparta and Argos. His second rule as sovereign of Macedonia was not destined to last much longer than his first, for the Spartans defeated him in all his efforts to conquer them. True to the whole policy of his life, he immediately attempted an invasion of Argos, and there a fate befell him which we may believe would have been regarded by him as the most undesirable and the most unlikely close to his life of soldiering. He lost his life not on the battlefield, but by a stone or a tile thrown by the hand of a woman. The woman who brought to an end his varied military career saw him from her shelter on a housetop, and recognising him as the chief danger to her country, flung a heavy stone or tile at him, which struck him on the head and killed him.

Death of the Warrior Emperor. Pyrrhus was then in his forty-sixth year, and had reigned for some twenty-three years. According to all we learn of him from record and tradition, he was a good ruler over his own people, and over those whom he had conquered, except for his one ruling passion—the love of war and conquest. That one defect filled him with faults. During his few periods of peaceful rule he endeavoured to make his subjects happy, and he held advanced views of civil government and the equality of orders and classes. He was certainly one of the most brilliant soldiers of any time, and it was characteristic of him that no defeats or even successions of defeats ever brought to him a feeling of despair or shook his faith in his ultimate capacity to carry all before him. If soldiering could only be a religious faith, then Pyrrhus might be said to have lived and died in absolute devotion to his cause.

Roman Colonisation. After his death, Tarentum was handed over to the Romans, who levelled its fortifications and took possession of its fleet. Rome before long completed the conquest of all the Italian regions south of the Apennines and might now be regarded as the ruling power over the whole of Italy. It seems clear that the policy pursued by Rome was one aiming at the absorption of all the colonies which she had conquered into a willing submission to her rule and a desire for citizenship of the great rising State. Something like the sentiment of nationality was growing up throughout the Italian peninsula. "One Italy," the phrase so well known in our own times, had begun to be the motto and the prevailing desire of all the Italian populations which had been growing into self-ruling States. It is easy to understand how such a feeling must be stimulated in its growth by any attempt on the part of a foreign State to make herself the owner of Italian territory. Up to this time Rome had not made any effort to extend her dominion beyond the seas. She had not a great fleet, and was content with the construction of enough ships for the protection of her coasts.

Carthage. A new rival in power was coming into existence. In the recess of the Bay of Tunis, in the middle of the north coast of Africa, was the city of Carthage, which had been founded, as tradition tells us, by the Phœnicians of Tyre about a century before the building of Rome. The city itself is said to have covered an area of some fifteen miles in its most prosperous days. Poetic legend assigns the foundation of Carthage to Dido, the daughter of a Tyrian king—the Dido whose love for Æneas forms a thrilling episode in Virgil's great poem. Whatever may have been the origin of Carthage, it is certain that the city soon became the capital of a very powerful State. The Phœnicians had for centuries been a sea-faring race, and had established many ports and stations on all the seas within their reach. They were not warriors, but were animated by the spirit of travel and of commercial enterprise. They were by nature sailors and traders. They now proved themselves capable of brilliant war exploits as well; and, indeed, men who performed such daring explorations of seas hitherto unknown to them could hardly have wanted the courage which makes the soldier. Carthage soon became engaged in wars against some of her neighbours, and the result of these was that she found herself brought into rivalry with Rome. Rome felt an interest in some of the States against whom the Carthaginians made, or had to make, war, and the Romans set about the building of a fleet in order to enable them to contend against their maritime opponents. The Romans had the better in most of these encounters.

The Punic Wars. Then began those wars between Rome and Carthage which are known as the Punic Wars. A great soldier appeared among the Carthaginians, whose name will ever be renowned in the world's history. This soldier was Hannibal. He was the son of a famous Carthaginian general named Hamilcar, who had served with great distinction in the first Punic War. The story is told that while these wars were going on Hamilcar took his son Hannibal with him on one of his expeditions, and made him swear upon an altar eternal hostility to Rome. Hannibal was only eighteen years of age when his father fell in battle, and he seems to have kept ever in his mind the vow he had made of hostility to Rome.

He distinguished himself so much in the field that when he was only in his twenty-sixth year he was made Commander-in-Chief of all the Carthaginian forces. He is one of the first great military commanders known to history who succeeded in leading an army across the Alps in spite of the difficulties put in his way by the roadless mountains and their wastes of eternal snow. He marched directly towards Rome, and awaited the Roman army on the shore of Lake Trasimenus, a lake which the tourist can see from the windows of an Italian railway carriage. The Roman army was there completely defeated.

Continued from page 107

By W. E. GARRETT FISHER

IN the preceding sections we have dealt entirely with *descriptive geology*. We have considered the constitution of the rocks and minerals which form the crust of the earth. We now come in due order to the consideration of *physical*, or *dynamical, geology*. By this is meant the study of the various natural agencies which have given rise to the state of matters which now obtains on the earth's surface. It investigates the processes of change which are now at work upon the earth, and also helps us to see how, in the far-distant past, they have modified the primeval rocks. We have already seen that the earth's crust, when it first solidified from its original molten condition, must have been composed entirely of igneous, or crystalline, rocks. We know that at the present day the greater part of the surface is covered with soil and stratified rocks, which are very greatly changed from that earliest solid product of the fiery nebula. The business of physical geology is to tell us in what way these changes took place.

Uniformitarianism. The early geologists were in the habit of thinking that this beneficent change from the bare volcanic rocks and the fire-smitten deserts of the early world to the fertile fields which now grow ripe for harvest, and the kindly soil on which man lives and has his being, must have been due to some correspondingly extraordinary change in the order of Nature. They were always ready to evoke the aid of some gigantic cataclysm in order to explain the geological history of the earth. We are wiser nowadays, and find ourselves able to explain all these changes without going beyond the agencies which are still at work, both inside the crust of the earth and on its surface.

It is true that many of these agencies have been accustomed to operate in the past with far greater violence than they ever put forth in the present day. Our modern volcanic eruptions are trifling displays of fireworks when compared with the gigantic outflows of lava which produced many of the igneous rock formations of the earlier world. We know no such earthquakes as those which shattered and rent the crust of the earth while it was still thinly covering the subjacent abyss of liquid fire. Even the action of comparatively gentle agents like winds, rivers, and waterfalls is probably much slower nowadays than it was in the distant ages of the earth's history, as written in the fossiliferous rocks. The glaciers of the Alps and the Himalayas, even the gigantic ice barrier which defends the greater part of the Antarctic continent, are only a faint shadow of the ice sheet which once clothed almost the whole of Northern Europe. But though these agencies have lessened in degree, they are still the same in kind. The great doctrine of *uniformitarianism*, which was enforced by Sir Charles Lyell with all the weight of his genius, and is now universally accepted by geologists, teaches us that we need not attempt to explain the history of the earth by introducing any agents which show a marked difference from those which are at work to-day. Such convulsions of its surface as the earth has known still find their analogues in the processes of Nature, and were at the utmost only an exaggeration of the processes which we can watch in action at the present day.

Processes of Change. We all have a general idea of the *processes of change* which are now at work upon the rocks. We see the wind day after day sweeping up the dust from one part of the dry earth and heaping it up in another. We know that when the rain falls it converts this dust into mud, and often washes it away, leaving the surface of the fields or roads bare sheets of naked rock. The farmer and the gardener tell us how frost pulverises the soil and splits up stones and rocks. We cannot take a country walk without seeing how the little streams and rivers are continually washing soil away from one place and depositing it in another. An inexpensive excursion to Switzerland will familiarise us with the work of glaciers in chiselling out valleys, smoothing rock-surfaces like gigantic planes, and transporting vast boulders from their perches high up among the hills to perplex travellers in the valleys. Every holiday at the seaside shows us how the waves of the ocean are continually battering the shore, breaking down the hardest quartz rock into fine sand, and ever making deeper and deeper inroads upon the most lofty and imposing cliffs.

Internal Influences. We are less familiar with those agencies of change which are within the surface of the earth. In this part of the world, at any rate, we have no acquaintance with volcanic activity; and if an earthquake does come our way, it is so gentle that, as a rule, we only learn of its existence from the newspapers next morning. But we know from the reports of travellers in the tropics that volcanoes are still at work pouring out lava over the surrounding land, that earthquakes are still competent to swallow up whole villages, and open chasms, which seriously affect the surrounding strata. It is our business now to study the action of these various agencies as modifying the crust of the earth.

Hypogene and Epigene Agencies. We may divide these agencies into two classes for convenience of study, according as they operate above or beneath the surface of the earth. There is a fairly obvious distinction between the superficial agents which produce such changes as we mean when we speak of the weathering of rocks, and those subterranean forces which are the cause of volcanic activity, and give rise to earthquakes or to less perceptible secular movements of the earth. The subterranean agencies are called by geologists *hypogene*, while the superficial are known as *epigene*. Both these agencies, which do so much work upon the earth's crust, owe their existence to the same source of energy, being derived ultimately from the heat of the original nebula out of which the whole solar system has been developed. [See ASTRONOMY.]

The hypogene agencies, as may be readily seen, are mostly due to the heat still remaining in the interior of the earth. It is no difficult task to trace the association of volcanoes with the central fire, and we shall see later that earthquakes, and the slow secular movements of the earth's crust, are alike due to the fact that the earth has been slowly cooling since it first came into existence.

The epigene agencies owe their powers almost entirely to the heat of the sun, which is itself the residue of the original nebula. They are practically all due to movements of air and water, or to changes of the temperature, or to the action of life; and none of these could exist if it were not for the sun's heat.

Agencies of Change in the Earth's Crust. It will be convenient here to notice the various agencies of terrestrial change in tabular form before we go on to deal with them in detail.

1. HYPOGENE.
   (*a*) Volcanoes.
   (*b*) Earthquakes.
   (*c*) Slow secular movements.
   (*d*) Chemical action.
2. EPIGENE.
   (*a*) Atmospheric.
   (*b*) Aqueous.
   (*c*) Glacial.
   (*d*) Organic.

37. EXTINCT VOLCANOES IN THE MOON

HYPOGENE AGENCIES

Volcanic Action. By a volcano we usually understand a mountain, generally of conical shape, whose summit contains a crater, or opening, through which hot vapours, hot gases, volcanic bombs, ashes, and streams of molten lava are ejected during its activity. Vesuvius, Etna, Krakatoa, and Mont Pelée present familiar types of such mountains. All volcanoes, of whatever type, are simply channels of communication between the surface of the earth and the reservoir of molten rock which exists at a varying depth in the interior of the crust. In the past, however, volcanic activity has by no means been always associated with mountains of this kind. When the earth was younger, and the solid crust was considerably thinner than it is nowadays, there were vast eruptions which were due to the rending of the crust along huge fissures, often hundreds of miles in extent, from which millions of tons of molten igneous rocks welled out and submerged the surrounding country. The only recorded example of such a *fissure eruption* in modern times is that which took place in Iceland in 1783; but the study of the geological record shows that such phenomena were extremely frequent in earlier ages, and gave rise to vast masses of igneous rock.

A Simple Volcano. It is easy to see why the modern volcano is almost invariably a conical hill or mountain. If we consider what happens at a vent which has thus been opened between the molten interior and the surface of the earth, we shall see that the molten rock, welling up from within the crust and overflowing in all directions from the vent, rapidly solidifies into a roughly circular mass, of which the vent is the centre. When more molten lava is poured forth, it still wells out in the same circular form, and the cone is gradually built up round the vent, which is bored through it as a vertical pipe. The simplest type of volcano is that of a single cone thus formed around one centre of eruption. The summit is usually truncated, and presents a cup-shaped cavity, called the *crater*, into which the central pipe opens. Most existing volcanoes consist of not one, but many cones, each of which has at times been a centre of eruption. This considerably complicates the original constitution shown in the diagram [36]. A very fine instance is presented by Mount Etna, where there are at least two hundred of such cones.

Volcanic Products. The volcanic vents which connect the surface of the earth with the molten interior emit various kinds of material, which may be classified as gases, water-vapour, lava, and rock fragments or dust. Many of the *gases* emitted by volcanoes have a corrosive or solvent action upon the rocks with which they come in contact. Superheated steam, which is one of the gases most common among volcanic products, has a powerful disintegrating action upon the lava through which it breaks its way. The water which many volcanoes emit—generally, of course, in a highly heated condition—collects large quantities of volcanic dust, and forms a pasty conglomeration of what is known as mud-lava. The chief importance of volcanoes, however, as agents of geological change consists in the *lava* which they emit. Lava is a term generally applied to all the molten rocks which are ejected from the interior of the earth. We have seen in the preceding chapters that a large proportion of the igneous rocks which originally formed the whole of the earth's crust were once volcanic lavas. They vary considerably in chemical composition, in structure, and in texture; but a larger text-book must be consulted for details. Lastly, in addition to gases and molten lavas, solid fragments of rocks are frequently ejected from an active volcano. The larger of these are known as *volcanic bombs* or *blocks*, which are simply pieces broken off from already solidified columns of lava, and hurled out of the vent by the pressure of gas, just as a shell is fired from a cannon. A great quantity of solid matter is also ejected from volcanoes in the form of *dust* which has been produced by the disruptive effect of gases at a high temperature and under great pressure. They explode, so to speak, as the lava with which they are mingled approaches the surface. This dust is often sent floating up high into the air and is diffused by the atmospheric currents over a very large area. It has sometimes been known to travel half round the world before subsiding to the earth. The great eruption at Krakatoa, in 1883, is believed to have caused in this way the remarkable sunsets which were seen in England during the following summer.

Volcanic Action Everywhere. There is practically no part of the world, as we now know it, in which traces of volcanic action cannot be found. Once upon a time the earth seems indeed, to have been split and furrowed in all directions by the activity of the central fires which are now approaching a state of quiescence. Nowadays volcanic activity is limited to a comparatively small number of regions, and extinct volcanoes are considerably commoner than active ones. Arthur's Seat and North Berwick Law, in the Scottish Lowlands, the regions of the Auvergne in Central France, and the volcanic Eifel, beside the valley of the Rhine, offer good examples of volcanoes once active, but which have shown no signs of eruption for thousands of years. There is no essential distinction between extinct volcanoes and dormant volcanoes, as history shows that a volcano which has been extinct so long as human memory records may suddenly break out into a remarkable state of activity. This was the case *with Vesuvius just before the destruction of Pompeii. But there can be no doubt that, on the* whole, volcanic activity has steadily declined since the beginning of human history, and that a time will come when all our terrestrial volcanoes will be as inert as those of the moon [37].

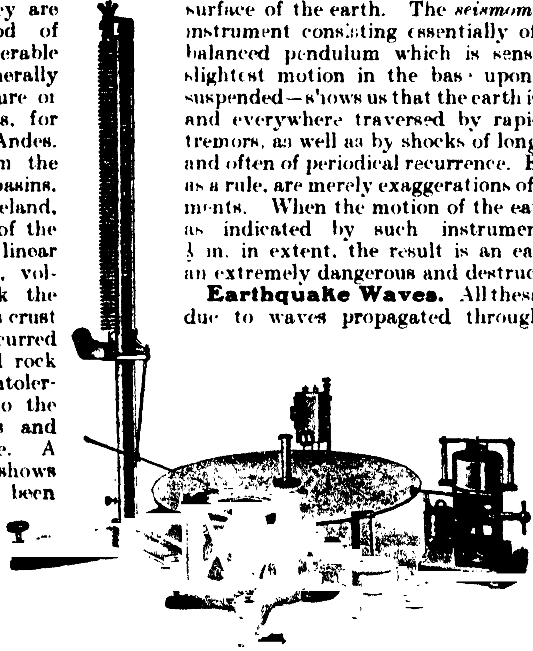
Distribution of Volcanoes. The distribution of active volcanoes, of which there are between three and four hundred now in existence, deserves study. They are found in greatest number on the shores of the Pacific Ocean, where more than half of the now active volcanoes are situated. As a rule, they are situated in the neighbourhood of the sea or of some considerable sheet of water. They are generally arranged along lines of fracture or folding in the earth's crust, as, for instance, in the chain of the Andes. Many volcanoes also arise from the submarine ridges of the ocean basins, and a few, as in Italy and Iceland, are ranged in groups in place of the prevailing distribution in a linear series. Geologically considered, volcanoes may be said to mark the places of weakness in the earth's crust where some vast fracture has occurred in the rocky mass. The liquid rock of the molten interior, under intolerable pressure, makes its way to the surface through these fractures and along the lines of least resistance. A study of the geological record shows that volcanic action has always been most abundant in certain limited areas which mark these great lines of weakness in the earth's crust. The special geological work of volcanoes and of fissure eruptions has been to bring to the surface the vast masses of igneous rock which in many cases have thus been intruded among the strata of earlier sedimentary rocks, upon which they have had a well-marked baking or metamorphic action

Geysers. In speaking of volcanic action one should mention the curious natural fountains known as *geysers* [38], so common in Iceland and in the Yellowstone Park. Those are, so to speak, water volcanoes, or springs, which rise from an extremely hot region. Their water is periodically ejected in jets or fountains by the pressure of steam formed in the lower portion of the pipe and unable to escape except by this explosive action.

Earthquakes. The study of earthquakes, known as *seismology*, has made a very considerable advance of recent years. This is largely due to the interest that Japan, as a rising nation, has been forced to take in the convulsions which are continually shaking her cities to the ground, and which compel her architects to study the conditions necessary for erecting permanent buildings, in spite of these constantly recurring and inevitable shocks. Earthquakes in our own country, as we know, are scarcely ever violent enough to endanger our buildings; at the worst a wall may be cracked, or a chimney shaken. But in the countries where earthquakes are frequent and considerable in extent they have been known to cause terrible destruction. The city of Caracas was nearly destroyed in half a minute, with 10,000 of its inhabitants. Port Royal, in 1692, and Lisbon, in 1755, were almost entirely wrecked by earthquakes.

We know now that these gigantic convulsions are merely the temporary exaggerations of tremors which are constantly passing through the surface of the earth. The *seismometer* [39]—an instrument consisting essentially of a carefully balanced pendulum which is sensitive to the slightest motion in the base upon which it is suspended—shows us that the earth is continually and everywhere traversed by rapid and weak tremors, as well as by shocks of longer duration, and often of periodical recurrence. Earthquakes, as a rule, are merely exaggerations of these movements. When the motion of the earth's surface as indicated by such instruments exceeds ⅛ in. in extent, the result is an earthquake of an extremely dangerous and destructive kind.

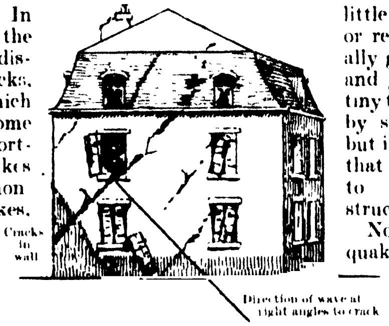
Earthquake Waves. All these tremors are due to waves propagated through the crust of the earth by causes analogous to the explosion of a mine or the fall of a huge stone. The jar which we feel throughout the house when a heavy vehicle passes along the road, or when a stout man jumps out of bed on the upper floor, is precisely similar to what we call an earthquake, though, fortunately, less in degree. These earth-waves travel at definite speeds, which can be measured with considerable accuracy and which vary according to the substance through which the waves are transmitted. They naturally travel faster through a hard and close-grained rock like granite than through a loose substance like sand. The direction in which they are travelling at any particular place can be determined by observing the direction in which walls [40] or similar objects are cracked by shock, and which are, of course, at right angles to the emerging wave. If, when an earthquake



39. SEISMOMETER

occurs, several observations of this nature have been made in different places, it is possible to make a fairly close approximation to the place at which the earthquake originated beneath the surface by prolonging lines backward from each of these stations, and calculating the point at which they would all meet within the earth [41]. It has thus been observed that earthquakes usually originate within the upper portions of the earth's crust at a depth which is seldom greater than 14 or 15 miles.

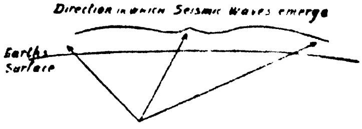
The Cause of Earthquakes. It is not difficult to see that we must look for the cause of all earthquakes, from the merest tremors insensible to man (which nevertheless leave their traces on the delicate instruments of the seismologist) to the vast cataclysms which wreck whole cities and submerge long coast-lines beneath gigantic ocean waves, in some subterranean shock or displacement. This may occur in various ways; sometimes it may be due to the sudden collapse of the roof of a subterranean cavern. In limestone districts, where the underground water is able to dissolve the substance of the rocks, and thus to leave huge caves, which every now and then become incapable of the task of supporting their roofs, small earthquakes of this nature are not uncommon. A small number of earthquakes, again, are no doubt due to volcanic explosions in the lower regions of the earth's crust. It was once supposed that earthquakes were always closely connected with volcanoes, but this proved to be an erroneous view; and, as a matter of fact, the most powerful and numerous earthquakes occur outside the limits of volcanic districts.



Cracks in wall
Earth's Surface
Direction of wave at right angles to crack

40. HOUSE SHAKEN BY EARTHQUAKE

It is now generally admitted that the recognised cause of most earthquakes is to be found in the sudden yielding of subterranean rocks which are under great strain from the superincumbent strata. It can readily be seen that at a depth of five to fifteen miles beneath the surface, where the majority of great earthquakes originate, the rocks must be in a state of extreme **strain. Every mile of the superincumbent strata is probably responsible for a pressure of 20 or 30 tons to the square inch upon those which lie beneath, and it is clearly conceivable that** every now and then the most massive rocks must yield or snap under this intolerable pressure. When they do so, a more or less violent set of waves are originated, which radiate outwards in all directions, and when they reach the surface of the earth give rise to all the destructive phenomena which we call by the name of an earthquake. There can be little doubt that these ruptures, or readjustments, are continually going on in a small way, and give birth to the constant tiny tremors which are recorded by seismological instruments; but it is comparatively seldom that they are violent enough to produce seriously destructive effects.



41. DIRECTION OF EARTHQUAKE WAVES

Not infrequently earthquakes take place on the floor of ocean basins, where they generally make themselves known by the propagation of vast ocean waves, which cause serious, and often fatal, inundations when they reach the nearest land. In 1896, nearly 30,000 people were thus drowned on the coast of Japan by an earthquake wave, which was also felt at San Francisco, nearly 5,000 miles away. Submarine telegraph cables are not infrequently broken by these submarine earthquakes, and a famous scare of invasion was raised in Australia a few years ago by the simultaneous destruction of all the cables, and the consequent isolation of that continent from the rest of the world.

Continued from page 1069

THE PIANOFORTE

Meaning of Technique. The Instrument. The Two-fold Function of the Keys. Control of the Key Hammer. Keyboard and Pedals. Correct Position of the Hands

By M. KENNEDY-FRASER

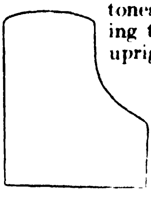
WE have already studied the Theory of Music, the nature of Scales, the laws of Tonality and the nature and function of Rhythm, etc. We have learned how music is written down, how to read its notation. We have now to learn to reproduce written music—to "make music," as the Germans say—and to do this by means of the pianoforte.

Our pianoforte education has two distinct branches. In the one we learn to conceive the effect intended by written music. We learn to hear it with the mind's ear, we learn to think it. In the other we learn to express this thought by sounds that we and our audience can hear. This latter branch we call *technique*, in the fullest sense of the term.

Technique. The learning of Technique (the power of expressing ourselves) used to depend on an aptness for imitation. Our teachers played, and we did our best to imitate them ; and, by dint of much trying, sometimes succeeded. They could teach us these matters of execution by example and suggestion only. But now both the how and the why of good piano technique have been discovered and written down for us, so that it is possible for all of us to learn from books. These books are "The Act of Touch," a scientific treatise, and "First Principles of Pianoforte Playing," a student's primer, both by Tobias Matthay. They show how it is possible to acquire (in a direct way) all the different forms of expertness included in the term Pianoforte Technique. For the term thus used in its widest sense simply means the ability to use the keys effectively and easily, and, as Mr. Matthay has said, "on our correctness in the Act of Touch, therefore, depends all success in pianoforte playing in whatever direction, agility, beauty of tone, brilliancy, power, and ability to give those inflections of tone from note to note which render music intelligible." Our entire technique depends, therefore, on our obedience to these Laws of Touch, and on our technique again depends entirely our power of expressing what we feel

To begin the study of pianoforte playing in this direct and scientific way which has thus been made possible for us, we must, before thinking of our fingers and hands, find out what the piano is, and what treatment it requires from us.

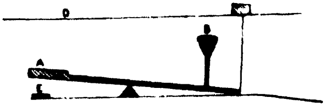
Instrumental Facts. The pianoforte is a harp-like instrument enclosed in a wooden box, the nature of which is disclosed by the "case" of a "grand" piano, which still retains this harp-like shape, although now supported table-wise on three legs. The upright or "cottage" piano, although its case is quite different in shape, is still harp-like within. The strong metal frame [1] strung with wires, from the short, thin ones giving the highest tones to the stout long ones sounding the bass, is thus no longer held upright by the player like a harp, nor are its strings plucked by his fingers. But, instead, carefully poised *hammers*, covered with thick felt, are driven against the strings to set them in vibration. These hammers are controlled by a set of cunningly devised wooden tools, overlaid with ivory or ebony at one end—the end that presents itself to the player's fingers.



1 FRAME

The instrument consists of two distinct portions : (1) the music-making portion—*i.e.*, the strings and their reinforcing sounding-board—and (2) the set of tools wherewith we may induce the sound.

Function of the Keys. Now, these "tools" have a two-fold function. They are see-saws, offering an ivory or ebony *key* to the finger at one end, and furnished with a hammer to strike the strings at the other end ; and these "keys"—note this—control the actions, not only of the hammer with which we excite tone at will, but also of the "damper" with which we stop off tone at will. Thus the keys are the tools with which we chiefly command the vibratory—*i.e.*, sound-producing powers of the instrument, and we must examine them closely. The key is a lever, of the nature of a see-saw, and its position and action are roughly shown in Fig. 2.



2. THE KEYS

A. Ivory Key-end. B. Hammer. C Damper. D. String. E. Key-bed felt

Control of the Key Hammer. Let us press gently on the ivory end of one of the keys of the piano. It will go down under the pressure (as would a see-saw), and, the other end rising, will, if the action be swift enough, throw the hammer against the strings. The strings vibrate and produce a sound. Now release the key from the weight of the hand and arm ; the key will rise, and, as it rises, the sound will cease. What has happened ? When, by the see-saw motion of this key-end, we managed to throw the hammer at the other end against the string, did the hammer, after hitting the string, continue to press against it ? No. For, if it had done so, the string would not have been free to vibrate, and no tone would have resulted. What happened was this: the hammer, as soon as the sound was produced, fell back a little way from the string and allowed it to vibrate freely; and this the string continued to do till we suddenly released the key, and the tone as suddenly ceased.

The Damper. Why did this happen, and why must we keep the key depressed if we wish the sound to continue? Because the key, when depressed, is keeping the damper off the strings, and when the key is allowed to rise the damper is permitted to settle down again on the strings and stop their vibration. Remember, then, that when a key is moved it is the *beginning* of the sound which indicates that its hammer function has been fulfilled—all that remains, the continuance of the sound, depends on its damper function. And this is the first thing we must learn, and the last thing we may forget in using piano-keys to make music.

The Key-bed. We know something about the key with its hammer and its damper attendants, but in the key's retinue there is another small unseen, and at times ill-treated, appanage that concerns us as pianists, and must not be overlooked. This is the little piece of felt under the extreme finger-end of the key, which prevents the key from jarring against its wooden "bed" when it is pushed down. The see-saw key manages to throw the hammer against the string just before it (the key) reaches the bottom of its "bed," and if we were keen enough always to listen for the beginning of the sound and never to move the key any further than to that moment of sound-birth, these poor down-trodden key-bed cushions would be unnecessary. But careless, unskilful players, and even adepts at times, try to drive the keys too far down, and these "felts" in the bottom of the key-bed act like buffers and soften a probable, but quite uncalled-for, collision which might otherwise prove disastrous to the pianoforte mechanism. They may thus be used, but should never be abused, and, to quote Mr. Matthay, "should certainly not be squeezed 'as though they were ripe fruit from which we could extract sound-juice.'"

The Keyboard. The finger ends of the keys are not all alike. They are grouped in easily recognisable patterns in black and white. The even row of ivory—in full "grands" 52—is backed and intersected by a higher and narrower row of ebony keys (36), and these fall into alternate groups of twos and threes. The entire series (88) is called the keyboard, and the player is expected to reach and control with one or the other hand each key in this "manual" [3].

3. KEYBOARD

Damper Pedal. But in addition to the keyboard, or manual, we shall find two pedals to be worked by the feet. The right-foot pedal controls the dampers. Depressing it, we raise all the dampers simultaneously off the strings. With the damper pedal thus depressed, a tone produced by the down movement of a key will continue to sound even after the key has been allowed to rise. But this damper pedal not only prolongs the sound, even should the key rise—it affects also the *character* of the sound. For, all the strings of the instrument being by its action left free to vibrate, many of them vibrate in *sympathy* with the hammer-affected strings, adding thus to their original volume of sound, while by the non-percussive quality of their tone they affect also—and this is important—*its quality*. This right-foot pedal is often termed the "loud" pedal. It may be used while playing at one's softest, but its application will be treated further on.

The "Una Corda" Pedal. The other pedal is controlled by the left foot, and its function also is one of affecting the tone quality of the instrument. To explain its use we must again examine the harp-like arrangement of the strings. The long, thick bass strings are single—one to each hammer and key—but, as with the rising pitch the strings get shorter and thinner and consequently weaker in tone, we have two strings tuned to one pitch, and, higher up, three. The left-foot pedal when pushed down in a "grand," moves the whole keyboard with all its hammer mechanism a little to one side, so that a hammer no longer strikes all the strings allotted to it, but leaves one unstruck, and this one, sounding with a *sympathetic* vibration only, modifies the character of the tone.

That the part of the hammer which comes now in contact with the strings is less used, and consequently softer, will also slightly affect the tone. The left-foot pedal is often erroneously called the "soft" pedal. It certainly does weaken the tone-amount, but we may play at our softest without it. It is properly termed the "una corda"—*i.e.*, one-string pedal. The early piano did not have more than *two* strings, and the "verschiebung"—to use the German term for the "una corda," meaning the pushing aside—permitted the hammers to strike only *one string*. The damper and "una corda" pedals may be used together. Care should be taken when using the "una corda" pedal to *fully* depress it, provided it is properly adjusted.

How the Keys are Named. Most "uprights" are without this device, and are provided instead with a strip of felt to soften the tone, or other devices, none of which, however, takes the place of the proper "una corda."

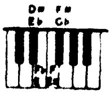
Roughly speaking, the earlier music, even up to the eighteenth century—*i.e.*, before Beethoven's time, may be and often *must* be played *without* the use of either pedal, while most of the pianoforte music of the nineteenth century—that of Chopin and Schumann, for instance—cannot be adequately performed without the use of one or both.

Now let us return to the keyboard, for it is with the keyboard that we shall have to occupy ourselves chiefly; *but* let us never forget—as pianists are only too apt to forget—that the keyboard is *not* the instrument, but merely the "set of tools" with which we may use it. We must learn, then, to be expert with these tools, so let us make their better acquaintance. Seated at the middle of the keyboard, let us pass our hands over it. It presents an uneven surface to the touch, the ebony keys lying higher than the ivories. This uneven surface is an advantage.

We must learn to read easily the music written to include the black keys, since it is easier to *play*, though more difficult at first to *read*, than music employing only or mostly the white keys.

What, tonally, does this keyboard command? A series of sounds, each half a tone apart. And its 88 keys are named with but seven letters of the alphabet—from A to G. The white keys only are named; the ebonies take their names from the ivories that lie next to them. This series of seven letters repeats itself throughout the extent of the keyboard; that from A to G was the old form of our modern minor scale, that from C to B the prototype of the modern major scale.

Eye Knowledge of the Keyboard. We must learn to recognise quickly and surely the place and letter name of each white key by its place in the *keyboard pattern*, by its relation to the groups of two and three black keys. Take D first, between *two* blacks, and find D's all over the keyboard; listen to them—all alike though different. Next find C's and E's, next-door neighbours to D's; add B's and F's, each at the extremes of the three black-key groups; and finally add A and G. We must work at this (with other studies) for days or weeks till mastered. Later, add knowledge of altered notes, notes raised or lowered half or whole tone. For such sharpened (raised) or flattened (lowered) sounds we must use the contiguous black or white keys [4]. But finding the keys by the eye, and testing their pitch, and trying to remember this by ear (as the musician must do), is, after all, only the beginning of knowledge for the pianist. *He* must learn to find and recognise the keys *blind*. This he can do only by the sense of touch and by mental muscular measurements. Again, to do this, he must learn with his fingers and hands to *rest on the keys*.



4. RAISED AND LOWERED NOTES

If we have studied carefully every word of what has been said we now know something of the instrument, and of the mechanical means provided in it for producing tone.

Importance of Resting. The next question is, how must we *use* the keys? How direct the arm, hand, and finger against the keys to move them? We must learn, first, to *rest* on them, that our sense of touch may tell us where they are, and that another sense—"the muscular sense"—to which we must pay great heed, may tell us how heavy they are, *how much resistance* they offer to our resting weight. In order that the fingers may really *rest* on the keys, the hand must be allowed to hang loosely—limply—from the arm. We must learn this first.

In the daily active use of the fingers (apart altogether from piano playing or study) the hand never hangs from the arms; yet in active finger piano playing it must learn to do so. This is a muscular condition which, in active use of the fingers, is quite new to us. We must study it, understand it, and be able to induce it with perfect ease, and never rest satisfied without daily testing it at the keyboard and away from it.

5. LOOSELY HANGING HAND

Position of the Hand. To learn what we mean by hanging the hand loosely on keys, let us try holding the hand *over* the keys, but not touching them, in the way indicated in 6

It is evident that *as long as we do not touch the keys* the hand (at this angle to the arm) is supporting itself; it is *not* hanging loosely from the arm; we are using its upholding muscles, the muscles that prevent the hand falling by its own weight. These must relax; they must relax so that the hand in playing may be supported on the keys by the fingers. The appearance, the mere *position* of the hand when the fingers are on the keys, will not help us in securing the loose wrist; for the wrist may be held high, medium, or low, and in any of these various positions may, or may not, be stiff. If we would make sure of the loose wrist we must see to it that the hand is really *suspended* between arm and fingers, and that being the case it will hang loosely whether the wrist-end of the fore-arm be held high or low.

MUNICIPAL CLERKSHIPS

Appointments under a Typical Council. Junior Clerks and their Prospects. Draughtsmen. Clerkships. Women Typists

By ERNEST A. CARR

THE incomes of municipal clerks vary almost indefinitely, according to the duties they perform and the liberality or otherwise of their employers. At the head of the calling are such responsible positions as principal clerkships under the City Corporation, with salaries ranging between £650 and £1,000 a year. The other extremity is occupied by temporary office clerks, performing routine duties for a bare £1 a week. Between these extremes lies every imaginable gradation in value and dignity; and as there is no uniformity of system in the Service, each local authority being a law unto itself, the vast bulk of clerical employment is too incongruous to admit of precise classification. To this general want of system, however, there are many exceptions, the most notable case being that of the London County Council, whose clerical staff will be separately considered in the course of this article. It is necessary also to remember that for some officials municipal clerkships are merely stages on the road to leading or professional rank, whilst for others they are both means and end.

An Expert's Views. The courtesy of the Town-clerk of Birmingham enables us to present to our readers an admirably clear and comprehensive summary of the general prospects afforded by clerical employment in a corporation of average size. After premising that special factors may influence the progress of every clerical staff, Mr. Edward O. Smith, the Town-clerk referred to, proceeds as follows.

"Generally it is the practice for corporation clerks to start as juniors or office boys at salaries ranging from £15 to £25 a year, the necessary qualifications being, as a rule, that the lad is of good character, has had a fair education, and (in most cases) shows a good knowledge of figures. Junior appointments are sometimes filled on the recommendation of head masters of public schools who have likely pupils leaving school and desirous of getting into the Municipal Service.

"In the large departments of the Corporation, such as gas, water, electric lighting, or public works, these juniors would progress into counter, rental and exchange clerks, accountant and ledger clerks, cashiers, collectors, and district clerks, with maxima of about £150 to £180 a year. The work of these clerks is in most cases routine, but exceptional ability may be rewarded with positions as chief clerk, office superintendent, departmental accountant, etc., with salaries ranging from about £250 to £500.

"In the Treasurer's Department the same rule as to juniors may be said to exist. Here a good knowledge of figures and some bookkeeping skill are special qualifications. Appointments as cashiers and ledger clerks are usually recruited from the junior staff, and salaries range from £80 to £250 a year. In this department, also, there are higher appointments, as chief bookkeeper, chief accountant, and other posts, with salaries running up to about £500 a year.

"With regard to the Town-clerk's Department, a rather higher standard of education is required here than is the case with the other departments of the corporation. Appointments of committee clerks are usually held by the town-clerk's staff, with salaries ranging from about £200 to £300 a year. In this department are law clerks and parliamentary, registration, and election clerks, with salaries ranging from about £100 to £350 a year. In nearly all cases these appointments are filled by clerks who have gradually progressed to their position by long service and experience."

Junior Clerkships. The broad plan thus ably sketched is subject in particular instances (as its writer expressly concedes) to many modifications. A number of borough councils, for example, prefer to recruit their clerical staff by taking into their service, at more substantial salaries, youths between the ages of 17 or 18 and 21 years who have already had some special training for office life. In such cases a knowledge of shorthand and typewriting, or experience in a commercial office, is usually essential; and the remuneration, starting at some figure between £45 and £70 a year, advances annually £5 or more to a maximum of £80, £100, or £120. Promotion to higher posts, while always based upon ability and merit, is in some municipal offices dependent on the occurrence of suitable vacancies. Other authorities graduate their staff in three or four classes, providing that when an officer attains the maximum of his class his claims to promotion to the next may be considered irrespectively of office vacancies.

How to Enter. It may be useful at this stage to consider definitely what steps should be taken by a lad (or by his parents on his behalf) for whom a municipal clerkship is desired. In the first place, he should be trained to write a good clerkly hand, rapid if possible, but, at all costs, distinctly legible. Commercial arithmetic, and especially the ability to manipulate large masses of figures without a mistake, is more valuable to him than uncertain flights in higher mathematics. It follows from what has been said about the qualifications of junior clerks that a knowledge of shorthand and typewriting and the rudiments of bookkeeping are also very serviceable acquisitions.

As soon as the aspirant is moderately adept in these studies, which should be in or about his sixteenth year, the town-clerks of several suitable corporations should be approached. The larger the boroughs, of course, the better are the prospects of a vacancy. From the head official, particulars can be obtained as to the qualifications required of candidates, the age limits imposed, and the method by which vacancies are filled. If the prevalent practice is followed of maintaining a "waiting list" of suitable candidates, all that remains is to comply with whatever formalities are requisite for the insertion of the student's name, and to continue his training while awaiting notice of a vacancy. It may be, however, that the lists are already overburdened with prior claims, or that appointments are advertised—though this latter method is not generally adopted in respect of office youths and junior clerks. Recourse should then be had to other authorities; and meantime the announcements of municipal vacancies referred to in a previous article (page 451) should be scanned, and application made for such junior positions as are advertised, until, by either method, a suitable post is secured and the youth is launched on his official career.

Prizes of the Clerical Service. The general scope of municipal clerkships is clearly indicated by the expert we have quoted. Under many leading authorities, however, there are higher clerical posts occasionally accessible as heads of departments, committee secretaries, and so forth. The City Corporation, as already mentioned, offers several such prizes. The principal clerk of the public health staff, who has 30 years' brilliant service to his credit, receives £1,800 a year, his colleagues in the chamberlain's and town-clerk's office £1,000 and £950 respectively, and the chief rating clerk £850. The Metropolitan Water Board lately advanced a district secretary to a post commanding a salary of £600, and clerical appointments worth from £500 to £750 a year are similarly won from time to time in almost every busy corporation.

Necessity of Specialising. Such prizes are captured by the men who, being neither routine-bound nor content with the bare qualifications exacted by their work, have specialised as their judgment suggested. And this course is essential for the clerk who is not only ambitious, but resolved to realise his ambitions. Having chosen his work, he must sedulously fit himself for higher office than he holds. Is public health to be his forte? While still a junior he will study the statutes and bylaws, familiarise himself with the system by which they are applied, and by lending a willing hand in the preparation of minutes and reports, and in a score of other ways, will make his services valuable to the chief clerk and the medical officer. Whatever his department, indeed, he will spare no pains to become skilled in the duties attaching to it. In the Municipal Service, controlled as it is to a great extent by amateurs, there is always need of such experts, and they have good prospects of early advancements.

Draughtsmen and Tracing Clerks. These officers, although members of the general clerical staff, constitute a small and special section, unaffected by the ordinary conditions of promotion. They are employed in the departments of the surveyor, engineer, and architect, in the preparation of plans, and allied work. The earnings of tracing clerks are small—from 15s. to 30s. a week. Plan copiers earn from £130 to £180 a year, and the salaries of draughtsmen range between £80 to £100 a year for junior appointments, and £180 or £200 for seniors. A number of draughtsmen and technical assistants are employed by the London County Council's superintending architect (of Spring Gardens, S.W.), who will forward forms of application upon request. These posts are on the "unestablished" staff, and are remunerated at rates ranging from a guinea (for youths) up to 4½ guineas a week. The latter figure is rarely exceeded, or even reached, in this branch of the Municipal Service. Unless, therefore, the draughtsman has received an outdoor training which will qualify him for an assistant surveyorship, his prospects are restricted.

L.C.C. Clerkships. The foremost of local authorities, the London County Council, recruits its staff of men clerks from time to time by open competitions, resembling those of the Civil Service Commissioners, for fourth-class clerkships These examinations are open to British subjects who are over 18 and under 23 years of age on the last day for receiving applications—which is usually a week or two before the contest begins. Candidates must be free from physical defects, and are required, if successful, to undergo a medical examination before being appointed.

The competitions are held as often as a further supply of junior clerks becomes necessary. They are advertised in the chief daily newspapers for several months beforehand. Latterly, two or three examinations have taken place yearly, and a score or more candidates have been selected on the result of each. Now that the Council has become the education authority for London, it is probable that these numbers will be considerably exceeded in future.

Salaries. The subordinate staff of the L.C.C. is classified as follows:

4th class, £80, rising by £5 yearly to £100.

3rd class, £100, rising by £10 yearly to £150.

2nd class, £150, rising by £12 10s. yearly to £200.

1st class (lower section), £200, rising by £15 yearly to £245.

1st class (upper section), £245, rising by £15, and then £20, yearly to £300.

Clerks are probationers for the first year of their service, and the annual increment in every case is dependent on satisfactory conduct.

Beyond these grades are certain special appointments, such as senior assistants (£300 to £400), and principal assistants (£400 to £500), which are usually filled by the promotion of subordinate officers. Fourth-class clerks are promoted to the third-class according to merit, and afterwards according to the nature of their duties.

Pension and Provident Scheme. Unlike the majority of local bodies, the London County Council has a liberal pension and provident scheme in operation, to which each official "on the establishment" pays 2½ per cent. of his salary, being thereupon credited by the Council with rather more than double that amount.

The existing staff regulations have not been working long enough to disclose what are a fourth-class clerk's prospects of attaining an assistantship or other special promotion beyond the £300 limit. However, in view of the regular and fairly liberal increments this employment affords, and the probability that the Council's activities will continue to develop, the opening presented by such a clerkship to a youth of 18 or 19 is certainly a fair one.

Examination Notes. Details of the competitions for L.C.C. clerkships are furnished by the schedule on page 1070. There are several supplementary points, however, to which the attention of candidates should be directed.

Competitors are exempted from Part I. of the examination if they have passed it at a prior contest under the present scheme, or hold any of the following certificates:

(*a*) Matriculation at either London, Liverpool, or certain other Universities.

(*b*) Cambridge Higher Local.

(*c*) Senior Local (Oxford, Cambridge, or Durham).

(*d*) Higher School certificate, Oxford and Cambridge Joint Board.

(*e*) School leaving certificate of London University (or of the Scotch Education Office if higher grade was obtained in three subjects); senior certificate of the Irish Intermediate Education Board or Central Welsh Board; or Preliminary Arts and Science, Scottish Universities Joint Board.

Examination in General Knowledge. Among the novel features of Part II., the most striking is the compulsory examination in general knowlege. This is an ingenious test of the candidate's observation, memory, and intelligent grasp of facts. Its scope can best be judged by these specimen questions from a recent paper:

What do you know of the voyage of the "Bounty," Bushido, the Terrible Cornet of Horse, the Father-in-Law of Europe, Leander, the Magzhen the "Mayflower,," May Meetings, Pidgin English, the Scourge of God ?

Explain the phrases: *Savoir faire; Lèse majesté; Welt politik; Res judicata; Territorial waters.*

What do you know of the Round Towers of Ireland, the Towers of Silence, and Martello Towers?

Give the English names for the following places: Anvers, Bruxelles, Firenze, Génes, Genf, Köln, Londra, Marrakesh, Napoli, Venedig; and state what nations employ these designations respectively.

Classify the British Dominions beyond the sea according to the nature of their respective governments, and state as shortly as you can the points of difference between the several forms of government.

Explain precisely why a ship floats in the sea, and a balloon in the air, and why it is more easy to steer a ship than a balloon.

Definitely to prepare for such questions as these is almost beyond the art of man. Occasional readings in a concise encyclopædia might do much towards it, provided that every passage thus encountered is carefully read through. It will be found that several questions in each set relate to topical or political matters treated in the daily Press. But the student's best course is an indirect one; he must cultivate the habit of grasping clearly all that he reads, and at all costs avoid the fatal trick of "skimming."

Papers on Local Government and Shorthand. Subject 10—Outlines of English local government—is a useful study for future municipal servants; but, despite the textbooks recommended by the Council's syllabus, it is exceedingly difficult to master this topic unaided. Fortunately, however, several Civil Service colleges prepare candidates in this and all other subjects for the L.C.C. examination.

Shorthand is the subject of a special memorandum. It may be taken in Part II. as a special paper, but not for inclusion in the competitive examination. This course is adopted because "there are some positions in the Council's service," as the regulations state, "where shorthand is essential," and as that authority specially reserves the right to appoint a candidate out of the order of merit if he is qualified for a particular post, a good stenographer may win an appointment, even though he takes only a moderate place on the general list.

It may be added that the Council at times requires the services of temporary clerks, who are chosen from a list of suitable candidates kept by the Clerk.

Women Typists. The London County Council employs some 40 of these officials, who are selected by means of preliminary and competitive examinations open to women between the ages of 18 and 30. The qualifying test is a simple one, restricted to general knowledge, including stencil work, and typewriting; but candidates who take shorthand and certain educational subjects in addition may obtain first class appointments as "supervisors and shorthand-writer-typists." For Class II., the rate of pay is £55, rising by £5 annually to £65, and in the upper section to £80. Class I. officials, beginning at £80, advance by a like increment to £100, and on gaining the upper section, rise from £100 to £120. The staff being small, competitions are not frequent; each is duly advertised in the London newspapers a month or two before the actual contest. Particulars as to the examination subjects and the appointments generally, can be obtained at the Council's offices. Several other authorities employ lady typists, after a qualifying examination, at salaries ranging between 25s. and 35s. a week.

MODELS OF SCULPTURED ORNAMENTS

Greek, 2, 7, 8, 10, 11, and 12. Gothic, 1, 3, 4, 5, and 6

SCULPTURE

Flat Modelling. The Tools and Groundwork. Casting in Plaster. Modelling from Natural Forms. Protecting the Parts in Relief. Animal Study

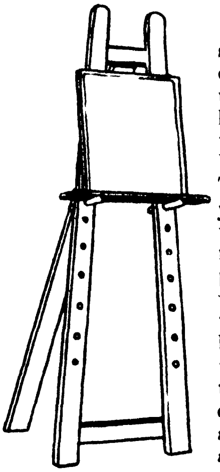
By COURTENAY POLLOCK, R.B.A., and P. G. KONODY

A THOROUGH knowledge of drawing (which is dealt with in a special section) is essential before the student can proceed with the practice of modelling.

Flat Modelling. During the first stages of the study of modelling, only a limited number of tools is needed, though, when the student has acquired some proficiency in handling clay, he may possibly find others which may suit his particular work. For relief modelling, the following are all that are needed :

An easel about 5 ft. 6 in. high, strong, and of the ordinary type, with holes and pegs, with a board 20 in. by 4½ in., to place across the pegs. Upon this you rest your working slab [13].

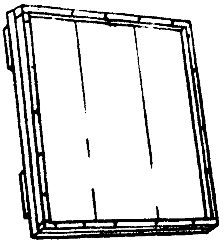
A wooden slab about 18 in. square, clamped at the back by two pieces of wood to prevent warping by the damp clay. Round the edges of the slab a beading should be fixed, so that it rises ¾ in. higher than the slab [13 and 14].



13. EASEL AND SLAB

A few wooden tools are enough to begin with. Choose those of simple form and light to hold. Those shown in 15 are recommended. They can be had at any artists' repository. The slab should be made by a carpenter or joiner, who might, in fact, make the whole easel according to instruction. It is cheaper, and may be stronger than those sold by artists' colourmen.

A piece of damp cloth, or a sponge, on which to damp one's fingers, or to keep them clean while working. Also, a piece of waterproof cloth large enough to cover the model, to prevent drying.



14 SLAB

Clay. Clay can be obtained in 2 cwt. tubs. Get the best modelling clay, which is of a light grey colour, and, when fired, changes into warm buff. See that the clay is kept damp and of a consistency that allows of easy handling by the fingers. If it gets too dry, it is tiresome to manipulate, and does not adhere easily.

With these materials before you, you may begin work by filling the wooden slab with clay. It is shaped something like a tray with raised edges. Press the clay firmly into the slab, filling it entirely and solidly—leaving no holes—and press down with the hands to a level very slightly higher than the surrounding border. Take the straight-edge shown upon the easel [13], and level down the clay by pressing the straight-edge backwards and forwards over the surface, the ends of the straight-edge resting on the edges of the slab.

When the clay surface is quite smooth, place the slab upon the easel, and begin to draw your ornament upon it with one of the straight tools, which must be held freely between the thumb and fingers, as in drawing with charcoal, not as one would hold a pen. Draw lightly, and it will be easy to correct mistakes.

Laying on the Clay. Take now some fresh clay, roll it into lumps of convenient shape and size, and lay it upon the drawing, filling in the outline and adding where it is necessary to obtain the required height of relief. Use the fingers as much as possible. Tools only serve as a help. The more you use your hands the more quickly will you become accustomed to the feel of the clay, and you will gain in precision. The fingers should not be wetted more than is necessary to keep them clean. You will learn nothing by smoothing the surface of your work. The essential point at first is to endeavour fully to understand, not only the shape of the flat outline, but—and this is more important—the shape and relative projection of every part, noting their mutual relation, and striving to imitate this, so that your own model shows exactly the same light and shade as the example you copy.

While working, you should keep your model and your own copy in the same position, without turning them to get a variety of views ; although this may be done when you have carried your work to a point at which you begin to feel satisfied that it is a good copy. At this stage, it is helpful to turn both models upside down. You will probably see at once that your copy is not as good as it appeared in its original position. Do not, however, work in any but the original position. Having once satisfied yourself where you are wrong, turn both models to their upright positions and proceed, correcting the mistakes from a diligent study of the points where you have failed. In this manner, the eye will soon become quick to notice errors in proportion and drawing.

Examples to Copy. For elementary work, one cannot do better than secure a few—say half a dozen—simple casts, such as the Greek examples, or the casts taken from Gothic stone carvings [1-12]. Avoid complicated designs ; their intricacy does not teach much. The models should be simple as regards general outline, and rather bold in relief. Avoid geometric designs; they are often quite useless, and are never interesting to copy.

Casting in Plaster. Tools must again be considered first:

An ordinary "crock" bowl, such as those used for boiling puddings. Choose a large one, of about 12 in. in diameter.

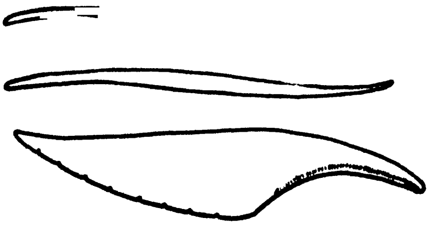
A galvanised iron spoon, such as is used for basting, to stir your plaster; a wooden mallet, small and light, and two chisels, one broad and one fine.

A small quantity of oil—sweet oil, linseed, or olive—the latter is best. Some raddle, blue powder colour, or ochre, tied in a piece of muslin, and two ordinary soft hog-hair paint brushes—one large, for washing out the inside of the mould, the other small, for applying the oil.

It is necessary to have a good water supply at hand, and also a few pieces of square iron rod, ⅜ in., cut in lengths of from 15 to 25 in. These are useful sometimes to let into the back of the cast to strengthen it, although they are not always necessary.

Some soft soap. A pound tin will last some considerable time.

A steel tool, such as is used by plasterers [16]. This is needed to retouch the cast where the chisel has scratched or bruised the surface during the removal of the waste mould, and can be bought at any good cutler's, one being sufficient, if well shaped, as in illustration.



15. MODELLING TOOLS

For this fine casting, none but the best Italian plaster should be used, which is obtainable at any Italian plasterer's. The "best plaster" sold by oil-stores or colourmen is quite unfit for the purpose. Buy your plaster in half bags, and keep it in a very dry place.

16. STEEL PLASTER TOOL

Making the Mould. Before the casting is proceeded with, sawdust should be spread upon the floor, to prevent the splashes of plaster from adhering to the floor boards.

Supposing the clay model to be 18 in. sq., it will be sufficient to fill only half of the bowl with clean water. Into this water dip the small muslin bag containing the dry colour, and leave it there for a few seconds, removing it when it has tinged the water with a dark colour. Take the plaster from the bag with your hand, and allow it to sift quickly through the fingers into the coloured water, until it rises to a level almost with the top of the water. At once stir it vigorously with the spoon, using the action you would employ when beating an egg, but keep the spoon below the surface, or you will throw the plaster about.

The operation must be done quickly, or the plaster will become lumpy. Do not stir whilst filling the bowl, as this may render the mixture quite useless. Place your clay model flat upon the table, and, for convenience, place strips of clay round it to form a wall about an inch high. Pour the coloured plaster over it quickly, completely covering the model. Take it up, and, holding it horizontally, shake it quickly backwards and forwards, and from side to side. Then at once pour off the plaster into the bowl, leaving a thin coating on the clay model. Air bubbles are then removed by blowing into the cavities.

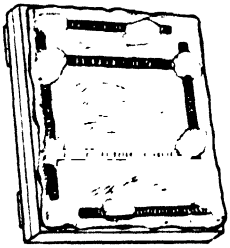
Protecting the Parts in Relief. Again pour on the contents of the bowl, and. after raising and lowering your model so that the plaster shall flow over all the surface again, pour off the superfluity very gently, and let the model rest. It is advisable now to take a little plaster from the bowl and drop small lumps upon the highest points of the relief. This will protect the high parts, and, in the chipping away of the *outer white portion* of the mould, indicate the nearness of the actual cast. Leave the model for about 8 or 10 minutes, until the plaster is quite firmly set. In the meantime, clean your bowl, and fill it again with water, without using the colour bag.

Before proceeding to thicken the mould with the white plaster, brush lightly over the coloured coating with oil, using the small brush. Very little oil should be used, or the coloured plaster of the mould may come away from the white too early, and thus ruin the cast. Now fill the bowl to within an inch with water, and sift into it the white plaster, riddling it through the fingers as before, until it appears on the surface; stir well, and pour it over the coloured coating to a thickness of about ½ in., increasing this at the edges, to strengthen it. If the clay model is in high relief, and the mould thin in places, it may be necessary to place two or three pieces of the iron rod round the edges, and a couple across the back, fixing them in position by dropping a little plaster upon them here and there [17].

Removing the Clay from the Mould. When this is set hard—which should occur in 15 minutes—turn the whole over upon its back and remove the wood slab. Should this be difficult, a little water should be run in between the board and the clay, after the removal of the small clay wall which was added before beginning the mould. Take out all the clay, using one of your wooden tools where the fingers cannot reach. Be careful not to scratch the surface of the mould. Then wash out the mould with plenty of water, using the large brush. Every particle of clay must be carefully removed. Now take some soft soap, and, having rinsed the mould thoroughly, lather it well with the brush until the surface has a good shine. Plentiful use of soap lather will sometimes do away with the use of oil, but it is advisable to pass a little oil over the projecting portions of the mould, to facilitate the removal of the coloured portion in the process of chipping it away.

The operation of filling the mould and draining the plaster off again, is now repeated several times, until the fresh plaster is about 1 in. thick all over. It should be given time to set, as the cast might crack if chipped too soon.

Chipping. Now turn the whole over and lay it upon some soft material, say a sack. With the broader chisel, chip off the iron rods and the thick covering of white plaster. The high points of coloured plaster will appear first, and thus indicate the thickness of the plaster to be removed, and give roughly the outline of the design. Remove all the white portion of the mould; then, very delicately tapping with the small chisel, gently remove all the coloured coating. The amount of retouching required will depend on the degree of care exercised. The very small pieces of the mould are removed with the small end of the steel tool shown in **16**, which is also used in filling in with fresh plaster scratches and abrasions made by the chisel.



17. BACK OF MOULD

Modelling from Natural Forms. When the student has acquired fair skill in handling the clay, he should seek suitable forms in Nature for study. The diligent study of foliage, flowers, and tree-growth—in fact, of practically everything in Nature that the student can intelligently copy—will help him more than a lifetime spent in making copies of other people's work, however good they may be. It will give *knowledge*, which is the most potent factor in the education of an artist.

Small sprigs will do for the beginning. It is not at all necessary to select a sprig on which the leaves seem to grow in a pleasant arrangement. Take any sprig that has not been damaged, no matter how ill-balanced it may seem. Nature does not make mistakes, and you are not designing now, but learning the growth of Nature. The springtime affords ample opportunity for studying development in Nature. The gradual development of the leaf-buds, for instance, is irresistibly interesting. Take a sycamore bud and look at it carefully, noting the angle at which it grows upon the stem, and observing how the leaves are bursting through their cover in the most wonderful forms.

The student cannot do better than stick some of these buds on his clay slab and make a number of studies of them, till his memory has retained the forms from the bud to the full leaf. The same minute study should be carried into the consideration of the stems and trunks of trees. In some cases, where the detail is too fine for clay, pencil studies will be found helpful, but one can, as a rule, correctly suggest the detail, if one understands what one is copying, and is satisfied as to its shape and appearance. The beautiful flower known as "Love in a Mist" is a good instance. It is quite impossible to copy every bit of the fine, fibrous mass which surrounds the flower, but careful observation and a little thought will enable the student to represent it, by suggestion, on his clay. However, for the purpose of learning how to *model* plant form, it is best to select plants of simple, bold form, and to depend more upon pencil studies for learning the plant itself.

Animal Study. The study of animal forms should follow that of plant form. Several books have been published containing photographs of animal life, but we cannot recommend the practice of working from such plates, because the photographs do not sufficiently explain themselves, and their study is neither interesting nor very instructive. If very good and clear, and of fairly large size, they may be useful at times in affording opportunities for studying such details as are not affected by movement; but it is infinitely preferable to study from the living subject, and not at all necessary to make the studies in the clay direct. In fact, the student will learn more quickly if he depends upon pencil studies when working from live animals. Such studies allow him to record movements, and consequent change of surface forms, which are impossible to make note of in clay.

The constant movement of the animal may be troublesome. When you have seized the chance offered by the animal's lying down, and have half completed the drawing, the model will change the pose of its head, or rise and seek a more comfortable position. This need not worry you. If the unfinished drawing has been done with care and thought, it is useful, and has taught something.

Many students consider a study incomplete if it is fragmentary. This is an error. To learn what an animal is, and how it moves, it is not at all necessary to make laborious drawings of the complete creature; much may be learnt by quick and limited "notes."

APPLICATIONS OF HYDROSTATICS

The Hydraulic Cylinder and Ram. Hydraulic Jacks of Various Types. The Punching Bear and Wheel Press. Hydraulic Lifts and Cranes

By JOSEPH G. HORNER

Hydraulic Rams. Pursuing the applications of hydrostatics into varied mechanisms, we find that the most important is the hydraulic cylinder and ram. In this appliance a solid ram or plunger fits within a cylinder into which water under pressure is admitted, thereby causing movement. The cylinder, or else the ram, is set in motion thereby. Generally it is the ram that moves, as in the hydraulic platform or station lift, and in baling presses, or flanging presses, types of a hundred other machines. But sometimes the cylinder is made free to move over the fixed ram, the alternatives being matters for convenience. Obviously, too, the positions of the mechanism are of no importance. Though in most cases set with the axis vertically, they are often horizontally, and in some cases inclined. Also the lift may be direct, the table platform, or platen, being attached to the head of the ram. Or chains may be brought round pulleys at the head of the ram, and, with suitable anchorages, used to impart motions that are not in a direct line with the movements of the ram. These occur in jigger hoists, and in many kinds of hydraulic cranes. Pressure is also often transmitted by jointed or walking pipes instead of rigid ones, to avoid having to reconnect, as in hydraulic riveting plants.

It should now be readily seen that, given the foregoing elements, capable of producing strong pressure and transmitting it by a liquid which is practically incompressible, enormous possibilities in application are opened up. The following are a few examples which are selected from a much wider practice, and each of which occurs in machines the details of which are modified in many ways in the hands of different manufacturers.

The Hydraulic Jack. This is a simple machine for gaining enormous power, but with its accompaniment of very slow movement, resembling in this respect the differential pulley blocks. Both are invaluable when heavy loads have to be lifted by human energy alone. The jacks will lift locomotives, ships, bridges, by the operation of a hand lever, and in modified forms they will push loads slowly. They are emergency tools out of doors, where cranes are not available. Their general construction is shown in **148**, which represents a Tangye lifting-jack that combines two functions in one—that of lifting on the head A, and also on the foot B, the latter being an invaluable addition when there is little space between the object to be lifted and the ground. The construction of the jack is as follows.

C is the body of the force-pump, and D its ram, actuated by the lever E, drawing the water from the cistern F, by the pressure on which between the ram G and the casing J the latter is forced upwards. In the force-pump CD we recognise the same type of pump that was illustrated in the previous article [page 1083]. The difference in the area of its ram D and that of the ram G of the jack represents the theoretical gain in pressure.

Operation of the Jack. When in operation, the cylinder J should first be down to the bottom of the ram, as shown by the drawing. The cistern F is then filled with liquid, either by removing the cover A or by taking out the charging screw H and filling through its hole. Clean water must be used, or rain water, or condensed steam with ¼ oz. of soda added. In cold weather glycerine is added to the water to prevent freezing—one part of glycerine to three of water. The lowering screw, or stop-valve K, is then unscrewed, and the lever E, pivoted at *d*, worked a few times, by which means water is forced through the pump into the space L, and any air present passes through the valve K into the cistern F. A little more water is added through H to take the place of the air driven out. The air-screw M is left slightly opened all the time to allow freedom of escape to the air. The cylinder J rises on the ram G until the water comes out of the blowhole N, though it is not well to lift to the extreme limit, as the leather packing (*c*) is liable to become damaged.

To lower the jack, the screw K is slackened, which leaves a free passage of the liquid from L to F. If the height to which a load has to be lifted exceeds that of a single "run-out" of the jack, then the jack is raised on blocking, and another lift taken.

There are a good many practical points about the working of these jacks, but only one can be referred to here—the care of the leather packings (*c*). Nothing yet has been substituted successfully for leather, so that the old saying "nothing like leather" is in this connection absolutely true. A peculiarity to be noted is that the leather is cupped in such a way that the harder the pressure the more tightly is the leather pressed out against the walls of the cylinder. Sometimes even a leather which will be leaking when a ram is doing no work will cease leaking as soon as a load is put on. The troubles to which leathers are liable are mainly due to their drying and shrinking. Next to these the presence of grit is most harmful. When leathers have to be cleaned they are taken out and soaked in water or oil.

With regard to lifting a load on the claw B, it is obvious that the full load which can be taken on the head A cannot be put on the claw. It is, therefore, not judicious to carry more than

HYDRAULIC PRESSURE MACHINES

25 per cent. of the jack-load on the claw if the lifting be a high one. For a short lift nearly the maximum load may be carried with safety.

Modified Jacks. Around this simple mechanism, which is but a modified form of the essential Bramah press, engineers have built many designs, a few of which we shall now notice. Some of the reference letters are retained in the subsequent figures for the purpose of ready identification of similar parts.

Given the jack itself, one of the first improvements effected with a view to increase its range is to impart a horizontal motion bodily to it—the *traversing jack*, a movement effected by a screw. An object after being lifted can thus be moved along bodily within a limited distance.

Ship Jacks. Jacks are utilised for lifting ships, hence termed ship jacks [**149**], though, of course, suitable also for bridges and other heavy works. Here we recognise the force-pump, but set in a horizontal direction, and operating a vertical ram. But while the jack in **148** is made for loads up to about 50 tons, the ship jack is made as high in power as 400 tons, which explains the enormous disproportion in the diameter of the rams D and G in **149**, the drawing being made to scale. Note also the great thickness of the metal in the cylinder J which encloses the ram, and receives the pressure tending to rupture it. The only other differences that need be noted are the form of the packing leather, and the safety-valve in **149**. The leather (c) is of the U section, that being more suitable than the cup form in **148** for withstanding enormous pressures. The weighted safety-valve lever O, though often omitted, is desirable because of the severity of the pressure, which, if much exceeded, might rupture the cylinder or the pump. The power of this small jack is thus equal to the lifting of four of the largest locomotives with their tenders.

Pulling Jacks. In these examples the power is applied to the exercise of thrust or push, but it is equally applicable to a pull. A special form, therefore, is the pulling type [**150**]. There are confined spaces where even the snug pulley-blocks cannot be used to pull a load, as in shaft tunnels, and sometimes in the engine-rooms of steamers, and then the pulling jack, operated by a pressure pump, is a boon to the men who have to execute hurried repairs.

This jack has the same cistern, force-pump, and stop-valve, but a tube (G) takes the place of the ram, and the water pumped from the cistern passes through the bore of this tube to the underside of the piston. The latter forms an enlargement at the end of the tube, and has a U leather packing (c). The eyes fitted at the ends are in union, one with the cistern and thence with the tube, the other with the cylinder for connecting to the work, and to any suitable point of attachment. In operation, the tube is drawn out as far as is required, and the act of pumping pulls it in, drawing the work along with it. The jack is used indifferently in a vertical or horizontal position. Machines of this kind are made with powers as high as a 25-ton pull, with a maximum run-out of 36 in.

The Punching Bear. Nor is it only in pushing and pulling that the coercion of pressure-water is in evidence. The same essential mechanism—that of the small ram of a pump and the large-power ram—are used for punching holes through steel, and for shearing the edges of steel sheets. Fig. **151** shows one of the first variety, which is made by Messrs. Tangye, of Birmingham, a most useful machine, termed the punching bear. Its utilities lie in the formation of holes in girders and other plated work in localities which do not admit of the utilisation of the fixed power operated machines. A man or two men can handle this machine, yet it is powerful enough to drive rivet-holes through iron plates ¾ or 1 in. thick.

The top lever E actuates the force-pump, and sends pressure-water into the chamber above the ram G, pushing the latter down. The punch P being fitted into a hole in the latter partakes of its movement. The function of the lower lever Q is to raise the ram and punch, previous to which the stop-valve must be opened to allow of the escape of the water back into the cistern.

Around this design many larger punching machines are built for special work. They include machines for punching tram rails, girders, channels, and copper sheets. Some are portable, being mounted on wheels for movement to work in progress, on railways, and in streets. Some have so little resemblance to others that a superficial observer would hardly see the relationship, but they all embody the same principle—that of the Bramah press. Some, too, are used for closing rivets. Also, by substituting shear blades for the punch and its bolster, we have the hydraulic shearing machines, a large group.

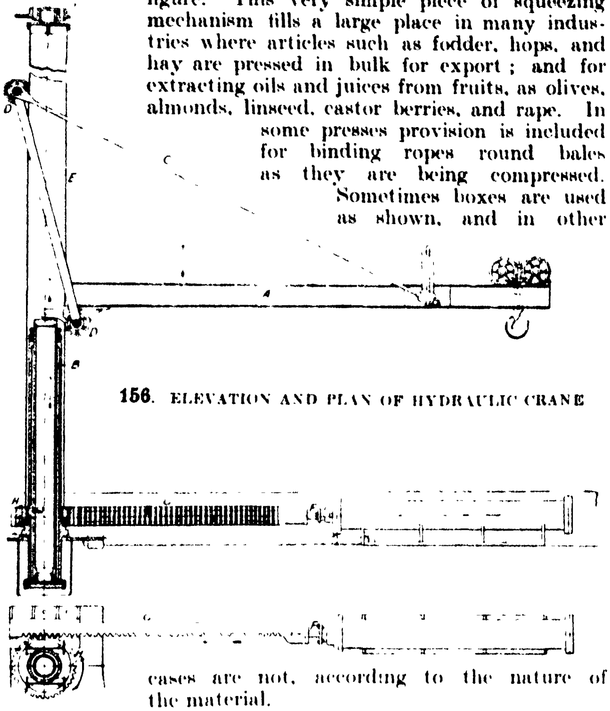
The Wheel Press. This is a machine for pulling railway wheels on their axles, and taking them off by the simple exercise of water-pressure. The wheels on their axle are slung between heads, which afford the necessary resistance to the water pressure. They are capable of exercising total pressures ranging from 80 to 200 tons. Many of these are worked from an accumulator.

Bolt Forcer. The same principle is adopted in the bolt forcer [**152**], a small machine which pushes bolts home, and rusty ones out of their holes. They are capable of exerting pressures of from 20 to 75 tons on a refractory bolt. The ram here (G) is hollow, to receive a steel drift (P) which is forced along by the ram against the tail of the bolt to be pushed out. The resistance is taken by the arms or claws Q, two in number, so flanking the bolt on each side. A propeller shaft with a bolt about to be forced out of the flange is indicated in dotted outlines. The arms (Q) have handles for lifting and transportation. Figs. **149**, **150**, and **152** illustrate examples from the practice of Messrs. Youngs, of Birmingham.

Another machine forces the big propellers of ships off their shafts by the persuasive power of a little water judiciously applied.

Yet another group identical in principle of operation include the bending and straightening machines. These may often be seen in the streets where tram-lines are being laid down. Pressure either to bend or straighten is applied between the end of the ram and a pair of claws, or hooks, opposed thereto, and to right and left, the rail being gripped between so that the pressure takes place at three points. Pressures of 40, 50, or 60 tons are thus obtainable.

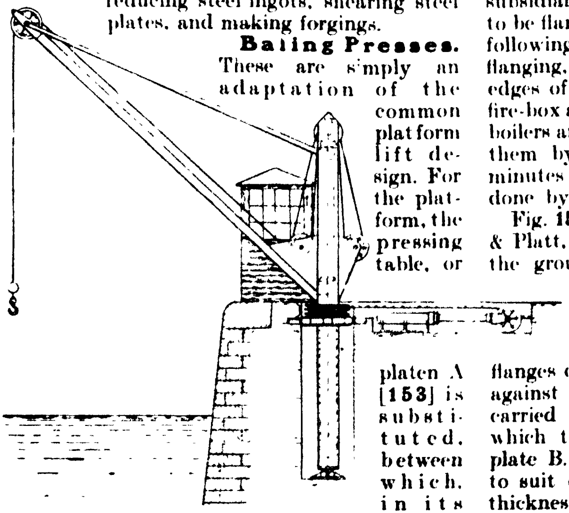
In the shops there are larger machines used for straightening steel beams, precisely the same in essential mechanism, but differing in outline, being fixed on massive bed-plates. When steel girders, joists, bars, and other sectional forms have to be either bent or straightened, this is not done by the brutal method of hammering, but by squeezing. The machine may be described as a hydraulic jack (the ram) so mounted as to push the girder or beam in opposition to two points of resistance. Being under control, the pressure can be arrested when the beam is either straightened or bent to the curvature required



156. ELEVATION AND PLAN OF HYDRAULIC CRANE

Presses Using Accumulators. The members of this group are as numerous as those we have already considered, and they are generally much more massive in form. The most familiar are those for lifts for passengers and goods, for pressing or baling, flanging, squeezing and reducing steel ingots, shearing steel plates, and making forgings.

Baling Presses. These are simply an adaptation of the common platform lift design. For the platform, the pressing table, or platen A [153] is substituted, between which, in its upward movement and the head B of the machine, fixed above, the loose material is pressed, often with a force of from two to three tons on every square inch. Hay is pressed thus into a bulk one-sixth that of the original truss. The motive power is still the force-pump and accumulator actuating the ram C in the figure. This very simple piece of squeezing mechanism fills a large place in many industries where articles such as fodder, hops, and hay are pressed in bulk for export ; and for extracting oils and juices from fruits, as olives, almonds, linseed, castor berries, and rape. In some presses provision is included for binding ropes round bales as they are being compressed. Sometimes boxes are used as shown, and in other cases are not, according to the nature of the material.



157. HYDRAULIC CRANE

Flanging Presses. These are a special variant on the baling press and kindred types. They contain more mechanism, in the form of subsidiary side-rams, that push the boiler plate to be flanged up against one die, which is fixed, following which the main ram pushes the flanging, or movable die up, so bending over the edges of the plate against the fixed ram. The fire-box and tube-plates for locomotive and other boilers are turned round thus, instead of flanging them by hand, the process occupying a few minutes against hours required when they are done by hand hammers.

Fig. 154 illustrates a flanging press by Fielding & Platt, Ltd. The cylinder and ram are below the ground, as in the baling press, but only the top of the ram is shown in the figure, at A. This lifts the movable plate B, which carries the lower flanging die C on stools, which die flanges or turns over the edges of the plate G against the edges of the upper die D. D is carried by stools against the fixed plate E, which thus resists the pressure of the lower plate B. E is, however, adjustable in height to suit different pieces of work and different thicknesses of dies. Before the actual flanging of the plate G takes place, the plain plate is brought up and held against the upper die D by the plate H, which has a vertical movement independent of that of B through four small hydraulic rams J. The object of this provision, distinct from the squeezing, is to permit of making precise adjustments of the plate before flanging it. Hundreds of these machines are in use, doing work with a silent squeeze better, as well as more quickly, than hand work was ever capable of doing.

Forging Presses. These form an immense group, comprising machines more or less specialised. The largest forging press in the world is the 14,000-ton press of the Bethlehem Steel Works. There are some immense presses in Sheffield for forging down ingots for armour plates. Essentially they comprise the ram and cylinder. They have entirely displaced steam hammers for the most massive work. It would be impossible to forge the big propeller shafts and the guns and armour plates by steam hammers with sound results, to say nothing of the concussion of hammers, which does not exist with presses.

In forging presses are included large groups which deal with comparatively light work, which they bend and mould in all conceivable shapes. At the Swindon G. W. R. Works and elsewhere there are numbers of these presses in a great shop in silent operation making buffers, horn blocks, and the numerous forgings required for carriages and waggons.

Lifts. In the direct-acting lift [**155**] the hydraulic cylinder A is sunk in the basement. By the admission of pressure-water from the accumulator, the ram B is lifted. As it carries the platform C on its upper end, the platform partakes of the lift movement, and is carried up to a distance corresponding precisely with the amount of vertical travel of the lift. The descent is accomplished by gravity, by letting out the water, the rate of which is under control. The capabilities of this simple mechanism are almost without limit. Two extremely powerful installations of this kind are the canal lifts at Les Fontinettes, and on the Canal du Centre, Belgium. In the latter a trough of water, weighing 1,100 tons, and containing a barge, is lifted to a height of 50 ft. in 2½ minutes. This load is sustained by one ram 6 ft. 6¾ in. diameter, and the pressure is 470 lb. to the square inch. On the Neuffossé Canal, at Les Fontinettes, similar lifts, but weighing 700 tons, are lifted 43 ft.

Hydraulic Cranes. As these were the first mechanisms to which water pressure was applied (by Armstrong, at Newcastle), so they are still used to an immense extent for light as well as heavy loads. Details vary widely from the plain types shown in **156**, **157**, to the vast coal-tips which lift a 20-ton waggon of coal, tip it, and return the waggon to the rails in a minute.

The crane shown in **156** is of the direct-acting type—that is, the jib A with its load is lifted by the upward movement of the ram B. The jib is steadied by the rods C and rollers D above and below against the post E. The rotation of the jib is accomplished by another ram (F), set horizontally, and moving a rack (G), turning a wheel (H) that encircles the post E. More often a chain is used for turning, as indicated in the skeleton drawing **157**. In this example the lifting of the load is done with a fixed jib. The ram is shown at the top of its stroke, and its movement draws the rope or chain round the pulleys shown, so lengthening or shortening the lift at the hook.

Other Applications of Hydrostatic Pressure. The foregoing is a small but representative selection of the utilities of power-water. The following is a short summary only of other ways in which hydrostatic pressure is employed in engineering structures.

It is applied in many turning operations, for, as we have seen, the cylinders can be arranged in any positions, and connected by chains or racks and pinions to the parts to be moved. Hence we have it working the steering gear of the largest ships, for which hand power would be utterly incompetent. Large swing-bridges are operated similarly. There are many of these in existence for road and railway traffic. One of the latter, over the River Ouse, at Goole, weighs 670 tons, and is actuated by engines having three cylinders arranged radially, and worked by water at a pressure of 700 lb. per sq. in. One over the River Tyne weighs over 1,200 tons. The huge bascules of the Tower Bridge are raised and lowered by hydraulic engines, besides which the hoists for taking foot passengers up to and down from the high-level footways are actuated hydraulically.

Dock gates are opened and closed by hydraulic rams, arranged horizontally, and connected with chains to the gates. In other cases the chains are wound on to, or unwound from, drums by hydraulic engines. Docks having openings as wide as 100 ft. have their gates opened and closed thus by pressure-water.

Big guns are also manipulated hydraulically, and the recoil also taken thus.

Mention has been made of the hydraulic punch, the shearing and flanging machines, but these are only faintly representative of the vast utilities of the pressure-water in our factories and on public works. Numbers of distinct and separate types of machine tools, some fixed, others portable, are in use in nearly every big engineers' works and on great public structures. A modern boiler is never built without the aid of these tools; seldom, if ever, is a bridge erected or a steel ship constructed without their having a big share in the work. It would be difficult to say which is the more useful—the heavy, fixed machines, or the lighter, portable kinds. The latter enable many operations to be performed that a few years ago were deemed impossible except by hand work—operations done in awkward situations and where the work is too massive to be taken to any machine. Holes are punched and drilled, rivets closed, and steel cut, control being exercised by the movements of simple valves operated by handles. But the power behind it all is the pressure-pump and the accumulator, with its storage.

COOKERY

Kitchen Requisites. Kitchen Ranges and Gas Stoves. A Marketing Guide. Care of Kitchen Utensils. Substitutes for Scales

Continued from Page 1004

A PROPERLY-EQUIPPED kitchen is a matter of no little importance. Any apparatus which is time, labour, or money saving should be eagerly sought after by an intelligent mistress who wishes to facilitate the cook's work. Nowadays, most of the necessary utensils are well within the means of the average housewife, if she does not allow herself to be tempted by the showier and more expensive varieties of the same thing. On the other hand, very cheap goods are not true economy. On all sides one is met by fascinating, artistically coloured enamel-ware, often labelled "bargains." In many cases the enamel cracks the first time they are used—notably the frying-pans. Once cracked, it will burn easily, and not infrequently fragments get into the food, which is, of course, a source of great danger. There is also a risk of arsenical poisoning with inferior enamel.

Useless Utensils. Very cheap tinware has much the same objection—spouts drop off, and handles come out if used for any more powerful heat than a spirit lamp; though good blocked tin is a light and very useful metal for fish-kettles, light tea-kettles, etc.—providing rust is carefully guarded against.

Copper pans are most durable. They are handsome in appearance and excellent conductors of heat; but they are expensive, and the greatest care must be taken to keep them scrupulously clean, and to note that the tinned lining does not get out of repair, or fatal cases of verdigris poisoning may occur.

Perhaps the seamless sanitary steel pans are as serviceable as any. They are practically everlasting, easily re-tinned, and less expensive than copper. There should, of course, be a few tinned, and enamel-lined iron ones for harder wear.

The steamers with several compartments over one boiler are most useful and economical, and it is a pity that the handy little Dutch oven is not more patronised—it is such a capital invention for all grills, toasts, and for roasting small birds.

The "Bain-marie." Another invaluable utensil but little met with in ordinary kitchens is the *bain-marie*. It is a shallow pan, about 8 in. or so deep, which stands on the stove, and is kept half full of boiling water. Into it are put all saucepans the contents of which need keeping hot without becoming dry or boiling. If a complete *bain-marie*, with pans to fit, cannot be afforded, the pan itself could be procured or made in some strong metal, and the ordinary household pans fitted in. Casseroles, a "hot-pot," a few fireproof-ware dishes, a frying basket, hair and wire sieves, a forcing bag with a few pipes, one or two French cooks' knives, vegetable cutters, and a mincing machine are amongst some of the very desirable apparatus in a modern kitchen, and will be found to aid greatly in giving a finish and a professional touch to many dishes which otherwise would appear quite uninteresting.

Care of Kitchen Utensils. Nothing is so disheartening to a careful housewife as to see the kitchen appliances in which she took such pride, and perhaps had some little difficulty in purchasing out of her housekeeping allowance, going to rack and ruin during the reign of some careless or ignorant cook. Many mistresses are, however, so uncertain as to the way a saucepan should be cleaned, and what is necessary for its cleaning, that they cannot judge if proper methods are used.

SUPPLIES FOR THE SCULLERY.

Soda
Dry Soap
Scouring Soap
Emery Paper
Silver Sand
Whiting
Pieces of old woollen material to rub with
Saucepan Brush
Scrubbing Brush
Dish Cloths
Bath Brick

There is no need for scullery work to be made the untidy, unpleasant business it so often is. Dirty utensils should be quickly washed instead of being laid aside till the next morning, or till the grease is cold, and mixtures set and hard.

Pieces should be scraped into one plate, and knives stood upright in a jug of hot soda-and-water so that the handles are not discoloured and loosened by being put into boiling water.

Saucepans. All dirty pans should at once be filled with water and a little soda, so that instead of becoming dry the scraps sticking to them soften and are twice as easily cleaned.

If saucepans are burnt, they should be filled with cold water, some soda added, and the pan left to boil on the side of the stove for about an hour, when it may be easily cleaned.

Any saucepan, no matter of what it is made, should be scoured inside and out. The absurd idea that the hand should be used to rub the pans is happily dying out; a saucepan brush and a piece of stout, rough stuff, first soaped and dipped in silver sand, and then well rubbed over the saucepan is all that is needed—with the addition of "elbow grease."

Enamelled pans should not be washed with soda, which causes the enamel to discolour and crack. Sand also is too sharp, it scratches the glaze. The cloth should be dipped in some fine ash or crushed egg-shells to remove stains.

Never tolerate a soot-coated pan, it wastes fuel and time whilst the heat is penetrating.

Keep all pans bottom upwards in a dry place, with their lids neatly beside them or hung in graduated sizes on the wall. Pans not turned over, and left with their lids on, are not infrequently dirty if an inspection is made.

Rust. It should be remembered that rust and dirt in utensils mean ruin to the delicate flavour of foods cooked in them.

Copper pans or moulds well repay labour expended in cleaning them. After scouring inside and out, brighten them by putting some silver sand in a saucer, add to it a little salt, and moisten it well with vinegar. Dip a piece of cloth in this mixture and rub the copper part *only* with it; a used half of a lemon can well take the place of the cloth. Then rinse it well in cold, soapy water, and dry it. On no account let this acid mixture touch the tinned parts, as it stains them badly.

It is recommended by several good authorities that to keep copper bright for several weeks the outside should be dipped in boiling ale and placed near a fire to dry, but *not* wiped.

Frying-pans, and omelet pans specially, should not be washed, as it is apt to cause the food to stick. All pieces adhering should be scraped off, and the pan rubbed over with pieces of soft paper till clean. Give a brisk rub with a dry cloth and put the pan away in a dry place.

To Polish Tins. If tins are at all greasy or burnt, they must be first washed in hot soda-water and scoured by dipping a piece of well-soaped cloth in silver sand, rubbing them all over with it and then rinsing them.

When dry they should be polished by mixing a little powdered whiting to a paste with cold water, rubbing it well on, and polishing it with a soft, dry cloth or leather. Be sure and brush it well out of all corners, avoid putting on too much, and let it dry a little before polishing.

Wooden Goods. In scrubbing wooden goods do not use soda, as it makes the wood a dirty yellowish colour. Wring out the flannel in hot water, and soap the scrubbing brush. Wash over the wood, then scrub it well, following the lines—that is, the grain—of the wood with the brush. Rinse off the soap thoroughly and dry well. To dip the brush in sand is a very good plan, and whitens the wood; but great care is needed to rinse it well off again.

A Scouring Paste. For very dirty tins and wood long neglected, and, indeed, for any cleaning of that kind, the following preparation is invaluable:

1 pound of soft soap
1 pound of silver sand
1 quart of boiling water
1 pound of powdered whiting
1 tablespoonful of salt

Put all in a saucepan. Stir and boil well for about fifteen minutes. It may be kept for a long time. For wood, use it in place of soap and sand.

Cooking Stoves. It is unfortunate for the head of domestic affairs when the stove is inferior or faulty; there are so many excellent makes on the market that it is a condition of affairs which ought not to be tolerated. Those in most general use are open ranges, closed ranges, and gas stoves. The most useful combination is a range which, by a simple contrivance, can be converted into either an open or closed stove—and a gas stove, as well, for boiling the kettles for early cups of tea, hot weather cooking, etc.

An Open Range is to be recommended for ventilation of the kitchen, comfort and a cheerful warmth, airing linen, roasting meat.

A Closed Range is superior for cleanliness, saving of wear and tear of the pans, etc., simplicity of regulating the heat, economy of fuel (if the dampers are understood), personal comfort when cooking.

Management of Stoves. To manage any stove successfully, it should be remembered that:

1. Perfect cleanliness is essential: dirty, greasy ovens with a charred deposit from various bakings will ruin the flavour of any foods.

2. A flue is a passage like a small chimney leading—one from each of the two ovens and the central fire space—into the large chimney. Through the flues is drawn *up* the hot air, smoke, and flame, to be replaced by a *down* current of cold air, thereby causing the necessary *draught.*

3. Dampers are metal plates, like horizontal shutters, jutting out across the flues behind the back of the range. These dampers can be pushed in to cut off the draught by closing the flue, or give free access to the air by leaving it open. Any intermediate position between "pushed in" or "pulled out" can, of course, be adopted.

4. The stronger the draught, the quicker and fiercer will be the heat of the stove.

5. Soot is a non-conductor of heat. It wraps up the ovens and boiler in a soft woolly covering, through which it takes a long time for even a little heat to penetrate. It also chokes up the flues, preventing draught.

6. The stove should not "roar," as it is called, or become red hot. It indicates that the fire is "drawing" too quickly—that is, there is too great a draught—with the result that the coal is consumed in an extravagant manner, and the redhot surface dries the air, making it very unhealthy. Roaring can be quickly checked by putting in one or more dampers, closing the door in front of the fire, and pushing in the ashpan under the fire.

How to Manage the Dampers. When first lighting the fire, pull out all dampers; usually there are three.

If much hot water is required, push in the dampers over the oven and leave the centre one out.

For baking, pull out the damper over the oven that is required, and push in the centre one and that over the oven which is not needed. If both ovens are wanted, only push in the middle damper.

If the ovens are getting too hot, push the damper half way or right in.

If the fire is to be merely kept in a little—say, between luncheon and tea-time—push all the dampers nearly, but not quite, in.

Remember that, unless one damper is left, at any rate, a little out, there will be no outlet for the smoke, and it will pour out of the top of the stove.

How to Save the Coal.

1. Have all the cinders sifted to mix with the coal.

2. Select a hard coal for the range, or mix it with coke.

3. Burn all possible kitchen refuse when you can afford to slacken down the fire.

4. Regulate the dampers carefully.

5. Keep the flues and spaces over the ovens free from soot, so that they heat quickly.

6. Keep the fire well made up, stoking it frequently, but only putting on a little coal at a time.

When to Clean the Stove. The chimney should be swept at least every six months.

The flues must be brushed thoroughly at least once a week, or oftener, if a very soft coal is used or a great amount of cooking done.

Brush well over the tops of both ovens every morning.

Wash the inside of the ovens well—the shelves, sides, and door—at least once a week, with hot soda-water. Use a stiff brush, and, if necessary, scrape the shelves with an old knife.

Gas Stoves. These have nowadays been brought to a very high pitch of perfection, and are an enormous convenience in districts where gas is laid on, and the rates are not so high that their use is almost prohibited to all but the wealthy.

For cooking in hot weather, and for small flats, they are a great boon, because the gas can be turned out or lowered, as desired, and much unnecessary heat saved.

Unfortunately, householders complain of the careless waste of gas caused by the burners being left full on when not needed, or the stove being used when, perhaps, there is already a large coal fire burning in the kitchen.

Besides this trouble, there is not infrequently an objectionable odour in houses where the cooking is done by gas, so much so, that on entering the front door, it is easily noticeable that the stove is lit. The reason for this is either:

1. The dirty condition of the top of the stove under the boiling rings, and the interior of the oven.

2. Too great a pressure of gas being turned on for the size of the stove.

3. The stove being "lit back," as people express it—that is, the draught causing it to light in the air chamber of the burner. This may be known by the peculiar noise made, and the flame will be of a yellow, instead of a blue colour. It also causes a most unpleasant smell, and soon the burners become choked with soot, and very little heat is given. When this occurs, the gas must be turned out and lit again, and even several times, if necessary, till it lights properly. To prevent it, the gas should be turned on for a second or two before the match is applied.

If possible, choose a stove lined throughout with enamel, and the rests for the shelves made to pull out. This kind is so easy to clean, and the bright lining reflects the heat and aids the cooking operations.

The stove should also be provided with a good griller or toaster, the heat from the burner, by a simple contrivance, being thrown downwards on to the bread, or whatever it may be.

To Clean Gas Stoves. Remove all parts possible—bars, shelves, etc. Wash the top or any greasy part thoroughly with hot soda water.

Blacklead and polish all the black portions. Clean the bars with emery paper, and any brass fittings with bathbrick dust and a leather, or soft cloth. Should there be any tiles on the stove, wash them with hot water, soda, and a piece of house flannel.

Carefully note that the holes of the burners are not choked with grease from pans boiling over. This point is very frequently forgotten, with the result that a very small jet of flame is obtained.

Substitutes for Weights and Scales. Though most convenient, weights and scales are not an essential item in the kitchen, and in very many households they are conspicuous by their absence. But it is unwise to trust merely to guessing the quantities; and the following table will be helpful, giving, as it does, equivalents for the usual weights:

1 heaped tablespoonful of flour .. .	1 ounce
1 tablespoonful of moist sugar	1 ounce
Half a tablespoonful of syrup, jam, etc. =	1 ounce
1 tablespoonful or two dessertspoonfuls of liquid .. .. =	1 ounce
4 teaspoonfuls of liquid . .. .. =	1 ounce
1 breakfast-cupful =	half a pint or half a pound
1 teacupful = ¼ of a pint .. .. .. =	¼ pound
6 lumps of sugar .. .. =	1 ounce
A piece of suet, butter, lard, or clarified fat, the size of a small hen's egg =	1 ounce
Weight of an average-sized egg	2 ounces
Half a candied lemon or orange .. .. =	1 ounce

Testing the Oven. It is well to test the heat of the oven before putting in the meat, tart, or whatever it is. To do this, place a piece of white paper on the shelf, and leave it for five minutes. If it has turned

Light yellow, the oven is "slow"
Dark yellow „ „ "moderate"
Dark brown „ „ "quick"
Black „ „ "too hot"

A MARKETING GUIDE

When at all possible, every housekeeper should do her own marketing; she will then be able to study the prices of the various things, and avoid those articles which, owing to various reasons—such as the demand for them, or the weather—are high in price on that particular day; while, at the same time, she may sometimes be able to give her family delicacies which, as a rule, she would consider beyond her means.

However slender the family purse is, it is bad policy to purchase inferior goods; stale fruit, withered vegetables, and stale fish are highly injurious.

Meat

When choosing meat, it is well to remember that a joint containing much fat or bone is not economical. Also, that young meat, such as veal and lamb, contains less nutriment than the flesh of mature animals, such as mutton.

Beef. Good beef should be of a fine, even grain, veined with fat, which should be firm and of a creamy dull white. The lean should be a purplish red. Scotch beef is considered the best.

Mutton. Good mutton should have small bones; the lean should be of a dark red, and the fat hard and white. If the flesh is flabby and damp, it is inferior.

Veal. Veal should have a fine grain, with the fat very white. If it is very young meat, it contains little nourishment, and it is considered by many to be indigestible.

Pork. Pork should never be purchased in hot weather, but is excellent during the winter months. The lean should be of a delicate, pinkish white, with the grain fine and close, and the bones small.

Bacon. Bacon with the lean of a very deep red is usually very hard and salty. The fat should be of a pinkish white, and the lean free from cracks.

Fish

When choosing fish, see that the eyes are bright and the gills a clear bright red; the body should feel stiff and the flesh firm. Very large fish of their kind should be avoided—they are usually old and stringy. It is absolutely essential that shellfish be perfectly fresh, otherwise it is most unwholesome; if in good condition, it should feel heavy in comparison to its size—a light lobster is always watery. If a lobster, crab, prawn, or shrimp is fresh, the tail is drawn tightly against the body; pull back the tail, and it will immediately spring again to its place. An oyster-shell will be firmly closed if it is fresh; if it gapes a little, the oyster is losing its freshness.

Poultry

When choosing poultry, see that the eyes are clear. The bird should be plump, without being over fat, the legs smooth and supple, and the feet large for the size of the bird. The skin should be free from hair, these denoting age. Hen birds are considered more tender than cocks, and those having yellow legs are generally preferred for boiling.

Choose ducks and geese with yellow legs; those with deep orange coloured legs are usually ancient birds.

Select rabbits with soft brown fur and large joints—these are the signs of youth; old ones have greyish fur and rather blunt claws.

Game

For roasting, choose young birds; but for salmis, stews, and soups, old ones will do excellently. As a rule, hen birds are considered more tender and juicy than cock birds. If young, the quills will be soft, and in the cock bird the spurs short and smooth. The under part of the beak will snap across if it is bent back, and the legs will be smooth and supple.

Venison is not considered worth eating unless it has plenty of clear, bright-looking fat.

The legs of wild duck, teal, and widgeon should be soft and pliable.

Young hares should have smooth, sharp claws, thin ears which can be easily torn, and large knee joints. They should be chosen for roasting purposes, though old ones do very well for jugging.

Vegetables

On no account purchase stale vegetables; they are most unwholesome. Cabbages which are limp, battered about, and turning yellow should be avoided, also withered lettuces and cress. It is poor economy to purchase cheapened goods when half of them is useless; it is far better to get half the quantity for the same money. This is particularly so in the case of green peas. It is more economical to purchase half a peck at one shilling a peck than one peck at sixpence. In the latter case, the pods would probably be yellow and withered, and the peas dry and hard, consequently taking a long time and much fuel to soften them; while in the former, they are fresh, green, and soon cooked.

If at all possible, buy potatoes in large quantities, and store them in a dry, dark place for winter. A rough-skinned potato is generally floury, but there are some exceptions to this rule. Small potatoes are not economical, even if low in price, as so much of them is wasted in peeling.

Fruit

Like vegetables, fruit must be fresh and in good condition, otherwise it is best avoided. Wellington apples are the best variety for baking in tarts or mincemeat.

Dry Stores

If buying flour for ordinary use, "households" or "seconds" is the best, while "Vienna," or pastry "whites" is best for cakes, puff pastry, etc.

As coffee, oatmeal, and all spices deteriorate with keeping, they are best purchased as required, in small quantities.

Rice, sago, sugar, etc., may be bought in large quantities, provided they are kept in covered jars away from the dust.

Household soap should be purchased in large quantities, as it dries with keeping, and so is much more economical.

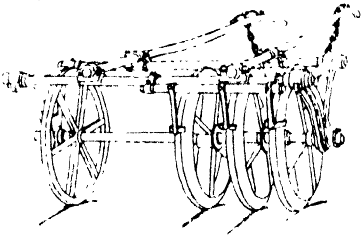
CULTIVATION OF LAND FOR CEREALS

Ploughing, Harrowing and Sowing for Wheat, Barley, Oats, and Root Crops. Mangels and Weeds. Time for Drilling Seeds. Catch Crops

By Professor JAMES LONG

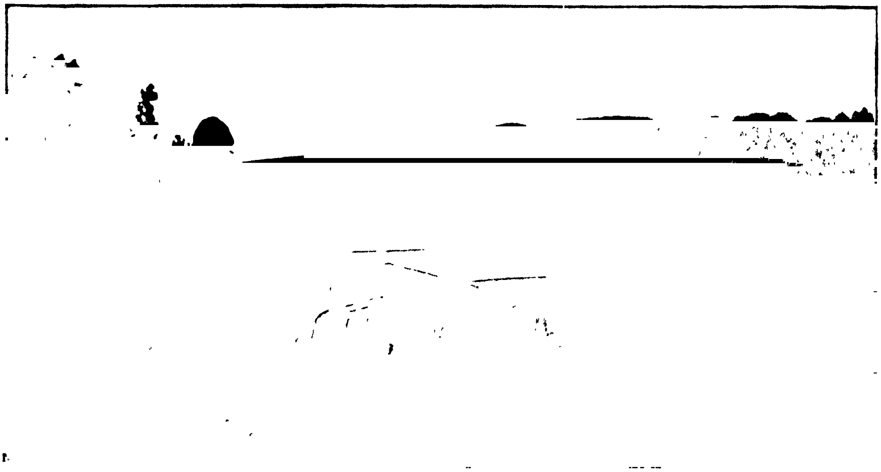
WHEAT is usually sown on land which has been dunged and which belongs to the heavier class of soil. The land is ploughed early, harrowed, and the seed drilled. In some of the lighter land districts where wheat is grown the soil is ploughed rather shallow, furrows are made with a ring-presser to provide a firm bed, and the seed is broadcasted and covered with the harrows. Heavy land often needs weathering after ploughing before harrowing is possible, by which we mean that the sticky, clay-like soil turned over by the plough must be brought to such a condition by the aid of wind, rain, sun, or frost, that it will break to pieces when the harrows are drawn over it. As wheat needs a firm bed, care must be taken not to plough too deeply, nor to make the soil too loose. Wheat being an autumn-sown plant, it is often essential to make water-furrows to prevent rain-water collecting and thus destroying it.



RING-PRESSER

Barley. The object of the barley grower is not only to obtain a large yield, but fine samples for malting purposes. In spite of foreign competition and the employment of barley-malt substitutes, a good sample will still realise a respectable price; but a sample which is unfit for malting falls to a low figure, owing to the much smaller value of this cereal for feeding purposes. Quality depends upon the soil, the season—especially during ripening and harvesting—and the method of cultivation. In the most suitable districts the barley crop is a profitable one, but in unsuitable districts, and largely on heavy soils, it is much more difficult to obtain quality. Barley is very commonly taken after a root crop fed off by sheep, for the reason that it thrives upon the enriched shallow surface soil, upon which the flock has been folded to eat off swedes, turnips, sainfoin, rape, kale, and other plants provided for them. It is, however, a recognised principle that a field intended for barley should never be too rich, or a sample may be spoiled. When, therefore, its condition is higher than is desirable, oats or wheat may be taken before the barley. Barley is also taken after a potato crop, this tuber, being a gross feeder, seldom leaving too large a residue of plant food, unless it has been heavily manured.

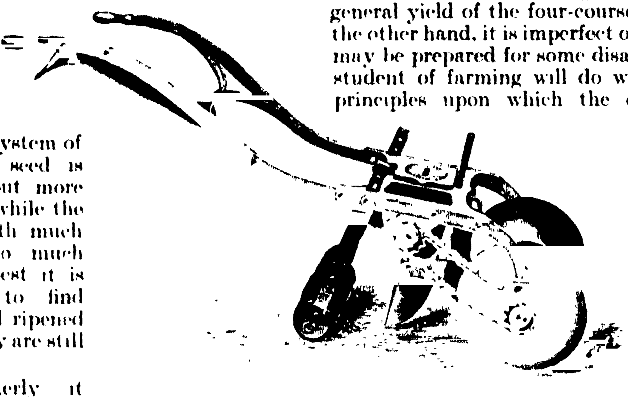
It is most essential that barley should be sown in a very fine seed-bed, and this is another reason why it should follow a root crop, for, in preparing for roots by several cultivations, the tilth is made both deep and mellow. In such a case the land needs but a shallow ploughing, the object being to provide fineness above and firmness below, and yet the soil must be dry. The seed-bed must be prepared in dry weather by using the most appropriate tools, as the



PLOUGHING: BREAKING UP A NEW FIELD

curved tined or drag harrow, the medium spiked harrow, and the roller. Above all, poaching must be avoided, especially where the soil runs together and becomes impossible of cultivation when trodden upon by either men or horses. In order to obtain evenness of growth the seed should be drilled, that it may be deposited at an equal depth ; covering may be completed with light harrows, that the soil above the seed may remain in a kind and mellow condition.

Oats. Oats are sown in two seasons, although the winter oat, which is drilled in early autumn, is common to but few districts. The grain of the winter variety is preferred by many owners of horses, especially of hunters, while the straw is much superior in strength and form to that of the spring oat, which is usually sown between the end of January and early April. When the weather is open, the earlier the sowing the better. The seed-bed may be deeper than for barley, but it is not necessary to produce so fine a tilth, the oat being a vigorous growing plant, and thriving on almost all classes of soil which are sufficiently provided with food, and which are clean and dry. The system of broadcasting the seed is quite common, but more seed is required, while the plants appear with much less regularity, so much so that at harvest it is not uncommon to find the majority well ripened while the minority are still almost green



MANGEL DRILL

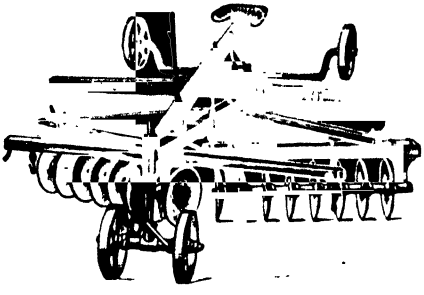
Peas. Formerly it was the more general practice to sow the earliest peas in autumn, but in these days farmers prefer early spring. The pea demands a tolerably fine seed-bed, for which reason the land should be ploughed as soon as possible after the previous crop has been removed. The first drilling may be in January, if the weather permits, the blue flowered varieties being selected, further sowing following from time to time until the middle of March. As the season advances, the later varieties are sown. Land intended for peas should not be touched during wet weather, for, where poaching follows the treading of horses and men, success is impossible. Care must be taken to guard against the depredation of birds, especially of the wood-pigeon, which quickly finds and steals the seed.

Beans. Beans are commonly taken after wheat on strong land, and are sown early in the year, what are known as winter beans being first selected, the spring varieties following in due course. The bean stands moderately severe weather without harm on dry or well-drained land. It requires a fairly deep seed-bed, which need not be exceptionally fine in tilth. The land should be ploughed in autumn, that its condition may become sufficiently mellow, and a suitable day being selected, it may be harrowed down and drilled at once. When drilling is impossible, the method of dibbling may be resorted to, for it occasionally happens that sowing would otherwise be much delayed owing to the impossibility of taking the horses on to the land without damage. In dibbling, holes are made with a hand-tool, and the seed deposited in rows at equal distances apart. Before the bean plant appears, harrows may be drawn over the field with the object of killing weeds which may have begun to grow ; when the rows are sufficiently defined, the horse-hoe may be employed with the same object. Land intended for beans is occasionally manured with dung, covered in by the plough in autumn.

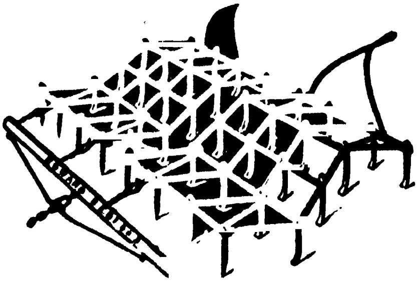
Roots. By the preparation of the soil for the root crops, by which we mean mangels, rabi, swedes, and turnips, although potatoes may be appropriately included, the whole rotation is affected. If the work is good, it tells upon the general yield of the four-course rotation ; if, on the other hand, it is imperfect or bad, the farmer may be prepared for some disappointment. The student of farming will do well to master the principles upon which the cultivation of the soil is founded in relation to fallow land.

It may here be remarked that there are two classes of fallow, the one applied to land which carries fallow crops, among which roots are included ; the other, known as bare fallow, chiefly applied to very heavy land. The object of bare fallowing was formerly intended to provide the soil with a rest, and to give it time to accumulate fertility before it was asked to produce another crop. In these days bare fallowing is chiefly resorted to for the purpose of cleaning land, ploughing being conducted from time to time during the hot weather of summer, when, by the aid of the sun, weed-life is destroyed. The more this subject is studied by the student the more clearly it will be shown, however, that, unless in exceptional cases, a bare fallow is a waste. If it is regarded as impossible to grow a saleable crop with profit, it is preferable to sow for a green crop, which may be ploughed in as green manure, and in this way to prepare a field for a profitable succession.

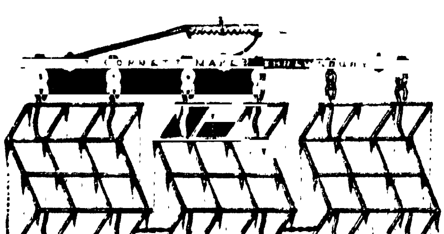
Elements of a Successful Root Crop. A successful root crop largely depends upon early autumn ploughing. The land intended to carry mangels should first be tackled, if possible immediately after harvest. If time permits, it may be skimmed 2 to 3 in. deep with the broad share, which not only accomplishes quick work, but destroys growing weeds, and induces weed seed to sprout ready for subsequent burying with the plough. In this work the sun may possibly be an available helper. Subsequent work with the harrows will largely remove such obnoxious weeds as twitch or couch-grass before the plough starts its work. In some cases, especially on light soils, the steam cultivator is introduced, and the land is twice stirred, one cultivation crossing the other. Such practice makes it easier for the horses when ploughing begins. On the heavier soils, which have been similarly prepared and harrowed, the soil being dry, the land may be ploughed to a depth of 6 to 7 in. If this is permissible, as it should be for the mangel, which flourishes best on deep, strong, rich loams, the soil may be subsequently ploughed with the ridging plough, and left rough through the winter. By this means the clods will be pulverised by frost, the soil forming the ridges will remain fairly dry, while the rain-water will find its way into the furrows between.



THE DISC HARROW



DRAG HARROW



A SET OF HARROWS

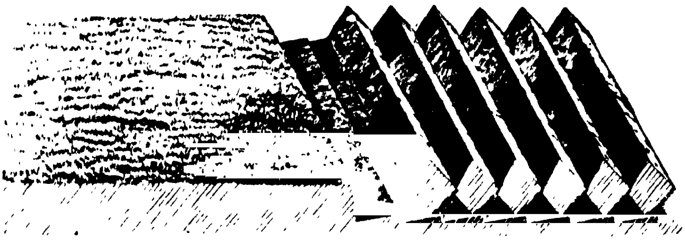
Autumn Ploughing. So much depending upon autumn cultivation for roots, the necessity of early sowing and harvesting will be recognised. But it must not be supposed that early autumn ploughing is essential for roots alone. The land may be prepared for wheat and beans, oats and barley, where it is intended that the seed for these crops should be sown early. Land should not be touched with plough, harrow or roller while it is wet, although there are some of the lighter soils upon which work may proceed very quickly after heavy rain, and here experience, which begets judgment, will stand the student in good stead. Roots not only demand a fine and deep tilth, for which reason a fine surface tilth should not be buried, but they demand sufficient moisture near the surface to encourage the early germination of the seed. How important this point is will be noticed if the thick, hard husk in which the seed of the mangel is enveloped is examined.

Drilling of Mangels and Turnips. Both mangels and turnips are drilled upon the ridge on the heavier soils ; the whole of the soil forming the ridge should, therefore, be fine. Before ridging for the drill with the double-breasted plough—this being the final operation with this tool—root land is usually spring ploughed once or twice, according to its condition. When this is sufficiently perfect, the ridges are drawn, usually 27 in. apart, and the furrows between manured with rotten dung, and where mineral fertilisers are employed, with these also. The plough then passes through the middle of each ridge, splitting it in halves, covering the manure, and at the same time forming fresh ridges. These are subsequently pressed with a light roller —for it is essential to prevent the soil "running" or sticking together by extreme pressure—and on the flat surface thus produced the seed is drilled. Swedes and turnips germinate better when drilled quickly after this operation and while the land is still moist. Swedes are sown between the middle of May and the beginning of July, depending upon the district and climate, the dates of sowing being earlier in the south than in the north. Turnips are sown during June and the first half of July, while stubble turnips, frequently broadcasted, are sown between the middle of July and the last week in August.

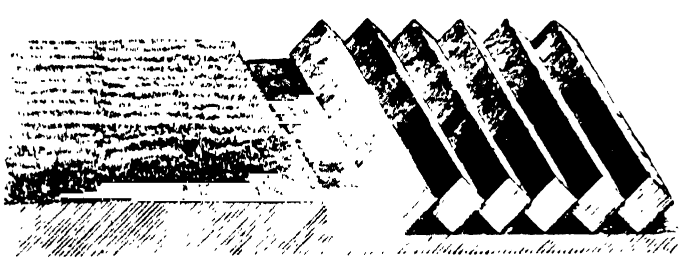
The student will do well to notice the difference in the rapidity of the germination of turnip seed on a coarse or dry tilth and on a fine, moist, fresh tilth, which has been lightly rolled. The mangel, owing to its preference for stronger soil, is generally sown on the ridge, with manure beneath ; while the swede, although the same system of manuring is sometimes followed, is more commonly manured with phosphatic manures alone.

It is important that in all cases the ridges upon which roots are grown should not be less than 27 in. apart in order that the horse-hoe may be more easily and advantageously employed in keeping spaces between each row of plants perfectly clean. The mangel plants, which, with successful germination, produce almost unbroken rows, are subsequently singled with the hand-hoe, each bulb being left from 9 to 15 in. from its neighbours. The wider the bulbs are apart the larger they grow, but while medium bulbs involve more labour in lifting at harvest, they are richer as a food. Mangels are frequently grown on the flat on the lighter soils, for the reason that they better obtain the necessary supply of moisture.

Mangels and Weeds. Owing, however, to the fact that weeds grow more quickly than the mangel plant, it is good practice to mix with the mangel seed in the drill a small quantity of turnip seed, which appears earlier than the mangel plant; then the rows may be seen sufficiently early to introduce the horse hoe before the weeds have taken absolute possession of the soil. The mangel is sown between the end of March and the middle of May, and the variety selected will depend upon the experience of the grower. Some find the Globe or Tankard superior to the Long Red, which is more difficult to lift owing to the fact that a larger proportion of the root grows within the soil. For this reason it frequently breaks off in pulling, involving extra labour or loss. The object of the grower, however, should be not only to obtain weight per acre, but weight of food per acre, and this he will secure by selecting varieties which are known to contain a high proportion of feeding matter and to grow them closer together in the rows than usual.



CRESTED FURROW SLICE



RECTANGULAR FURROW SLICE

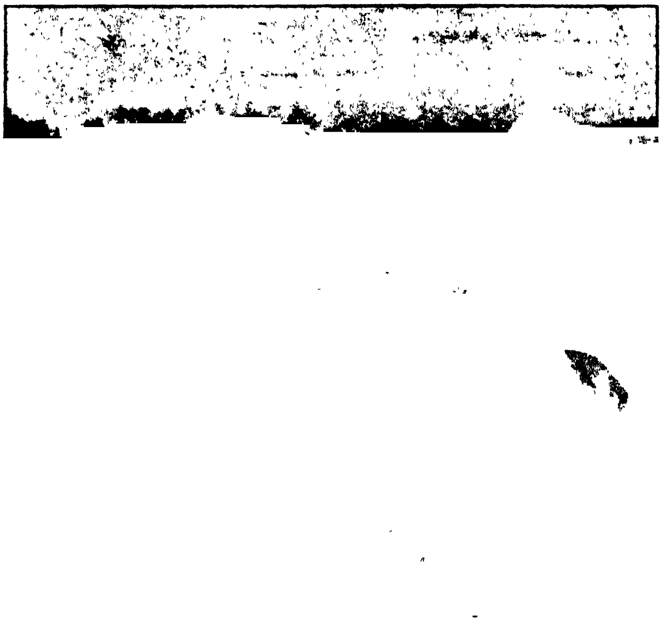
FURROW SLICE BROKEN UP

METHODS OF PLOUGHING

Where blanks occur in a mangel field they may be filled up by planting cabbage or kohl-rabi, unless swede seed, having been sown with the mangel seed, plants of this root are in possession. Whether the mangel land has been supplied with dung, after ploughing in autumn, or under the seed in spring, it may be advantageously dressed with nitrate of soda during its early growth. This fertiliser may be supplied at the rate of ½ to ¾ cwt. per acre when the young plants have been a fortnight above ground, while a second and similar dressing may be provided when they are half grown.

Clovers and Seeds. Clover is usually sown alone, a common practice with the broad red and crimson varieties, to which reference has been made; but under varied conditions, depending upon the purpose for which the crop is required, and upon some soils, the character of which must always be consulted, mixtures are sometimes preferred. These mixtures may consist of the clovers proper—broad red, cow-grass, alsike, and white, or one or more of these varieties added to Italian rye grass, or, where the plant is to remain on the ground for two years or more, yet temporarily, with the addition of cocksfoot, catstail, and occasionally lucerne and smooth and rough-stalked meadow-grass, as shown in the chapter on grasses. Temporary mixtures are usually known as "seeds," or "leys," and the seeds are sown with a corn crop.

Clover is usually drilled, especially where it is grown with wheat, but the seed should not be deposited more than half an inch in depth. Where, as should be the case, the soil covers the seed after the drill, it may be found sufficient to roll it, otherwise, as where it is broadcasted with the seed-barrow, it should be covered with light harrows, and subsequently rolled. In some instances it is sufficient to cover with a bush-harrow, skilfully made by fixing a number of strong blackthorn boughs to a hurdle or an implement equally convenient. Again, some farmers find it satisfactory to cover the seed with a horse-rake, but in all cases rolling, the weight of the roller depending upon the class and condition of the soil, should follow. The farmer, too, must judge whether he should sow his mixture of seeds at one or two operations. The seed-barrow is of great width, and takes a long sweep, but, careful as the workman may be, he frequently misses the line of seeding, with the result that when the plant appears many places are recognised which were never seeded at all. This is prevented by dividing the seed into two portions, and sowing the second portion across the first. In using the seed-barrow it may constantly happen, too, unless care is exercised, that the small, heavy clover seeds remain at the bottom of the box, and are not equally scattered with the grass seeds by the brushes within.



CARTING MANGELS

Sutton

Time for Drilling Seed. Occasionally seed is drilled with spring corn, but on soils where the tilth is fine and deep, this is liable to bury the fine clover and grass seeds, which prefer a shallow, firm bed. The more general practice is to wait until the oats or barley have appeared, and are sufficiently strong to permit of the drill being used, or for the operation as conducted with the seed-barrow. Both sainfoin and lucerne, which may be regarded as seeds, are similarly drilled with, or among growing corn, but in no case is the crop obtained in the same year, although, where the growth is precocious, there may be sufficient green food cut when the corn is harvested to improve the value of the straw. The cropping of clover, sainfoin, and lucerne assists in renewing the fertility of the soil, but it is inadvisable to allow either plant to remain down long enough to become so foul that the land is in part impoverished by weeds, or rendered difficult to clean and cultivate for a succeeding crop.

In some cases, where the soil is foul, beans may replace clover in the rotation, for the reason that the land, as already explained, can be horse-hoed between the rows forming the crop. Land intended for seeds should always be well supplied with lime, which may sometimes save a plant from the ravages of the eel-worm, the chief enemy of broad clover. With this object half a ton of ground lime, preferably produced from chalk, may be sown per acre.

Forage, or Catch Crops. A "catch" crop is a crop which is taken between two regular or rotation crops, as crimson clover sown upon wheat stubble, and removed sufficiently early in spring for turnips to be sown. These crops include crimson clover, vetches or tares, rye, winter barley and oats, all of which should be sown early in the autumn, that they may be cut green and removed early in spring. Before sowing it is advisable that the land should be well cleaned by surface-harrowing for the destruction of growing weeds, and to incite the germination of weed seeds. The land, except for trifolium (crimson clover), which is sown upon the harrowed stubble, should be shallow ploughed, and the seed drilled and harrowed in while the surface is dry and kind. Where, however, time permits, deep ploughing is advisable, inasmuch as it will materially help a succeeding root crop. Catch crops are always assisted by the provision of a dressing of artificial manure where the soil is not in the best of condition. But for trifolium and vetches phosphatic manures are recommended, and for the cereals a combination, not a mixture, of phosphatic and nitrogenous manure (sulphate of ammonia),

SHORTHAND

Ninth Instalment of the Special Course of Shorthand Taught by Messrs. Pitman & Sons on their Twentieth Century Plan

By SIR ISAAC PITMAN & SONS

THE student has in the preceding lessons mastered a number of grammalogues, that is, words in common use which are represented by abbreviated phonographic signs. In the following list these are included, while many additional grammalogues are given, and the table should be studied and mastered in accordance with the instructions given on the next page.

Grammalogues (Phonetically Arranged). Grammalogues marked "1" (first position) are written *above* the line. Those marked "3" (third position) are written *through* the line. Those not marked (second position) are written *on* the line

CONSONANTS.

ai	ay, aye (broad ai, yes)
ow	how
wi	why

By means of the directions furnished below, the table on the preceding page may be readily committed to memory. Alphabetic characters are used to represent all the grammalogues except *and*, *he*, and *therefore*, for which convenient signs are allocated.

The POSITIONS of the logograms, ABOVE, ON, and THROUGH the line, are in general determined by the vowels contained in the words; and if a word has more than one syllable, by its accented vowel. For perpendicular and sloping strokes, standing alone, the positions are

1 *ah, aw, ă, ŏ, ī, oi, wī,* ABOVE the line ; thus *at*.

2 *eh, oh, ĕ, ŭ,* ON the line ; thus *up*, *whether*.

3 *ee, oo, ĭ, ŏŏ, ow, ū,* THROUGH the line ; thus *each*.

Vowel logograms, and horizontal and half-sized consonants, have but TWO positions

1 *ah, aw, ă, ŏ, ī, oi, ay, wī,* ABOVE the line ; as *ah*.

2 *eh, oh, ĕ, ŭ, ee, oo, ĭ, ŏŏ, ū, ow,* ON the line ; as *too*.

These rules do not apply to the irregular grammalogues set out below.

It will be noticed that in the table of grammalogues some words are indicated with a hyphen (as, *give-n*) ; or, with a double termination (as, *importan^t_ce*). The corresponding logograms represent both *give* and *given*, *important* and *importance*.

In order to mark the plural number, the possessive case of a noun, or the third person singular of a verb, s may be added to a logogram ; thus

good, goods ; God, Gods ; come, comes.

A logogram may be used either as a prefix or suffix ; thus

afternoon, undertake, hereafter, indifferent

Irregular grammalogues are of two descriptions, namely

1 Those of frequent occurrence, written ON THE LINE for convenience. These are

EXERCISE.

Introducing the grammalogues in the preceding table. To be written in shorthand by the student, who must use the grammalogue sign for every word.

1. My dear C.,—One without principle we cannot ever call a gentleman. 2. If he has no pleasure in the good nor in the true, we do not think of his nature as great. 3. We can, however, remark that Lord W., General L., and Mr. N., are numbered as gentlemen. 4. Though there has been no particular opportunity, these have each and all had an eye to and improved on any important advantage, and been the first to give a good account of it. 5. We thank them, and remember those things, therefore, because we know them to-be not a delivery of mere words. 6. Oh! that all would do this, whether in their opinion or not there was equal advantage or no. 7. Ah! how different might things be ; what differences could be quite put out by a more happy spirit, and through the use of words or language which should give no care. 8. Why, if we have the will to deliver it, in the awe of God, this may yet be so! 9. Aye, of a truth, he himself is of this opinion ; for myself, I shall use this very language with your doctor. 10. As usual, I shall put down every word delivered in Phonography, which is of great use in my hand. 11. It is quite usual, too, for me to see not several but a very large number of those who use it, and whose principal pleasure it is to do all toward the improvement of others in it when near them, according to their opportunity. 12. It should be remembered that much was done during the first year, ay and beyond, for it is over two years ago that he told you to come or go to them when you had any difficult thing. 13. Under them our members, in a short while, I think, after the above, will equally improve much. 14. I know all will go up with us to thank him, at or from whose hands has principally been given so much, and therefore it is of importance that he should be called upon and thanked.

Writing in Position. When writing very rapidly it is impossible to insert many vowels. This has been recognised throughout, and the rules of the system have been formulated, as far as possible, with a view to the *indication* of the vowels when they are omitted. Thus, for example, it is provided that where there is an initial vowel there must be an initial stroke consonant, as in the words *ask*, *espy*,

assail, etc. And, in the same way, where there is a final vowel there must also be a final stroke consonant, as in the words *racy*, *money*, etc. In these and similar words the presence of an initial or final vowel is *indicated* by the outline of the word, without actually writing the vowel sign. Further instances of a like nature will readily occur to the student, in connection with the rules for the writing of upward and downward *l* and *r*.

In addition to the foregoing methods of vowel signification, there is the writing of consonantal outlines in *position*, by which it is possible to indicate the vowel or the principal vowel in a word. As there are three positions in which to place the vowels when inserted, so there are three positions in which to place the consonantal outlines when the vowels are omitted. The positions are named respectively *first position*, *second position*, and *third position;* the first being *above* the line, the second *on* the line, and the third *through* the line; thus 1, 2, 3,

When the vowel or principal vowel in a word is a *first-place* vowel, the outline for the word is written in the *first position*, above the line; thus *gaudy*, *dock*, *daughter*, *carry*, *laugh*.

When the vowel or principal vowel in a word is a *second-place* vowel, the outline for the word is written in the *second position*, on the line; thus *code*, *fairy*, *debtor*, *loaf*.

When the vowel or principal vowel in a word is a *third-place* vowel, the outline for the word is written in the *third position*, through the line; thus *keyed*, *fury*, *feeder*, *curious*, *leaf*.

In words consisting of a horizontal letter preceded or followed by an upright or sloping letter, the latter determines the position of the outline, the horizontal letter being raised or lowered as required; thus *pack*, *peck*, *pick*; *cap*, *cape*, *keep*. Derivative words should commence in the same position as the primary word; thus *care*, *careful*, *anyone*, *anybody*, *anywhere*, *no one*, *nobody*, *nowhere*.

There is no *third position* for words whose outlines consist of horizontal letters only, or of half-sized letters only, or of horizontal letters joined to half-sized letters. When the vowel or principal vowel in such words is a third-place vowel, the outline is written in the *second position*, on the line; thus *sank*, *sunk*, *sink*; *standing*, *tendered*, *splintered*, *gallant*, *colt*, *kilt*; *matted*, *mated*, *meted*.

Words in which the diphthong *i* is accented are written in the *first position;* as *higher*, *guidance*. Where the diphthong *ow* is accented, the outline of the word is written in the *third position;* as *prowl*.

Double-length PERPENDICULAR strokes and straight SLOPING downstrokes take only the third position, THROUGH the line; as *ponder*, *plunder*, *pounder*, *tender*, *asunder*. A double-length CURVED sloping stroke, or a straight upstroke, can be written in the three positions; as *father*, *fetter*, *future*, *latter*, *letter*, *litter*; *wander*, *wonder*, *winter*.

In words which begin with a *first-place* vowel, the insertion of the initial vowel will usually afford the greatest facility in reading. But the initial vowel need not be written in words like *arise*, *orderly*, *ask*, where it is indicated by the first consonant. It should, however, be written in such words as *apposite* (to distinguish the outline from *opposite*), *address* (to distinguish it from *dress*), *administration* (to distinguish it from *demonstration*). It is sometimes necessary also, for the sake of distinction, to insert a final vowel in words where the vowel cannot be indicated by the form of the last consonant; as *lady* (to distinguish from *load*), *monarchy* (to distinguish from *monarch*), *enemy* (to distinguish from *name*), *extricate* (to distinguish from *extract*). The student will meet with other instances where there is a liability of clashing unless a vowel is inserted. Experience only will guide him in this matter, but he should rather vocalize more freely than necessary than run the risk of illegibility.

The rules as to position are not applicable to such words as have *outlines of their own*, (which are readily recognised by their distinctive form), because the inconvenience of writing words like *dogmatic*, *Trafalgar*, etc., in the first position, and *discipline*, *Peterborough*, etc., in the third position, in accordance with their accented vowels, would not be compensated by greater ease in reading.

In the final instalment further instruction will be given, which will enable the student to read and write the Reporting Style employed in note-taking of various descriptions.

PARLIAMENTARY POWERS

Regulations and Practice in Obtaining Parliamentary Powers for Railways, Tramways, Canals, Bridges and Other Works

Group 11
CIVIL ENGINEERING
9

Continued from page 1148

By A. TAYLOR ALLEN

Parliamentary Work. Parliamentary work consists of the preparation of plans and sections for projected schemes before Parliament having reference to railways, canals, harbours, docks, waterworks, gas, tramway, and other kinds of engineering schemes.

The plan and sections should agree from actual measurements on the ground, the one being co-existent with the other, the fences and other objects being properly delineated in their lateral position, so that the engineer for the scheme, on the appearance of the petitions and subsequent efforts, may sustain the allegations against his work by the opponents to the Bill, and that his plans may successfully pass upon Standing Orders.

Parliamentary work is very rarely accomplished without the surveyor and his staff having, in some shape or form, to trespass upon the property of others, and it should be kept clearly in mind that, under such circumstances, it is essential to fulfil one's duties with as little chance of offending the owner or occupier as possible, and most assuredly to avoid doing any damage.

Qualities in the Surveyor. By courtesy and consideration in field work, the surveyor will enhance his position and command the respect of a landowner, whom, at a future date, he may meet either as a promoter or objector of the projected scheme. He must be qualified to act as witness, arbitrator, or umpire—three qualifications which demand the most careful training. As a witness, he must have clear opinions and clear reasons for holding them, and these opinions he must be able to express in concise and lucid language. As an arbitrator, he should have the qualities of an advocate, discriminating those points most favourable to his own case and lucidly enforcing them. As an umpire, he shall have the qualities of a judge, skill and judgment in weighing evidence on both sides, and in selecting only the material points.

Projected Schemes. The regulations regarding the preparation and deposit of plans and sections for projected schemes are best explained by giving extracts from the Standing Orders of the Houses of Parliament affecting private Bills:

In cases of Bills of the second class a plan and also a duplicate thereof, together with a book of reference thereto, and a section and also a duplicate thereof, as hereinafter described, and in cases of Bills of the first class, under the powers of which any lands or houses may be taken or used compulsorily, and in the case of all Bills, by which any charge is imposed upon any lands or houses, or any lands or houses are rendered liable to have a charge imposed upon them in respect of any improvement, a plan and duplicate thereof, together with a book of reference thereto, shall be deposited for public inspection at the office of the clerk of the peace for every county, riding, or division in England or Ireland, or in the office of the principal sheriff clerk of every county in Scotland, and where any county in Scotland is divided into districts or divisions, then also in the office of the principal sheriff clerk, in or for each district or division, in or through which the work is proposed to be made, maintained, varied, extended, or enlarged, or in which such lands or houses are situate, on or before November 30th immediately preceding the application for the Bill; and in the case of railway Bills, the Ordnance map on the scale of 1 in. to a mile, with the line of railway delineated thereon, so as to show its general course and direction, shall be deposited with such plans, sections, and book of reference; and the clerks of the peace or sheriff clerks, or their respective deputies, shall make a memorial in writing upon the plans, sections, and books of reference so deposited with them denoting the time at which the same were lodged in their respective offices, and shall at all reasonable hours of the day permit any person to view and examine one of the same, and to make copies or extracts therefrom; and *one* of the two plans and sections so deposited shall be sealed up and retained in the possession of the clerk of the peace or sheriff clerk until called for by order of one of the two Houses of Parliament. In cases of Bills whereby it is proposed to alter or extend the municipal boundary of any city, borough, or urban district, a map on a scale of not less than 3 in. to a mile, and also a duplicate thereof, showing as well the present boundaries of the city, borough, or urban district as the boundaries of the proposed extension, shall be deposited with the town-clerk of such city or borough, or clerk of such urban district, who shall at all reasonable hours of the day permit any person to view and examine such map, and to make copies thereof; and a copy of the said map, with the said boundaries delineated thereon, shall also be deposited at the office of the Board of Agriculture and Fisheries.

On or before November 30th a copy of the said plans, sections, and books of reference, and in the case of railway Bills, also a copy of the Ordnance map, with the line of railway delineated thereon, shall be deposited in the Private Bill Office of this House.

Tramway Schemes. In the case of Bills for laying down a tramway, an Ordnance map of the district on a scale of not less than 6 in. to a mile, with the line of the proposed tramway marked thereon, and a diagram on a scale of not less than 2 in. to a mile, prepared in accordance with the specimen to be obtained at the office of the Board of Trade, must also be deposited at that office on or before November 30th.

Electric Schemes. In cases of Bills for the supply of electrical energy, an Ordnance map on a scale of not less than 1 in. to the mile, with the proposed area of supply marked thereon, shall be deposited at the office of the Board of Trade on or before November 30th.

Tidal Lands. In cases where tidal lands within the ordinary spring tides are to be acquired, or in any way affected, a copy of the plans and sections shall, on or before November 30th immediately preceding the application for the Bill, be deposited at the office of the Harbour Department, Board of Trade, marked "Tidal Waters," and on such copy all tidal waters shall be coloured blue, and if the plans include any bridge across tidal waters, the dimensions, as regards span and headway of the nearest bridges, if any, across the same tidal waters above and below the proposed new bridge, shall be marked thereon; and in all such cases such plans and sections shall be accompanied by an Ordnance map of the country over which the works are proposed to extend, or are to be carried, with their position and extent, or route accurately laid down thereon.

Riverside Schemes. In cases where the work is to be situated on the banks, foreshore, or bed of any river, a copy of the plans and sections shall, on or before November 30th immediately preceding the application for the Bill, be deposited—

1. If the river is in England or Wales, at the office of the Board of Agriculture and Fisheries;
2. Or, if the river is in Scotland, at the office of the Secretary for Scotland;
3. Or, if the river is in Ireland, at the Irish Office, Westminster, and at the office of the Department of Agriculture and Technical Instruction for Ireland, Dublin;
4. And if the river is subject to a board of conservators, at the office also of such board.

Railway, Tramway, and Canal Bills. In the case of railway, tramway, and canal Bills, a copy of all plans, sections, and books of reference, required to be deposited in the office of any clerk of the peace or sheriff clerk, on or before November 30th immediately preceding the application for the Bill (and in the case of railway Bills also a copy of the Ordnance map, with the line of railway delineated thereon), shall on or before the same day be deposited in the office of the Board of Trade.

Local Authorities. Where, under the powers of any Bill, any work is intended to be made, maintained, varied, extended, or enlarged, or any lands or houses may be taken or used compulsorily, or an improvement charge may be imposed, a copy of so much of the said plans and sections as relates to any of the areas hereinafter mentioned, together with a copy of so much of the book of reference as relates to such area, shall, on or before November 30th, be deposited with the officer respectively hereinafter mentioned, that is to say, in the case of

(*a*) The City of London, or any borough in *England* or *Wales*, whether metropolitan or other, with the town-clerk of such city or borough;

(*b*) Any urban district in England or Wales, not being a borough, with the clerk of the district council;

(*c*) Any parish in England or Wales having a parish council, with the clerk of the parish council, or if there is no clerk, with the chairman of that coucil;

(*d*) Any parish in England or Wales comprised in a rural district, and not having a parish council, with the chairman of the parish meeting, and with the clerk of the district council;

(*e*) Any burgh in Scotland, with the town-clerk or clerk;

(*f*) Any parish in Scotland, outside a burgh, with the clerk of the parish council;

(*g*) Any urban or rural district in Ireland, with the clerk of the district council.

Deposit with State Departments. Where, by any Bill, power is sought to have any churchyard, burial-ground, or cemetery, or any part thereof, or to disturb the bodies interred therein, or where power is sought to take any common or commonable land, as the case may be, a copy of so much of the plans, sections, and books of reference required by these orders to be deposited in the Private Bill Office in respect of such Bill as relates to such churchyard, burial-ground, or cemetery, common or commonable land, shall, on or before November 30th, be deposited at the office of the Secretary of State for the Home Department, and a copy of so much of the said plans, sections, and books of reference as relates to such common or commonable land shall, on or before the said day, be deposited at the office of the Board of Agriculture and Fisheries.

Gazette Notice. Wherever any plan, sections, and books of reference, or parts thereof, are required to be deposited, a copy of the notice published in the "Gazette" of the intended application to Parliament shall be deposited therewith.

Description of Plans. Every plan required to be deposited shall be drawn to a scale of not less than 4 in. to a mile, and shall describe the lands which may be taken or used compulsorily, or on which an improvement charge may be imposed, or which are rendered liable to the imposition of an improvement charge, and in the case of Bills of the second class shall also describe the line or situation of the whole of the work (no alternative line or work being in any case permitted), and the lands in or through which it is to be made, maintained, varied, extended or enlarged, or through which any communication to or from the work may be made; and where it is the intention of the promoters to apply for powers to make any lateral deviation from the line of the proposed work.

the limits of such deviation shall be defined upon the plan, and all lands included within such limits shall be marked thereon ; and unless the whole of such plan shall be upon a scale of not less than a quarter of an inch to every 100 ft., an enlarged plan shall be added of any building, yard, courtyard, or land within the curtilage of any building, or of any ground cultivated as a garden, either in the line of the proposed work, or included within the limits of the said deviation, upon a scale of not less than a quarter of an inch to every 100 ft.

Canals, Reservoirs, and Aqueducts. In all cases where it is proposed to make, vary, extend, or enlarge any cut, canal, reservoir, aqueduct, or navigation, the plan shall describe the brooks and streams to be directly diverted into such intended cut, canal, reservoir, aqueduct, or navigation, or into any variation, extension, or enlargement thereof respectively, for supplying the same with water.

Powers for Railways. In all cases where it is proposed to make, vary, extend, or enlarge any railway, the plan shall exhibit thereon the distances in miles and furlongs from one of the termini ; and a memorandum of the radius of every curve not exceeding one mile in length shall be noted on the plan in furlongs and chains ; and where tunnelling as a substitute for open cutting is intended, the same shall be marked by a dotted line on the plan, and no work shall be shown as tunnelling in the making of which it will be necessary to cut through or remove the surface soil.

Diversion of Roads. If it be intended to divert, widen, or narrow any public carriage road, navigable river, canal, or railway, the course of such diversion, and the extent of such widening or narrowing, shall be marked upon the plan.

Railway Junctions. When a railway is intended to form a junction with an existing or authorised line of railway, the course of such existing or authorised line of railway shall be shown on the deposited plan for a distance of 800 yards on each side of the proposed junction, on the same scale as the scale of the general plan.

Street Tramway Bills. In cases of Bills for laying down a tramway, the plans shall indicate whether it is proposed to lay such tramway along the centre of any street, and if not along the centre, then on which side of, and at what distance from, an imaginary line drawn along the centre of such street, and whether or not, and if so, at what point or points it is proposed to lay such tramway, so that for a distance of 30 ft. or upwards a less space than 9 ft. 6 in., or if it is intended to run thereon carriages or trucks adapted for use upon railways, a less space than 10 ft. 6 in. shall intervene between the outside of the footpath on each side of the road, and the nearest rail of the tramway.

All lengths shall be stated on the plan and section in miles, furlongs, chains, and decimals of a chain. The distances in miles and furlongs from one of the termini of each tramway shall be marked on the plan and section. Each double portion of tramway, whether a passing-place or otherwise, shall be indicated by a double line. The total length of the road upon which each tramway is to be laid shall be stated—*i.e.*, the length of route of each tramway.

The length of each double and single portion of such tramway, and the total length of such double and single portions respectively, shall also be stated.

In the case of double lines (including passing-places) the distance between the centre lines of each line of tramway shall be marked on the plans. This distance must in all cases be sufficient to leave at least 15 in. between the sides of the widest carriages and engines, to be used on the tramways when passing one another. The gradients of the road on which each tramway is to be laid shall be marked on the section. Every crossing of a railway, tramway, river, or canal, shall be shown, specifying in the case of railways and tramways whether they are crossed over, under, or on the level.

All tidal waters shall be coloured blue.

All places where, for a distance of 30 ft. and upwards, there will be a less space than 9ft. 6 in. between the outside of the footpath, on either side of the road and the nearest rail of the tramway, shall be indicated by a thick dotted line on the plans, on the side, or sides, of the line of tramway where such narrow places occur, as well as noted on the plans, and the width of the road at those places should also be marked on the plans.

The preceding paragraph shall apply, in the case of a tramroad, wherever it is carried along a street or road.

Definition of Improvement. In the case of Bills containing power to impose on any lands or houses, or to render any lands or houses liable to the imposition of any charge in respect of any improvement, the plan shall define the improvement, and also the improvement area (being the limits within which the charge may be imposed).

Book of Reference. The Book of Reference shall contain the names of the owners, or reputed owners, lessees, or reputed lessees, and occupiers of all lands and houses, which may be taken or used compulsorily, or upon which any improvement charge is imposed, or which are rendered liable to have an improvement charge imposed upon them, and shall describe such lands and houses respectively.

Ordnance Datum and Scale. The section shall be drawn to the same horizontal scale as the plan, and to a vertical scale of not less than *one inch* to every 100 ft., and shall show the surface of the ground marked on the plan, the intended level of the proposed work, the height of every embankment, and the depth of every cutting, and a datum horizontal line, which shall be the same throughout the whole length of the work, or any branch thereof, respectively, and shall be referred to some fixed point (stated in writing on the section), near some portion of such work, and in the case of a canal, cut, navigation, public carriage road, or railway, near either of the termini. The distance of such fixed point above, or below, an Ordnance bench mark in the locality of the proposed works, and near one of the termini, and the height of such bench mark, above Ordnance datum, shall also be stated.

Improvement of Navigation. In cases of Bills for improving the navigation of any river there shall be a section which shall specify the levels of both banks of such river; and where any alteration is intended to be made therein, it shall describe the same by feet and inches, or decimal parts of a foot.

Railways. In every section of a railway, the line of the railway marked thereon shall correspond with the upper surface of the rails. Distances on the datum line shall be marked in miles and furlongs, to correspond with those on the plan; a vertical measure from the datum line to the line of the railway shall be marked in feet and inches or decimal parts of a foot at the commencement and termination of the railway, and at each change of the gradient or inclination thereof; and the proportion, or rate of inclination, between every two consecutive vertical measures shall also be marked.

Wherever the line of the railway is intended to cross any public carriage road, navigable river, canal, or railway, the height of the railway over, or depth under the surface thereof, and the height and span of every arch of all bridges and viaducts, by which the railway will be carried over the same, shall be marked in figures at every crossing thereof; and where the railway will be carried across any such public carriage road or railway, on the level thereof, such crossing shall be so described on the section; and it shall also be stated if such level will be unaltered.

If any alteration be intended in the water level of any canal, or in the level or rate of inclination of any public carriage road, or railway which will be crossed by the line of railway, then the same shall be stated on the section, and each alteration shall be numbered; and cross sections, in reference to the numbers, on a horizontal scale of not less than 1 in. to every 330 ft., and on a vertical scale of not less than 1 in. to every 40 ft., shall be added, which shall show the present surface of such road, canal, or railway, and the intended surface thereof when altered; and the greatest of the present and intended rates of inclination, of the portion of such road or railway intended to be altered, shall also be marked in figures thereon; and where any public carriage road is crossed on the level, a cross section of such road shall also be added, and all such cross sections shall extend for 200 yards on each side of the centre line of the railway.

Embankments and Cuttings. Wherever the extreme height of any embankment, or the extreme depth of any cutting, shall exceed 5 ft., the extreme height over, or depth under the surface of the ground, shall be marked in figures upon the section; and if any bridge or viaduct of more than three arches shall intervene in any embankment, or if any tunnel, height or depth shall be marked in figures on each of the parts into which such embankment or cutting shall be divided by such bridge, viaduct, or tunnel.

Tunnelling and Viaducts. Where tunnelling, as a substitute for open cutting, or a viaduct, as a substitute for solid embankment, is intended, the same shall be marked on the section, and no work shall be shown as tunnelling in the making of which it will be necessary to cut through or remove the surface soil.

Gradient in Case of Junctions. When a railway is intended to form a junction with an existing, or authorised, line of railway, the gradient of such existing, or authorised, line of railway shall be shown on the deposited section, and in connection therewith, and on the same scale as the general section, for a distance of 800 yards on each side of the point of junction.

Form of Estimate. The estimate for any works proposed to be authorised by any railway, tramway, tramroad, canal, dock, or harbour bill, shall be in the following form, or as near thereto as circumstances may permit.

Estimate of the Proposed Railway.

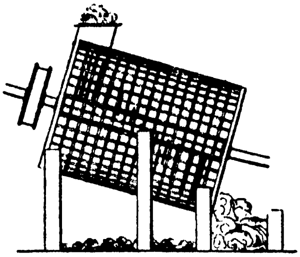
REDUCING COTTON AND WASTE SILK

The Operations of Breaking, Mixing, Opening, and Scutching Cotton. The Machines Employed. The Washing, Dressing, and Filling of Silk

By W. S. MURPHY

COTTON

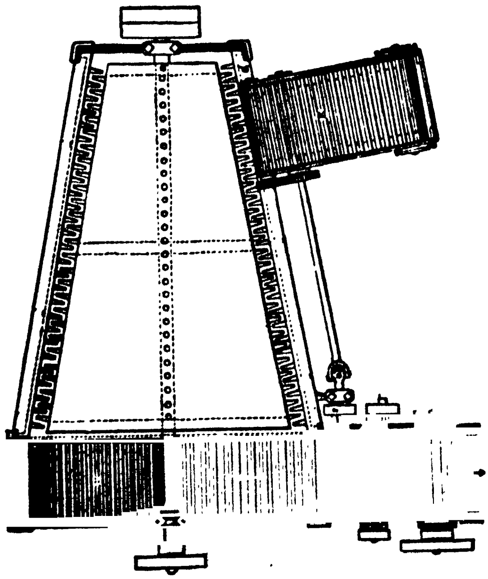
Selecting the Material. The British cotton-spinner gathers his raw material from afar, and on the cotton market the choice is wide. Here are Egyptians, brown and white; East Indian cottons ranging from medium to very coarse; New Orleans, Peruvian, West Indian, Brazilian, Sea-Island, and many other cottons, as the student already knows. The question now is, What kind of cotton do we want? Surats, Bengals, and inferior Uplands make coarse wefts; Bahia, New Orleans, Demerara, and inferior Sea-Islands form fine muslin wefts; warps are spun from Egyptians, Maranhams, Pernams, and Sea-Islands; brown Egyptian and fine Sea-Island are mixed for the finest sewing threads. The selection is varied, but the task of selecting is lightened by the fact that most manufacturers specialise in a limited range of yarns, some concentrating on fine counts, others on mediums, and a few on special classes of yarns, while the vast mass of the trade must be content with producing low counts, ranging from 10's up to 30's.



42. THE PRIMITIVE WILLOW OF NORMANDY

The best commercial results are obtained by mixing the fibres in various ranges of quality. By judicious mixing it is possible to obtain a good quality of yarn more cheaply than by using only one kind or class of cotton-wool. In the selection of cottons there are several points to be observed. Weight to length is given as the cotton-spinner's standard. That is to say, so many hanks of 840 yards each must weigh 1 lb. avoirdupois. The finer the yarn, the greater the number of hanks in the pound. Every yard of the yarn must be of the same weight. This is a very strict test of accuracy in spinning, one would think, but it does not include everything. A soft, weak yarn may have the same proportion of weight to length as a fine, strong thread. A harsh and brittle cotton may now be spun, with our delicate machinery, into a very high count. Fineness, lustre, tensile strength, and regularity are, therefore, qualities which must be considered. The best general rule is to mix fibres of the same length of staple and similar structure, combining, if possible, supplementary characters. The mixture of brown Egyptian and Sea-Island is a good example. The fine softness of the latter modifies the hardness of the former, while the great tensile strength of the Egyptian adds just the quality in which Sea-Island is comparatively deficient.

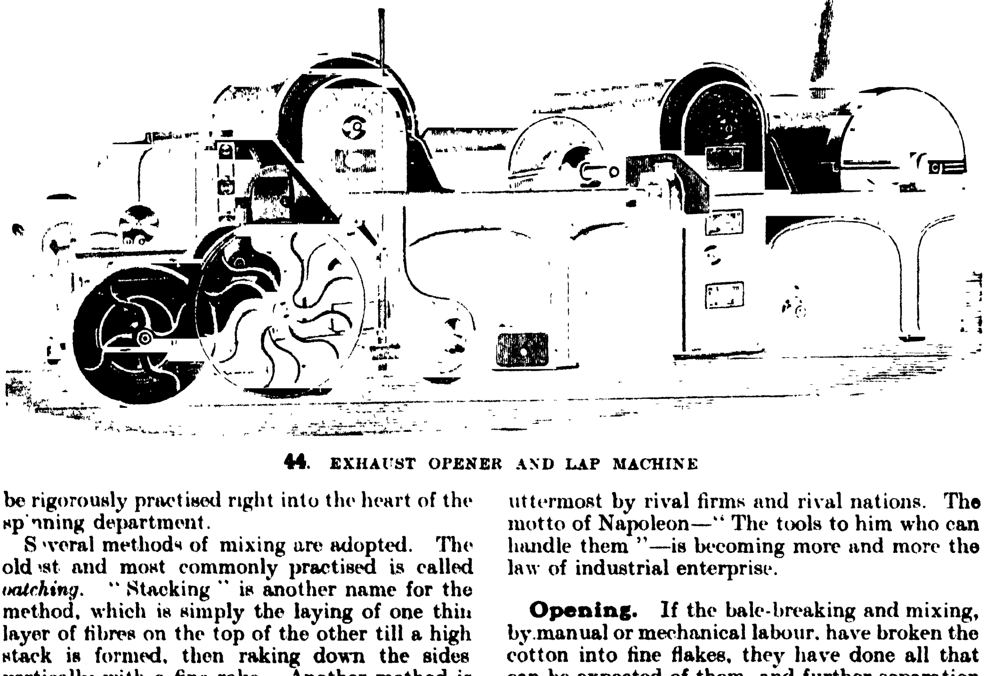
Bale Breaking. Having selected our cottons, we bring them from the stores, and proceed to break up the bales. For this purpose we have provided ourselves with a bale-breaker. Caked hard with the bale-press, the bale breaks up in lumps, and these are fed by hand on to the lattice traveller, which carries them up to the first pair of deeply fluted rollers. These move slowly, and draw the masses gently into the machine, and deliver over to another pair of rollers revolving at a higher speed. In consequence of their higher speed, the second pair of rollers drag faster than the first deliver, and thus pull asunder the clogged fibres. A third pair of rollers running behind the second pair at a rate of speed still higher, draw the staples further apart; the fourth and last pair of rollers operate in similar fashion, delivering the cotton in a fine fleecy state. While being broken, the cotton drops a marvellous collection of hard substances into the box below, varying from small pebbles



43. CONICAL WILLOW, TOP VIEW

to pieces of worn-out shoes. On this account, and to avoid injuring the fibres, the bale-breaker should be carefully used, and constantly attended.

Mixing. We have already discussed the theory of mixing, and now come to the practice. There is one difference in cotton fibres which is above and beyond all the selective power of man, and we must refer to it briefly. Cotton is a natural product, and Nature does not act on mechanical lines, but on vital principles. Examine, even with the naked eye, a staple of cotton from a single pod, and you will see that the fibres are in different stages of ripeness; some are beautifully flanged, like symmetrically curved ribbons; others are straight tubes, with the vegetable sap yet in them. Unless these fibres can be very intimately mixed, we cannot obtain from them a uniform yarn. Mixing the fibres is only the first of the devices by which the cotton-spinner endeavours to combat this obstinate fact. Combine differences to make a uniform average; that is the rule, and it must be rigorously practised right into the heart of the spinning department.



44. EXHAUST OPENER AND LAP MACHINE

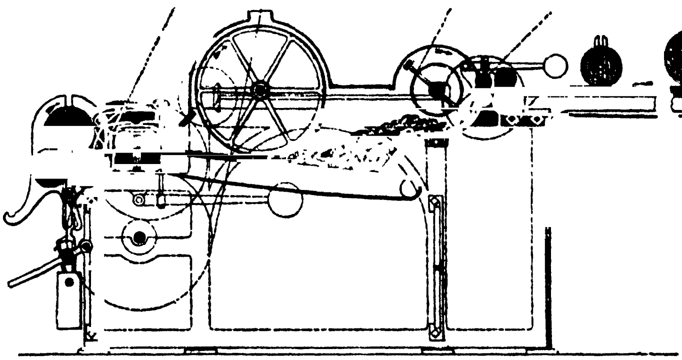
Several methods of mixing are adopted. The oldest and most commonly practised is called *matching*. "Stacking" is another name for the method, which is simply the laying of one thin layer of fibres on the top of the other till a high stack is formed, then raking down the sides vertically with a fine rake. Another method is practised in certain mills which, we think, have the future with them. The object of these mills is to dispense with human labour to the very utmost. From the bale-breaker the cotton is carried on lattice travellers that branch off in different directions, and at the end of each branch revolves a scoop, so tilted that all it receives is dropped on to the floor beneath. The speed of these scoops is varied, now quick, now slow, and the area over which the cotton is distributed varies with the centrifugal force of the revolving scoop.

When different fibres are to be combined in one yarn the mixing is sometimes deferred till the scutcher is passed. A soft fibre needs to be much more gently treated in the opening and scutching than a strong, hard fibre. The cotton-wools are therefore brought separately through to the lapping machine, which is then operated as a special machine, and there combined, to be ready for the carding. But this method cannot be detailed further, because understanding of it pre-supposes knowledge of processes not yet studied. The fact is mentioned to indicate the resources the ingenious mind discovers in processes apparently simple and almost inevitably routine.

In textile manufactures, not less than in any other human pursuit, resourcefulness carries a man forward to success. Never before in the known history of the world was there such a premium on fertility of resource in the minds of industrial workers. Every detail of every manufacturing process is being searched to the uttermost by rival firms and rival nations. The motto of Napoleon—"The tools to him who can handle them"—is becoming more and more the law of industrial enterprise.

Opening. If the bale-breaking and mixing, by manual or mechanical labour, have broken the cotton into fine flakes, they have done all that can be expected of them, and further separation of the fibres must be accomplished by other means. For this purpose a number of machines, variously named openers or willows, have been developed in a way very interesting in its early stages. The first invention was a bench, the table of which was formed by a tightly drawn netting of cords. On this table the cotton was spread, and beaten down with willow wands. Next, a man named Bowden contrived a machine by which a series of parallel rods were made to strike the cotton on the netting in rapid succession. On the other hand, however, the natives of Normandy had long used a machine composed mainly of plaited willows. "This," says Dr. Ure, "is undoubtedly the original of the English willow, both in form and denomination."

Dr. Knight says that the name given to the opener is wholly of English origin, and is simply a transfer from the willow-wand beaters on to the machine which performed the beating. We need not trouble about names; the fact remains that this old cone willow [42] contains within it the principle of all the openers since invented. Within the wattle cylinder was set a spindle carrying a series of spikes extending at right angles and graduated in length, the longest at each end and lessening in size to the middle. The cylinder was set at a slant, and on the top end was a hopper, into which the cotton was fed. Put in motion by hand or power, the spikes whirled round, beating the cotton against the sides of the cylinder, causing the dust to fly out through the open wattle, and delivering the cotton at the lower end.



45. COTTON-SCUTCHER

Later machines, of which there is a large variety, are more or less successful adaptations of the principle exhibited in that ancient contrivance. Typical models are the following:

46. MODERN SCUTCHER (Platt Bros. & Co., Oldham)

Cone Willow. A cone-shaped cylinder [43] hung horizontally within an iron casing, the outer surface of the cylinder and the inner surface of the casing studded with spikes, form the main working parts of this machine. The cylindrical cone is geared on a spindle to revolve at high speed; the casing is stationary, and its under part is an iron grid or netting. At the wide end of the cone a fan revolves above a whirling dust cage, causing a suction of air and driving out the dust. When the willow is set going and the cotton fed into the narrow end on the travelling lattice, the spikes on the cylinder and the casing pull the cotton open, while the whirling motion of the cone and the suction of the fan cause the fibre to wheel slowly down to the wide end of the cylinder, where it is received by another travelling lattice and borne outward. Teased open by the spikes and beaten hard against the grid, the cotton is made fleecy, clean, and white.

The Oldham Opener. Probably the oldest of English willows, this machine is still used for coarse cottons of a dirty class. The cylinder is roller-shaped, and so is the casing. The lower side of the case is a semi-circular cage or grid, the front half opening and closing on hinges. The cotton is fed into the opened grid, which is then closed, and the machine started. When the fibres have been sufficiently opened, the grid is lowered and the cotton thrown out. Improved models of this willow have been put on the market, advantage being taken of the rising and falling of the grid to measure by weight the quantities of cotton opened.

The Crighton Opener. The inventor of this machine had evidently paid special heed to the form of the old Norman willow. His invention, at all events, is a very close adaptation of the primitive willow. Instead of a solid, cylindrical cone studded with spikes, the

Crighton opener has a cone grid enclosing a spindle with beater arms conically graded, the cones being set apex downwards. Fed through separating rollers, the cotton passes into the wide end of the cone beaters through tubes, and goes whirling round, flying from grid to beaters, and beaters to grid, till it reaches the bottom, where it is drawn off, speeded by the fans from whose wings a constant stream of air rushes through the machine.

Exhaust Opener. The student should now be fairly well acquainted with the functions discharged by the various parts of an opener, or willow, and we therefore contentedly quote the account the makers give of this machine: "The cotton is taken from the mixing and spread on the lattice of the feeder, the feeder having collecting roller, two pairs of feed rollers, and cylinder, which deliver it to the dust trunks, over which it is drawn by the action of the exhaust fan into the cylinder of the opener. The loose dust is deposited in the dust trunks, and the cotton enters the cylinder of the opener by tin pipes, and after passing the cylinder is spread level on the first pair of cages by the action of the two exhaust fans. It then passes through the cages and two pairs of feeder rollers, is then subjected to the action of a three-wing beater, and is made into good level laps, thus obtaining the greatest amount of cleaning with the least damage to, and without stringing, the fibres of the cotton. By the use of two fans the cotton is spread level upon the cages without having to use dampers. At the commencemen of each lap the rollers at the feeder are started a short time before the lap part of the opener, and at the finish the feeder stops the same length of time before the lap part. By this means the trunks and pipes are freed from cotton when the lap part stops, and this obviates any irregularity arising from the cotton remaining in the trunks. The connection between feeder and opener is automatic in its action, and requires no attention."

Scutching. At this point, cotton-spinners who have been paying little or no attention to weight must begin. From the scutcher the cotton passes to the carder, and then there is no drawing back, except at great cost. The weight to length of a given fineness of thread has been inevitably determined. No matter how irregular the laps, the carder will inexorably reproduce every defect in the sliver, and it will go on through the whole range of spinning machines, recording the error as mercilessly as the Book of Life itself.

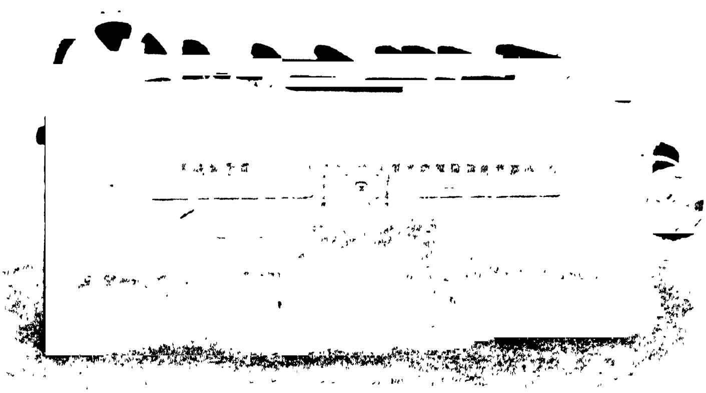
The Scutcher. There is only one scutcher though there are many different makes and numerous small improvements. In the feeding gear especially we have been greatly assisted by machine makers. Originally invented by Snodgrass, of Johnstone, N.B., and improved by Peter Cooper, of Johnstone, Crighton, of Manchester, and many other machinists, the scutcher is one of the most important machines we have. It can be adjusted to work upon any class of cotton, and produce any weight of lap required. At the fore end of the machine [46] is the lattice feed, curiously regulated by what has been called the "piano" motion. Let us explain. The area to be covered by the cotton taken in at one time is gauged on the feed-board, and it falls into gear only when the weight has been supplied. This delicacy of feed may seem adequate for many purposes, but it is not accurate enough for the cotton-spinner. A wooden roller controls the feed, and under this roller we have a series of vertical bars connected with the cone which regulates the speed of the roller. If the layer of fibre be too thick these rods instantly cause the speed of the roller to be reduced; if too thin the speed of the roller is quickened by the same automatic agency.

From the wooden roller the cotton is taken

47. COTTON AFTER SCUTCHING

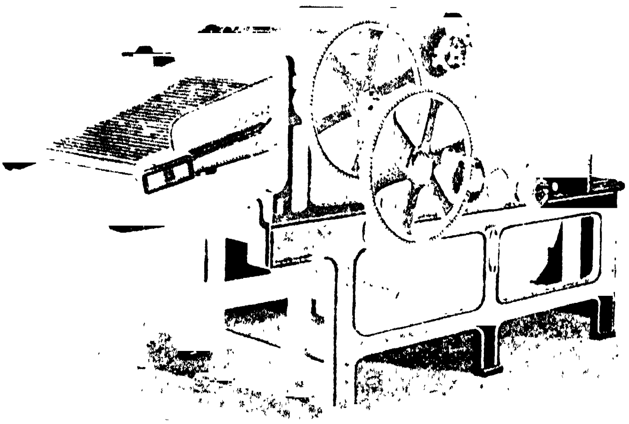
into the machine by a pair of deeply fluted rollers, and delivered over to the beater, running at the rate of 2,000 revolutions a minute, batting the fibre with its flat ends against the curved grid below, and driving out the dust. The fans are blowing hard, and waft the fleecy wool along the endless lattice to the sieve cylinder, which sucks the dust through while sending the cotton on to the second beater, revolving more rapidly than the first, upon another grid. Thence the fibre is taken hold of by another air-sucking cylinder sieve and sent forward to the lap-forming apparatus.

Though still hidden within the machine, we know that the cotton is now a fleecy mass or layer lying loosely on the conveyor. Carried forward under a guide roller, it is made to enter the first of two pairs of heavy iron rollers, which compress and firm it, while delivering to the wooden lap cylinder. Note the heavy weights on the axis of the roller [45], bearing it down upon two other rollers revolving in the same direction upon it. As the lap roller increases in thickness, the angles of the weights change, so that the pressure continues uniform. When the layers of cotton have reached the proper thickness, the whole machine, from the first pair of rollers backwards, momentarily stops, while the second pair of heavy rollers, and the rest of the lapping apparatus, run on, causing the lap to break off. The lap roller automatically descends and gives place to the one hung above, and sits waiting the call of the carder. Scutching operations have again been resumed.



49. SILK DRESSING MACHINE

Throughout our study of this process we have kept strictly to common practice. By taking the highest here and there, it is quite possible to build up an ideal cotton factory; but, so far as we have seen, the possible perfection has not been attained. Every cotton factory could be made practically automatic from the bale-breaker to the carder—at least, such automatonism as has been made from the carder onward can be attained. By wise use of the microscope and the micrometer at the bale, by careful adjustment of machine to machine, and machine to productive need, the end can be gained. By this we do not mean to displace labour; the worker will always be needed in every department of the cotton factory, but his function will be higher and better paid. It is in the direction of increased efficiency and exercise of higher intelligence that the worker must look for an amelioration of his lot, so far as it can be improved in the industrial sphere. The British workman has no superior on the face of the earth when he chooses to use his brains.



48 SILK FILLING MACHINE

SILK

Washing and Dressing Silk Waste. Raw silk comes to this country chiefly in the form of a thread, and therefore does not enter into this stage of our study. With silk waste the case is different. Silk waste is as much a raw fibre as either wool or flax, and requires treatment resembling in several respects the preparatory processes to which both these fibres are subject. Silk is among textiles what gold is among metals; it exercises a magical charm over the minds of men. After Lord Masham's famous experiment, hundreds of textile manufacturers sought to devise for themselves methods of utilising waste silks. The consequence is that we have several different processes with machines corresponding. It is impossible in this course of study to view every variation in textile manufacturing processes, and it is only fair to admit that ours is only one or two out of many processes. In some factories all silk waste is treated alike, but we think the better plan is to make a difference between cocoon and other wastes.

Treating the Cocoons. The waste from cocoons consists of broken cocoons, rough floss, unreelable knubs, and other material of similar kind. A hot solution of soap is prepared in a laundry washing machine, or dollying tub, and into the liquid the cocoon waste is put. By a simple mechanism the stampers are lifted and let fall, while the tub revolves on a tooth and ratchet arrangement. The heated liquid, with its strong detergent properties, aided by the elastic pressure of the wooden stampers, or dollies, drives out the dirt and gum. It is a simple operation, but care has to be exercised. The stampers may bruise the fibres, and the caustic of the soap may shrivel them. With a reasonable amount of care, however, we can get clean and good fibres from this tub to put into the one next it—a cold washing machine, in every way similar, excepting that a continuous stream of water runs through. The washing done, we pour the cocoons into a hydro-extractor. This is a form of drying machine, born long after the main processes of textile manufacture were determined, and therefore little used among us. Enclosed within a round iron tank, from which a waste pipe protrudes, is a wide basket composed of closely woven wire. Placing the wet silk in the wire basket, we put on the drive. Slowly for a moment, but quickly gathering enormous velocity, the basket whirls, the motion driving the moisture through the sieve into the outer tank, drying the cocoons with great rapidity.

Next, the cocoons have to be loosened so that the threads will float free. Sometimes this is done simply by beating; but a good machine has been invented for the purpose. Over a revolving tray is geared an endless band, to which a series of belts is attached. Laid on the tray, the cocoons are subjected to a rapid succession of whips from the flying belts, and effectually beaten loose. In this condition this section of the waste can be allowed to wait, for study purposes only, of course, till the other section is brought up to the same pitch of preparation.

Washing the Waste. The greater portion of the waste is a gummy mass of tangled material, scarcely recognisable as silk. When first the waste began to be utilised, it was boiled till all the gum was dissolved. Some silk manufacturers still favour the boiling process, believing that it is gentler on the fibres than any other method. Though boiling may produce good results, the process has been largely discarded in favour of retting. The masses of waste are immersed in shallow tanks containing a soapy solution. Along the bottom of each tank a coil of steam-pipes is laid. Firmly closed, the tanks are heated up to 170° F. by steam introduced into the coils, and the mixture allowed to ferment.

If injury to the fibres is to be prevented, the closest watch must be kept, and when sufficiently retted the waste should be lifted out and plunged swiftly into a dolly-tub containing a warm solution of soap. The least delay in carrying out these acts brings serious consequences, for the slimy substance bred in the fermentation hardens at once and becomes utterly insoluble.

The washing and drying of this waste differs in no important particular from that carried out on the waste cocoons.

Teasing. When silk waste first began to be utilised, it was thought that nothing less violent than the rag-tearer of the shoddy manufacturer would serve to break up those tangled masses; but of late gentler methods have been found to answer the purpose better. In some places, the wool-opener is used, and in others the "fearnought"; but the latest filling engines, allied to the thorough washing we have just seen, are the only instruments needed to disentangle the fibres.

Filling. Machine makers offer several kinds of filling engine. Some have feeding bands covered with little teeth, to hold the fibres; others have fluted drawing rollers, for the same purpose; but the engine we illustrate is among the newest models [**48**]. Laid on the travelling lattice, the fibres are borne into touch with the first of a set of rollers closely covered with little teeth that drag and pull out the tangles. Passing through combs, carried off on spiky rollers, smoothed out by roller brushes, the silk waste at last is dragged on to the large cylinder studded with rows of spikes on which it is cut to lengths of about 3 in.

Another machine much used is very direct in its action and easily worked. The feed cloth is covered with little spikes that, while feeding, drag out the silk. Two tooth-covered rollers take on the fibres, one after the other, and, being run at different speeds, pull it out. At the back of the machine is the huge cylinder, with spikes set at intervals of three or four inhes across its breadth. Driven at a moderate speed, the spikes come round and insert themselves into the tangles of silk, and pull out a range of threads. Every row of spikes takes a share, and the cylinder thus becomes clad with silk fibres. The attendant of the machine cuts out the spoil carried by the spikes, and forms them into what are called *stricks*, the breadth of the cylinder, and each fibre the length of the interval between the spikes.

Whatever may be the form of the filling engine, its main object is to card out the fibres and cut them down to a length suitable for passing through the spinning machines constructed for fibres of moderate length. If the machine accomplishes that purpose, we should venture to think that its principle of working can hardly be strange to us.

Dressing. The dressing machine is a remarkable contrivance, original in conception and highly efficient [49]. First we take the *stricks* derived from the filling engine, and fix them into wooden clamps, technically called "books." These are fixed into the bed of the dressing machine. Observe on the machine a broad, endless band, stretched between two heavy rollers, and upon the band at short intervals, belts of heckle teeth, named combs. When the stricks are properly set and the machine running, the band brings those combs through the fibres, and they take away as many short or doubled fibres as will come, while finely dividing and combing out the fibres that remain. After a time the combs come away clean, showing that the silk has been sufficiently treated. Now stop the machine and lift out the clamps. The fibres there are said to be the first draught, and are of the highest quality. From the combs the fibres are cleaned and put into the wooden clamps on the bed of the machine. The travelling combs gently, but firmly, pull out the shorter silk threads, leaving in the clamps those which are of sufficient length and regularity to take the combing without yielding. These fibres are named second draughts, and rank second in quality. The process is repeated another three or four times, and nothing is left save the very short fibres, which, under the term noils, pass through the common carders in a manner we shall study shortly.

Improved Machines. Makers of machines for every department of the textile industry are constantly devising new things. Silk dressing is no exception, and it is quite impossible for practical men to keep pace with the inventors. One of the machines which has come lately into use is worth noting, because of its special character. In this contrivance, the main features of which are three cylinders, the stricks are wound on to wooden rods, which are clamped on to the centre cylinder. A huge affair this central cylinder moves slowly and majestically round, while the two side cylinders, clothed with serried teeth, run in opposite directions at a good speed. The motion of the two outside cylinders is always opposite to that of the centre cylinder, and the teeth, therefore, pull at the fibres fixed on its surface. After one end has been combed, you simply remove the rods, reverse the fibres, and fix them in again while the machine is running. The machine is certainly simple and very easy to work.

Automatic Dressing. In the great silk works at Manningham, the aim of automatic perfection is steadily pursued. Here, instead of being cut into stricks at the filling engine, the fibres are formed into a lap on the opener or willow. These laps are laid on a feeding table, with a rocking filling head. Parallel with the table is a moving comb. With the forward movement of the rocking filler the fibres are thrown on to the comb and pulled. As the rocker falls back, a knife comes down and severs the taut fibres. The comb moves forward, to traverse three machines in a similar way, and then from above and below come sets of nips which take away the fibres and, on endless bands, convey them to the carding cylinders. Borne on to the end of the series, the fibres are finely dressed and ready for being formed into slivers.

Wild Silks. Up to the time when the process we have examined had come into general knowledge many of the "tusseh," or wild silks, of China, India, Japan, and America, though sometimes reeled and worn by the natives of the East, were almost wholly disregarded by the silk workers of Europe. The yamamai of Japan, the ailanthus of Chefoo, and several of the Indian wild silks, though true tussehs, were reeled and thrown by Europeans, but the greater number of the varieties of that class could not be utilised among us, because of the cost the reeling involved. The waste-silk process has completely obviated the difficulty presented by the tangled and gummy cocoons. By treating the wild silks in the same way as the broken cocoons and knubs of the cultivated varieties, we obtain silk yarns of a very high quality. Indeed, it is sometimes asserted that some of the tussehs so treated are equal in lustre and other qualities to the very finest of the cultivated kinds. We hardly venture so far. For one thing, the wild silks give more anxiety and trouble to the dyers and bleachers, many of them being of an indelible brown shade. It is true that methods of bleaching them have been devised ; but these methods involve both trouble and expense. Even so, the waste-silk process has in this manner vastly enlarged the sources of silk supply. If the silk industry of Great Britain were to renew its former prosperity, the vast numbers of wild silkworms in Indian forests would be properly utilised. Tusseh cocoons, as we have hinted, are treated like the broken cocoons of the cultivated varieties. We hardly need, therefore, go over the process again.

In some degree our study of silk waste has carried us beyond the precise limits of purely preparatory processes, and led to trenching somewhat on the carding and combing processes, which should be studied thoroughly by themselves. The carding proper of silk waste has yet to come, however, and then that class of fibre will fall into line with the others.

Itineraries of Travel in Austria and Hungary. A Guide to the Art Treasures, Historic Sites, and Scenic Beauties of these Countries

By J. A. HAMMERTON and WILLIAM DURBAN, B.A.

AUSTRIA

Austria is an ideal country for the intelligent traveller. This great section of South Central Europe is more composite in its nationalities than any other portion of the Continent, and all its diverse populations are extremely interesting. Here ancient and modern history blend in almost bewildering combination, so that the tourist's attention is constantly invited to the consideration of strange contrasts. Austria has only recently begun to receive the acknowledgment it merits as a resort for travel, study, health, and recreation. The mighty Danube and its tributaries, the majestic mountain ranges, and the exquisite lakes, all lie within easy compass, so that nowhere is a delightful tour more conveniently to be arranged within the scope of a brief holiday season. The wonderful mountain scenery includes the Ortler Group, the Carinthian and Styrian Alps, and many of the grandest of the Dolomite peaks. Much of the famous and incomparable Tyrolese region is within the Austrian Empire, and many of the lakes are of the utmost loveliness. Travel in Austria is now greatly facilitated and economised by the zone system, as well as by the arrangements made under the bureau of the State railways, which gives courteous and specific information as to conditions and fares. *A week in Austria* is often snatched by those whose main object is to visit Germany, or Italy, or Switzerland. Such an interlude affords a delightful opportunity of making acquaintance with Vienna, and with a few of the beautiful Danubian cities, such as Passau, Linz, and Presburg. But more than this is not possible.

A Fortnight in Austria. Two weeks enable one to see a good deal of the country, and can scarcely be excelled as a holiday. The spots to be visited are full of the most varied fascination.

FIRST DAY. The traveller most conveniently commences with PASSAU, which he reaches by rail from Munich, or else from Nuremberg through Ratisbon. At the charming old city of Passau we strike the Danube and cross the Austrian boundary. This is one of the most beautiful spots on the whole course of the great river. The striking confluence of the Danube, Inn, and Ilz. Lovely views from the heights near the banks of these rivers. *Cathedral of St. Stephen*, one of the finest of all ancient Teutonic churches, founded in the fifth century. The *Parade Platz* in front of the Cathedral, with great bronze statue of Maximilian I. The noble *Rathhaus*, or town hall, with council chamber embellished with historic pictures. The quaint, ancient churches of the *Heilige Kreuz* and *Maria Parz*, the latter containing the tomb of Abbess Gisela, Queen of Hungary.

SECOND DAY. This would be spent in the beautiful environs of Passau. The pilgrimage church of *Maria Hilf*. The fortress of *Oberhaus*, in a romantic spot by the Ilz. The *Ilz Bridge* and the *Belvedere*. The *Klosterberg*, with wonderful views.

THIRD DAY. Steamboat journey to LINZ. Scenery grander than that of the Rhine, the noble stream winding its way through precipitous wooded hills, with rich vineyards on the lower slopes. Linz is reached in the evening.

FOURTH DAY. Linz is a beautiful and characteristic Austrian city, and the capital of Upper Austria. Splendid *bridge* over the Danube. The fine *Haupt Platz*, in which rises the lofty Trinity Column. The noble thoroughfares of the *Klostergasse*, the *Schmiedt or Gasse*, the *Dom Gasse* and the *Land Strasse*. The ancient *Cathedral*. The new and beautiful Gothic *Cathedral*, with votive chapel richly decorated with marble mosaics, gilding, and stained glass. Short trip to the *Postlingberg* and the pilgrimage church of *St. Magdalena*, from both of which are obtained magnificent views of the Danube and the country.

FIFTH DAY. Another glorious day's ride through some of the most fascinating scenery in Europe is obtained by going from Linz to VIENNA, on the Danube. Everywhere are dotted romantic old castles perched on picturesque crags. Near the island of *Worth* is the *Greiner Schwall* (surging water), and further on is the famous "Strudel" or whirlpool. The day's voyage is a memorable one.

SIXTH DAY. The city of VIENNA is on the Wien, a short distance from the Danube. Many days might be spent here, for so much is to be seen. The Church of St. Stephen, the *Cathedral* of Vienna, the Giant's Door and the two towers called the Heidenthürme. The famous chapel of St. Barbara; the Thekla Choir, with the beautiful sarcophagus of Kaiser Frederick III.; the famous pulpit in the nave; the great catacombs under the church; the tower of St. Stephen with grand view of the battlefields of Lobau, Wagram, and Essling.

SEVENTH DAY. On the second day in VIENNA, visit the *Graben*, the chief business street, formerly the great moat, now containing magnificent shops, and in its central portion the lofty *Trinity Column*. The *Hofburg*, or Royal Palace, with monument of Francis II, and the splendid statues of Joseph II, Archduke Charles, Prince Eugene, and Francis I. In the Hofburg are the vast *Imperial Library* and the famous Treasury, full of precious jewels, regalia, and priceless historic relics and curiosities, including the crown of Charlemagne, and the celebrated Florentine diamond. The *Imperial Picture Gallery*, with masterpieces of nearly all schools. Grand specimens of Titian, Raphael, Correggio, Parmigianino, Giorgione, Dürer, Rubens, etc.

EIGHTH DAY. A third day would be devoted to the sights of the city. *Academy of Art*, with wonderful picture galleries, containing famous pictures by nearly all the great artists of various countries, the most famous being the "Cupid" of Titian, the "Two Boys Playing at Dice" of Murillo, the "Boreas" of Rubens, and several landscapes of Ruysdael. The *Ring Strasse* and the *Franz Josephs Quai*, which together encircle the inner city and form one of the most imposing streets in all Europe. The magnificent buildings to be inspected are the *Exchange*, the *Handels Museum of Manufactures*, the beautiful Gothic church called the *Votivkirche*, the splendid *University*, the sumptuous *Rathhaus*, the *Historical Museum*, the *Hofburg Theatre*, richly adorned with paintings, the *Houses of Parliament*, the *Palace of Justice*, the grand *Maria Theresa Monument*, the *Natural History Museum*, the *Art-History Museum* the *Imperial Opera House*, and the *Museum of Industry*.

Ninth Day. The outer districts of Vienna contain a world of interest in themselves. A delightful half-day may be spent in the celebrated park and forest called the *Prater*, in which the Haupt-Allee, or principal avenue, with its quadruple row of grand old chestnut-trees, is Vienna's most fashionable suburban resort. In the north-western part of Vienna are many interesting old streets, adorned with picturesque statues, fountains and churches, and with the quaint old *Palace and Picture Galleries of Count Harrach*, to which is attached the beautiful *Winter Garden*.

Tenth Day. Journey to Botzen. This is a long, but most interesting day's ride through one of the most picturesque regions of the Austrian Empire. It brings the tourist into the very heart of the beautiful Austrian Tyrol, and lands him in the delightful old city of Botzen, situated in the midst of the glorious Tyrolese Alps.

Eleventh Day. At Botzen the tourist is at the gateway to some of the most superb scenery of Central Europe. See the Gothic *Parish Church* with beautiful open tower: the *Franciscan Monastery*; the *Calvarienberg*, a delightful little excursion commanding splendid mountain views.

Twelfth Day. Glorious ride over the *Brenner Pass*, by the highest mountain railway in Europe, and through scenery that is indescribably beautiful, to Innsbruck.

Thirteenth Day. At Innsbruck the tourist is in the capital of Tyrol, and he is at once fascinated with the attraction both of the city itself and of its glorious situation, 2,000 ft. above the sea-level, in the midst of a circle of majestic mountains. The great sight of the city is the *Hofkirche*, containing the world-famed and sumptuous monument to Maximilian I, which occupies all the centre of the nave. The church also contains a marble monument of Andrew Hofer. The neighbourhood of Innsbruck affords a great choice of charming little excursions.

Fourteenth Day. The traveller will leave Austria by taking train to Munich.

Longer Tours. If *three weeks* can be devoted to a tour in Austria, the third week should include visits to Salzburg and a few of the beautiful lakes, such as the Achensee, the Kammersee, the Traumsee, and the Wallersee. A *month* would enable the visitor to include an extension into Bohemia, taking in not only the quaint, historic capital Prague, but also such beauty spots as Pilsen, Marienbad, Siebenberge, Eger, Karlsbad, etc.

Travel and Food. Travel in Austria is rendered somewhat expensive from the fact that the leading coin, the kroner—equivalent to about two shillings—does not go much farther than does the shilling in England. Also the railway fares from Austria are somewhat higher than in Germany. Meals in Austria are somewhat luxurious. Fruit is very abundant and delicious, and fine caviare (the roe of the sturgeon caught in the Danube) is a common commodity. Nowhere can better coffee be obtained than the decoction prepared throughout this country. It is served with whipped cream, and is styled "Kaffee mit Obers."

Fares. The fare from London to Vienna is: First class, single, £7 9s. 8d.; return, £11 12s. Second class, £5 4s. 5d.; return, £8 1s. 6d.

Books. Much interesting literature of Austrian travel is current. Amongst the best books in the category may be mentioned Mrs. Donner's "Down the Danube," Browning's "Girl's Wanderings in Austria," Reeve's "Residence in Vienna," Hodgson's "Wanderings through Unknown Austria," Tissot's "Unknown Austria," McCracken's "Tyrol," etc.

HUNGARY

The famous land of the Magyars is, in natural resources, one of the richest sections of the Continent, and it is, in manifold respects, one of the most interesting. Hungary constitutes in area the larger portion of the great dual Empire-Kingdom. It is a country of ancient historic romance. The regions of the Huns must ever attract lovers of history and literature. The wild beauty of the Carpathians is, year by year, admired by an increasing number of tourists. Hungary owns the most picturesque reaches of the noble Danube. The vast and fertile wheat-growing areas of the "black earth" plains form a unique feature. The fascinating character of the peculiar races—Magyars, Slovaks, Croats, Dalmatians, Ruthenians, and Zingari (gipsies)—is acknowledged by all visitors. English people are always specially welcome in Hungary. The popular sense of gratitude to our nation for sympathy manifested in the days of Kossuth is as lively as ever. Very memorable is a visit to any Hungarian town or village on any national feast day. The beautiful tsardas, or national dance, is performed with singular grace.

Travel and Food. Travelling in Hungary used to be inconvenient and expensive, but the adoption of the zone tariff has entirely changed the conditions. The land is one of great fertility. Fruit and all kinds of provisions are abundant and cheap. The inns are almost everywhere exceedingly comfortable, the domestic life of the people being of a high standard. Hungary is a great wine-producing country. The traffic on the Danube and on the rivers Theiss, Drave, and Maros is immense, and the accommodation on the fine steamers for both night and day voyages is excellent. No country supplies pleasanter conditions for the tourist. Many of the customs of this interesting country are altogether unique. The visitor finds himself amongst a most hospitable and genial people. He is presented with many dishes he never saw elsewhere. The famous "paprika," a generic term for game or fowl prepared with a mild species of red pepper, is one of the national viands constantly in evidence. The people revel in delicious fruit, and the land overflows with plenty. In almost every large restaurant bands of "zingari," or gipsy wandering musicians, perform. These play the most weird music with remarkable skill, and the itinerant orchestras are exceedingly popular.

A Week in Hungary. This is frequently spent by tourists as an extension of an Austrian tour. It is naturally occupied in voyaging down the Danube, a stay of a few days at Buda-Pest, and a further passage down the great river as far as Orsova.

A Fortnight in Hungary. This is a delightful experience, as it affords time for viewing some of the most picturesque features of this remarkable country.

First Day. The steamer leaves Vienna at 7 a.m. for the twelve hours' sail down the glorious Danube to Buda-Pest, which is reached at 7 p.m. This is one of the most charming river trips in the world. Indeed, it is hardly excelled by an experience of the kind anywhere. Historic spots abound on the banks.

Second Day. Pest is one of the most charmingly situated cities of Europe. It is on the north bank of the Danube, Buda being on the south. Pest is one of the great historic cities of the continent, as it was founded by the Romans and was the scene of tremendous struggles with the Turks. It is to-day the seat of the wonderfully prosperous grain-trade of Central Europe. Splendid modern buildings adorn the grand quays of the Danube and many of the modern streets. The fine *Academy*, including the National Picture Gallery. Among the many masterpieces of various schools are six splendid pictures by Murillo. The beautiful promenade along the Danube, known as the *Franz Josephs Quai*, the old Gothic *Stadt Pfarr Kirche*, the famous colossal *corn elevator*, the fine *Custom House*, should be seen the first day. Early in the morning, every day in the week, the interesting open-air fruit and vegetable market is in full swing on one portion of the quay. The peasants and farmers attend in great numbers, in their quaint national costumes.

Third Day. On the second day in Pest visit the *National Museum*, full of superb local antiquities. The picture gallery contains 600 paintings, mostly by modern Hungarian artists, including Munkacsy. The *Parliament House*, the *Cemetery*, containing monuments of Batthyany, Deák, and other patriots, and the splendid *bridges* over the Danube—magnificent works of engineering—will make a full day's sightseeing.

Fourth Day. Excursion in morning to the lovely *Margarethen Insel*. This little island in the midst of the Danube is a great "cure" resort as well as a popular garden. It contains famous thermal establishments, and also wonderful natural hot sulphur baths, and at the luxurious *Bad Haus* are also electric and other medical baths. The afternoon may be devoted to a delightful excursion by carriage to the park in the environs of Pest known as the *Stadtwäldchen*. Here are noted concert halls and restaurants on the pretty islands in the lake.

Fifth Day. The tourist would now direct his attention to Buda, the twin capital on the opposite bank of the Danube, called Ofen by the Magyars; a magnificent old town. Visit Maria Theresa's beautiful palace; lovely view from the gardens. In this palace are kept the splendid objects belonging to the Hungarian regalia, including the famous crown of St. Stephen. The interesting *Palace Bazaar* on the quay, with fine view of the Danube. The celebrated *Matthias Kirche*, the Cathedral of Buda, which was used as a mosque by the Turks. The present Kaiser-King Franz Joseph and his consort, Elizabeth, were here crowned in 1867. The famous sulphur baths of the Danube at Buda are much frequented. The *Kaiserbad*, with its eleven very hot springs, is the most popular.

Sixth Day. A second day is necessary to see Buda. The magnificent *Blocksberg*, an immense crag by the Danube, crowned by the imposing citadel, with enchanting views from the top. The famous and curious *Turkish Mosque*, with beautiful garden: a very popular pleasure resort. The fine suburb of *Schwabenberg*, where are many handsome villas. The prospect is exceedingly beautiful. Cog-railway reaches the summit in twenty minutes.

Seventh Day. By train from Pest to Stuhl Weissenburg. Here the ancient kings of Hungary were crowned. One of the most interesting cities in the country. It is embosomed in beautiful vineyards, amongst which delightful drives may be indulged in. The old *Episcopal Palace* and the *Cathedral* are the most conspicuous buildings. The town has large calico-printing works, and does a great trade in fruit and wine. Here native life may be seen in its typical characteristics.

Eighth Day. Excursion to Lake Balaton, called by the Germans the Plattensee, Hungary's largest lake. It abounds in fine fish, and is surrounded by volcanic hills and beautiful vineyards. Steamer twice a day to Füred, where are famous carbonic acid baths. A crowded summer resort. Back to Pest.

Ninth Day. Start down the Danube for Orsova. A grand voyage of 36 hours through captivating scenery. The view for some hours below Buda-Pest is somewhat monotonous, as the river traverses the vast Hungarian wheat-growing plains. But all is changed after passing the influx of the Drave. The tourist sleeps a night on board the splendid steamer.

Tenth Day. Down the Danube. On the right bank are picturesque vine-clad hills, with many ruined castles. During the day, towards evening, Belgrade is reached, and those who wish to visit Servia disembark at this point, the capital of that country. The steamer reaches the famous Defile of Kasan, the grandest scene on the mighty river. Before reaching Orsova the celebrated inscription of Trajan is seen on the perpendicular cliffs.

Eleventh Day. Orsova is the last town in Hungary, touching the Roumanian frontier. It is the gateway to the valley of the Czerna, one of the loveliest districts in all Europe, in the foothills of the Lower Carpathians.

Twelfth Day. From Orsova, visit the *Baths of Hercules*. This Carpathian paradise is alone worth all the trouble and expense of the journey. It was the favourite summer resting-place of the unfortunate Empress, Queen Elizabeth. In the old Roman days it was a celebrated health resort. The sulphur baths are amongst the most powerful chalybeate springs known. The excursion from Orsova is through enchanting scenery on the Roumanian border.

Thirteenth Day. Railway to Buda-Pest. The long journey is through a varied and interesting country.

Fourteenth Day. From Buda-Pest to Vienna by rail.

Longer Tours. Those who wish to spend *three weeks* in the country can, by way of extension, enjoy an expedition into the Tatra, the lofty range of the West Carpathians. *A month* in Hungary affords an opportunity of excursions in the fine district between Agram and Fiume.

The fare from London to Buda-Pest is: First class, single, £9 14s. 8d.; return, £16 3s. 10d. Second class, single, £6 12s. 5d.; return, £11 1s. 4d.

Books. The literature of Hungarian travel is usually combined with descriptions of the whole Austro-Hungarian Empire. Specially interesting are Dowie's "Girl in the Carpathians," Gerard's "Land Beyond the Forest," Pennell's "To Gipsy-Land," an anonymous work in two volumes, entitled "Magyarland," and Cross's "Round about the Carpathians."

By WILLIAM R. COPE

Principles Concerning Areas of Plane Figures. In order to understand more thoroughly the following principles, it would be well for beginners to go through Euclid's demonstrations of them. It should also be remembered that the boundary line, or *perimeter*, of any closed figure encloses an amount of surface called its *area*.

1. *Parallelograms* upon the same base, or upon equal bases, and between the same parallels, are equal [Euc. I. 35 and 36]. Thus $ABCD = ABDE$ [**320**], or $ABCD = ABFE$ [**321**], or $ABCD = EFHG$ [**322**].

2. *Triangles* upon the same base, or upon equal bases, and between the same parallels, are equal [Euc. I. 37 and 38]. Thus, $ABC = DBC$ [**323**], or $ABC = DEF$ [**324**].

3. If a parallelogram and a triangle be upon the same base, and between the same parallels, the parallelogram shall be double of the triangle [Euc. I. 41]. Thus, $ABCD =$ twice ABC [**325**], or $ABCD =$ twice EBC [**326**].

4. The square on the hypotenuse of a right-angled triangle is equal to the sum of the squares on the other two sides [Euc. I. 47]. This fact was discovered by Pythagoras, 580 B.C.

Thus, the square $ABCD =$ square $EGFB +$ square $AEHJ$ [**327**].

NOTE. This is true of other figures constructed upon the sides of a right-angled triangle, as long as they are similar. Thus, the hexagon $ABKLMN =$ hexagon $BEOPQR +$ hexagon $AESTUV$ [**327**].

5. *Parallelograms* and *triangles* upon the same base have their areas in the same ratio as their altitude. Thus, $ABEF =$ twice $ABCD$ [**328**], or $ABD =$ four times ABC [**329**].

6. Parallelograms and triangles *of the same altitude* are to one another as their bases [Euc. VI. 1]. Thus, $ABCD = \frac{2}{3} BEFG$ [**330**], or $ABC =$ three times ABE [**331**].

7. The area of a rectangle is equal to that of a triangle upon the same base, but having twice the altitude. Thus, $ABCD = ABE$ [**332**].

8. The areas of circles are proportional to the squares on their diameters. Thus, the circle $ABC =$ four times DEF [**333**].

Construction of Areas Equal to or Proportional to Others.

334. TO DRAW AN ISOSCELES TRIANGLE WHOSE AREA SHALL BE HALF THAT OF THE GIVEN RECTANGLE $ABCD$. Bisect AB by the perpendicular FE, cutting CD in E. Join AE and BE, and AEB is the required triangle.

335. TO CONSTRUCT A RECTANGLE EQUAL IN AREA TO THE GIVEN TRIANGLE ABC. At A and B erect AE and BF perpendiculars to AB. From C draw CD perpendicular to AB (or AB produced), and cutting it in D. Bisect CD in G, and draw EGF parallel to AB and cutting AE in E and BF in F. Then $ABFE$ is the rectangle required.

NOTE. The rectangle $AHJK$ shows that the area of a triangle may also be expressed as the altitude multiplied by half the base.

336. TO CONSTRUCT A RECTANGLE EQUAL IN AREA TO THE GIVEN RECTANGLE $ABCD$, AND ONE SIDE TO BE EQUAL TO GH. Then the other side of the required rectangle must be a fourth proportional to AB, GH, and AD. Set off along AB from A, the given side AE equal to GH. Join E and D, and through B draw BF parallel to ED, cutting AD produced in F. Through F draw FG parallel to AB, and through E draw EG parallel to AF. Then $AEGF$ is the required rectangle.

337. TO CONSTRUCT A TRIANGLE OF A GIVEN HEIGHT DE, AND EQUAL IN AREA TO THE GIVEN TRIANGLE ABC. Through A draw FG perpendicular to BC and equal to the given height DE. Join FB and FC, and through A draw AJ and AH parallel to FB and FC respectively, cutting BC in J and H. Join FJ and FH, then FJH is the triangle required.

338. TO CONSTRUCT AN ISOSCELES TRIANGLE EQUAL IN AREA TO THE GIVEN TRIANGLE ABC, AND WITH ONE OF ITS ANGLES EQUAL TO ONE OF THOSE IN THE TRIANGLE ABC. Find the mean proportional BF to BA and BC. With centre B and radius BF describe an arc cutting BA produced in G and BC in H. Join G and H, then GBH is the required triangle.

339. ON A BASE EQUAL TO DE TO DESCRIBE A TRIANGLE EQUAL IN AREA TO THE GIVEN TRIANGLE ABC. On BC, or BC produced, set off BF equal to DE. Draw AF, and from C draw CG parallel to AF. Join G and F. Then GBF is the triangle required.

340. TO TONSTRUCT AN EQUILATERAL TRIANGLE EQUAL IN AREA TO ANY GIVEN TRIANGLE ABK. Through K draw KC parallel to the base AB. Bisect AB by the perpendicular EC cutting KC in C. Join CA and CB, thus obtaining an isosceles triangle, CAB, equal in area to ABK. Upon AB describe the equilateral triangle ABD. Now find the mean proportional EF to the altitudes ED and EC of the two triangles ABD and ABC. With E as centre, and radius EF, describe an arc cutting EC in G. Through G draw GH and GJ parallel to DA and DB respectively, and cutting AB produced in H and J. Then GHJ is the required triangle.

341. TO CONSTRUCT A RECTANGLE WITH SIDES IN THE RATIO OF 3 TO 4, AND AN AREA EQUAL TO THE SQUARE ON AB. Draw any straight line CD, divided in the ratio 3 to 4 at E. Find a mean proportional EF to CE and ED. Produce EF to G, making EG equal to AB. Draw GJ and GH

parallel to *FC* and *FD* respectively, cutting *CD* produced in *J* and *H*. Construct the required rectangle with sides equal to *EJ* and *EH*, as shown.

342. To Construct a Square Equal in Area to a Given Triangle *ABC*. On the base *BC* make a rectangle *BCDE* equal to the triangle *ABC*. Find a mean proportional *CG* to *BC* and *CD*. Then *CG* is one side of the required square.

343. To Construct a Rectangle Equal in Area to a Given Circle *ABC* (approximate). Draw any radius *DB* for a short side of the rectangle. Divide *DB* into 7 equal parts. Draw *BE* perpendicular to *DB*, and equal to 3¼ times *DB*. Complete the rectangle *DBEF* as shown.

344. To Construct a Parallelogram Equal in Area to a Given Trapezoid *ABCD*. Join two opposite corners, *D* and *B*, and through *C* draw *CE* parallel to *DB*, cutting *AB* produced in *E*. Bisect *AE* in *F*. From *F* draw *FG* parallel to *AD*, cutting *DC* produced in *G*. Then *AFGD* is the required parallelogram.

345. To Construct a Parallelogram Equal in Area and Perimeter to the Given Triangle *ABC*. Produce either side, say *BC*, to *D*, making *CD* equal to *CA*. Bisect *AB* in *E*, and *BD* in *F*. Through *C* draw *CH* parallel to *BA*. With *B* as centre, and radius *BF*, describe an arc cutting *CH* in *G*. Join *BG*, and through *E* draw *EH* parallel to *BG*. Then *EBGH* is the required parallelogram.

346. To Draw a Triangle of a Given Shape *ABC* and Area Equal to, say, 3 sq. in. From *A* draw a perpendicular *AD* to *BC*, and bisect it in *E*. Make the rectangle *BCFG* equal in area to the triangle *ABC*. With *B* as centre, and radius *BG*, describe the arc *GH*, cutting *CB* produced in *H*. Find *BJ* the mean proportional to *CB* and *BH*. Along *BJ*, or *BJ* produced, set off *BK* equal to $\sqrt{3}$ (the mean proportion of 3 and 1). Join *JA*, and from *K* draw *KL* parallel to *JA*, and cutting *AB* in *L*. Through *L* draw *LM* parallel to *AC*. Then *LBM* is the required triangle.

347. To Construct an Isosceles Triangle Equal in Area to a Given Trapezium *ABCD*, with One Side *AB* Common to Both Figures. Join *AC*, and from *D* draw *DE* parallel to *AC*, and cutting *BC* produced in *E*. Join *AE*. Then the triangle *ABE* is equal to the trapezium. Bisect *AB* by the perpendicular *FG*, and through *E* draw *EG* parallel to *AB*, and cutting *FG* in *G*. Draw *GA* and *GB*. Then *ABG* is the required triangle.

348. To Construct any Figure Similar to a Given One *ABCDE*, and Having its Area in any Proportion to it, say, 3 : 1. Let *AB* be the one equal part, and make *AF* equal to 3 times *AB*. Find a mean proportional *AG* to *AB* and *AF*. Then *AG* is the base of the required figure to be completed as shown.

349. To Describe a Circle Equal in Area to the Difference of Two Others. Let *AB* be the diameter of one given circle, and upon *AB* describe the circle. With *A* as centre, and *AC* (the diameter of the other given circle) as radius, cut the first circle in *C*. Join *AC* and upon it describe the second given circle. Join *CB* and upon *CB* describe the required circle.

350. To Construct a Figure Similar to a Given One *ABC*, but Half its Area. On *BC* describe a semicircle, and bisect it by *DE*. Draw *BE* and make *BF* equal to it. Through *F* draw *FG* parallel to *CA*. *GBF* is the required figure.

351. To Describe a Circle Equal in Area to the Sum of Two Others. Draw *AC* and *CB* (the diameters of the given circles) perpendicular to each other, and describe the given circles upon *AC* and *CB*. Join *AB*, which is the diameter of the required circle.

352. To Make a Square whose Area shall be Equal to 5 sq. in. Draw a line *AC*, 1 in. long, and perpendicular to it *CB*, 2 in. long. Join *AB*, which is equal to $\sqrt{5}$. Upon *AB* describe the required square *ABDE*.

353. To Make a Square Equal in Area to a Given Rectangle *ABCD*. Find a mean proportional *CF* to *BC* and *CD*. Upon *CF* describe the required square *CFGH*.

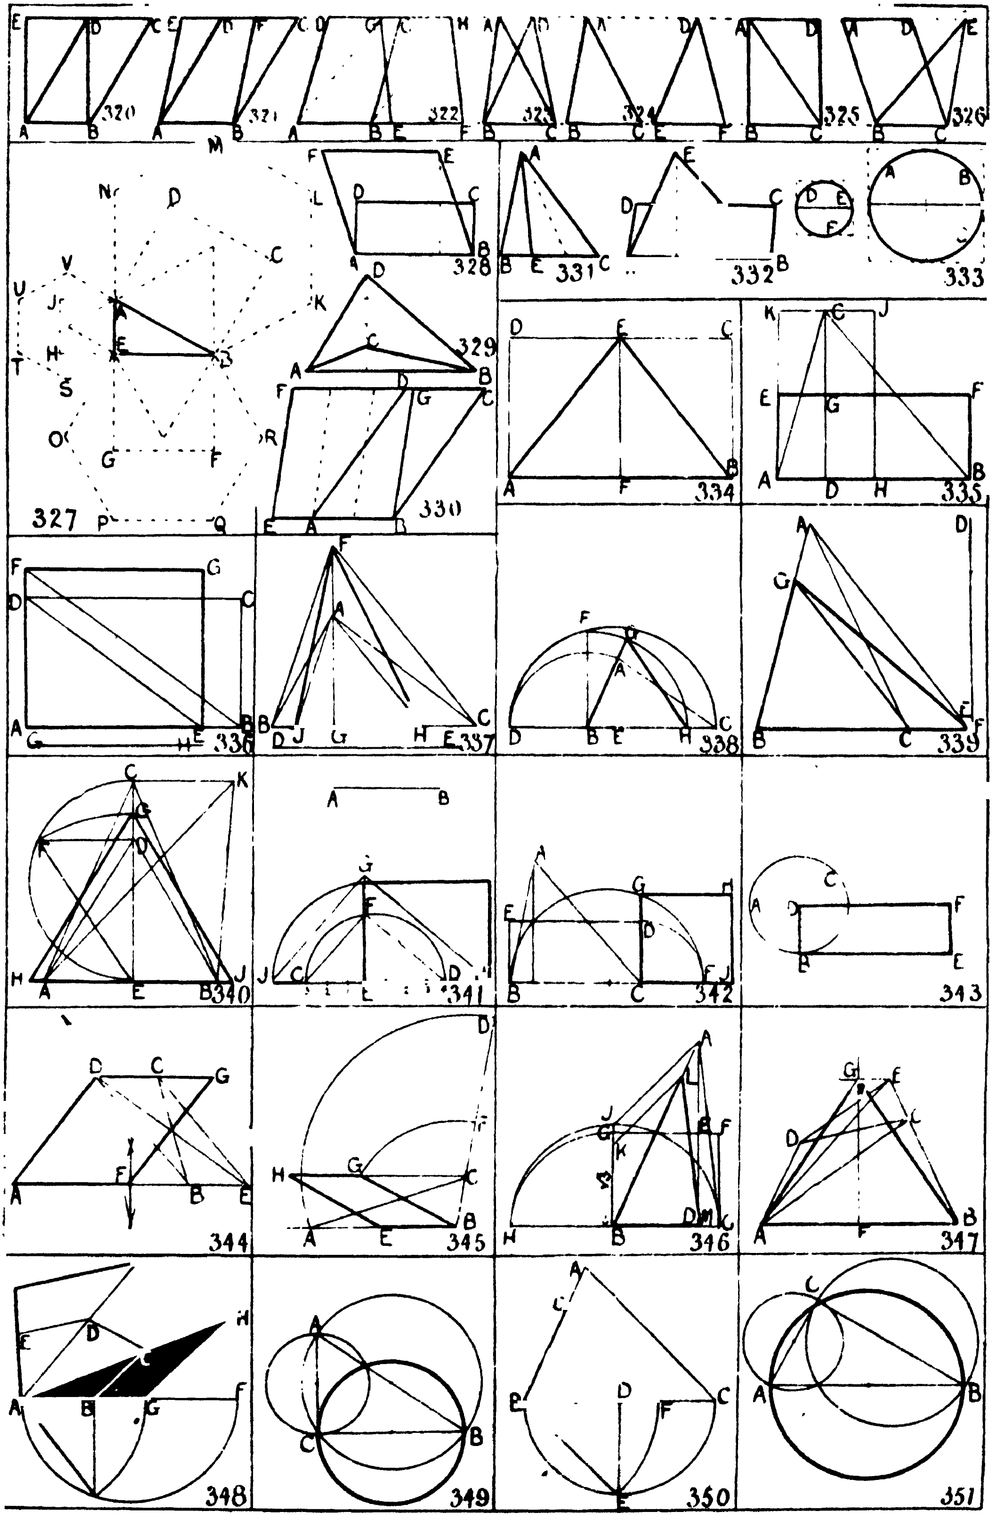
354. To Construct a Square whose Area shall be a Fractional Part (say ⅔) of that of a Given Square *ABCD*. Upon any straight line *EF* set off *EG* and *GF*, two and three convenient equal divisions. Upon *EF* describe a semicircle, and find *GH* the mean proportional to *EG* and *GF*. Join *HE* and *HF*. From *F* along *FH*, set off *FJ* equal to the length of the side of the given square. Through *J* draw *JK* parallel to *HE*. Upon *JK* describe the required square, as shown.

355. To Construct a Rectangle Equal in Area to a Given Square *ABCD*, and One Side of the Rectangle to be a Certain Length, as *EA*. Place the given side, *EA*, of the rectangle perpendicular to a side of the square, as *EA* and *AD*. Join *DE* and bisect it by the perpendicular through *F*, cutting *EA* in *G*. With *G* as centre, and *GE* or *GD* as radius, describe a semicircle, cutting *EA* produced in *H*. Then *AH* is the other side of the required rectangle, as shown.

356. To Reduce any Irregular Figure, as *ABCDE*, to a Triangle of Equal Area. Join *AC*, and through *B* draw *BF* parallel to *AC* and meeting *DC* produced in *F*. Join *AF*, and the triangle *AFC* equals the triangle *ABC* in area. Join *AD*, and through *E* draw *EG* parallel to *AD*, cutting *CD* in *G*. Join *AG*, and the triangle *AEG* equals (in area) the triangle *EGD*. Then *AFG* is the required triangle.

357. To Construct a Triangle Equal in Area to a Regular Polygon, as *ABCDEF*. Divide the polygon into equal triangles by lines drawn through the centre *G*, then *GCD* is ⅙ of the polygon. Make *HJ* twice the height of *HG*, and *KL* three times *CD*. Join *JK* and *JL*. Then *JKL* is one triangle equal in area to the polygon. Other triangles may be drawn equal in area.

358. In a Given Circle to Inscribe a Rectangle of a Given Area. Draw any diameter *BD*, and from the centre *E* draw *EF* perpendicular to *BD*, making *EF* such a length that *EF* × *ED* is one half the given area. Through *F* draw *AG* parallel to *BD* and cutting the circle in *A* and *G*. Join either of these points,



CONSTRUCTION OF AREAS EQUAL TO AND PROPORTIONAL TO OTHERS say *A*, to *B* and *D*. Through *E* draw *AC*, cutting the circle in *C*. Join *BC* and *CD*. Then *ABCD* is the rectangle required.

359. To Construct a Triangle Equal in Area to the Sum of Two Given Triangles *ABC* and *CED*. Place them so that a side *CB* of one is in the same line as a side *CE* of the other, and a corner *C* adjacent with a corner *C* of the other. Join *BD*, and through *E* draw *EF* parallel to *BD* and cutting *CD* in *F*. Through *F* draw *FG* parallel to *CB* and cutting *AB* produced in *G*. Join *CG*, and *AGC* is the triangle.

Proportional Division of Areas.

360. To Bisect any Irregular Quadrilateral Figure *ABCD* by a Straight Line Drawn Through One of its Corners *C*. Draw the diagonals *AC* and *BD*. Bisect *BD* (the diagonal opposite the given point *C*) in *E*. Through *E* draw *EF* parallel to *AC*, cutting *AB* in *F*. Join *FC*, which bisects the figure.

361. To Bisect a Given Triangle *ABC* by a Line Parallel to One of its Sides. On either side, say *AC*, construct a semicircle, and at the centre *D* erect a perpendicular *DE* to *AC*. With *A* as centre and *AE* as radius describe an arc cutting *AC* in *F*. Through *F* draw *FG* parallel to *BC*. *FG* bisects the triangle *ABC*. The other construction shows how to divide the triangle into four equal parts.

362. To Bisect a Given Triangle *ABC* by a Line Perpendicular to One of its Sides, say *AB*. Bisect *AB* in *D*, and from *C* draw a perpendicular *CE* to *AB*, cutting it in *E*. Find *BF* the mean proportional to *BD* and *BE*. Set off *BG* equal to *BF*. From *G* draw a perpendicular *GH* to *AB*. *GH* bisects the triangle.

363. To Bisect a Triangle *ABC* by a Line Drawn Through a Given Point *D* in One of its Sides. Bisect *BC* in *E*, and join *AD*. Through *E* draw *EF* parallel to *AD*, cutting *AC* in *F*. Join *DF*, which bisects the triangle.

364. To Divide a Given Triangle *ABC* into Two Equal Parts by Lines Drawn Through any Given Point *D* within it. From the corner of the triangle nearest the point *D* draw a line *AE* bisecting the opposite side *BC* in *E*. Join *DE*, and through *A* draw *AF* parallel to *DE*, and cutting *BC* in *F*. Then the lines *DA* and *DF* bisect the triangle.

365. To Divide a Circle into any Number (say Three) of Parts Equal in Area and Perimeter. Draw a diameter *AB*, and divide it into the same number of equal parts as the circle is to be (three in this case). Describe semicircles on opposite sides as shown.

366. To Divide a Semicircle into any Number (say Three) of Equal Parts by Concentric Semicircles. Bisect the radius *DC* in *E*. With *E* as centre, and *EC* or *ED* as radius, describe a smaller semicircle. Divide *DC* into the same number of equal parts (in this case three) into which the given semicircle is to be divided, and erect the perpendiculars to *DC* from *F* and *G*, cutting the smaller semicircle in *H* and *J*. With *D* as centre, and *DH* and *DJ* as radii, describe the concentric semicircles which trisect the large given semicircle.

367. To Divide a Given Triangle *ABC* into any Number of Equal Parts (say Three). First, by Lines Drawn Through One of its Corners *A*. Divide *BC* (opposite *A*) into three equal parts in *D* and *E*. Join *AD* and *AE*, which trisect the given triangle.

368. The Same. But, Secondly, by Lines Drawn Through a Fixed Point *D* in One of the Sides. Divide *AB* (the side containing the given point *D*) into three equal parts in *E* and *F*. Join *D* to the opposite corner *C*, and draw *EG* and *FH* parallel to *DC*, cutting *AC* in *G* and *BC* in *H*. Join *DH* and *DG*, which trisect the given triangle.

369. The Same. But, Thirdly, by Lines Passing Through a Fixed Point *D* within the Given Triangle *ABC*. Divide one of the sides, say *BC*, into three equal parts in *E* and *F*. Join *AE* and *AF*. Also join *D* to *A* and *E*, and through *A* draw *AH* parallel to *DE*, cutting *BC* in *H*. Join *DH*, then *ABHD* is one of the required three equal parts. Next, join *D* to *F*, and through *A* draw *AG* parallel to *DF*, cutting *BC* produced in *G*. Join *DC*, and through *G* draw *GJ* parallel to *CD*, cutting *AC* in *J*. Join *DJ*, then *ADJ* and *DHCJ* are the other two required equal parts.

370. To Divide a Parallelogram *ABCD* into any Number of Equal Parts (say Three) by Lines Passing Through a Given Point *E* in One of the Sides. Divide *BC* into the required number (three) of equal parts in *F* and *G*. Draw *FH* and *GJ* parallel to *AB* or *CD*, and cutting *AD* in *H* and *J*. Bisect *FH* in *K*, and *GJ* in *L*. Through *K* and *L* draw *EM* and *EN*, cutting *AD* in *M* and *N* respectively. Then *EM* and *EN* trisect the given parallelogram.

371. To Divide a Given Parallelogram *ABCD* into any Number (say Five) of Equal Parts by Lines Drawn Through One of its Corners *A*. Divide each of two adjacent sides *DC* and *CB* into the same number (in this case five) of equal parts, into which the parallelogram is to be divided. Draw lines from *A* to 2 and 4 in *DC*, and to 2 and 4 in *BC*, and these lines divide the parallelogram into five equal parts. The same method may be used for dividing a square or oblong into equal or proportional parts.

372. To Bisect a Given Trapezium *ABCD* by a Line Drawn from One of its Corners *B*. Draw the diagonals *AC* and *BD*. Bisect *AC* in *E*, and draw *EF* parallel to *BD*, cutting *CD* in *F*. Join *BF*, which is the line of bisection.

Note. Problems 373—375 are explained in next lesson

STRENGTH AND METHODS OF TESTING

Stress and Strain. Strength of Timber. Stiffness. Resilience. Preparing Test Pieces. Testing Machine. Table of Timber Strength

By Professor HENRY ADAMS

Load, Stress, and Strain. The previous articles have dealt with the origin and general characteristics of the more commonly used materials, and the special property of resistance to stress and some other physical qualities will now be considered. Any load, however it may be applied to a body, induces a resistance which is called *stress*, and the alteration in form which is produced is called *strain*. There is, therefore, no load without stress, and no stress without strain. This will perhaps be more fully apprehended if the statement be amplified as follows: "By a load on any piece or member of a structure is meant the aggregate of all the external forces acting upon it, including the weight of the piece itself and of other pieces supported by it. By a strain is meant the change of form produced in a piece by the action of a load; and by a stress is meant the resistance set up in the material by its molecular forces opposing the action of a load in producing a strain. Thus a *load* of so many *pounds* upon a piece having so many *square inches area* produces a *stress* of so many *pounds per square inch*, the result being a *strain*, or change of form, of a certain amount, whether temporary or permanent, and, when large enough, appearing as stretching, shortening, bending, crumpling or twisting." The *strength* of a piece is measured by its power of resisting stress. The three chief kinds of stress are *tension*—stretching, pulling or tearing; *compression*—crushing, pushing or squeezing; *shearing*—cutting, nipping or sliding (called also *detrusion* when acting along the grain of wood). There are three other varieties, *transverse stress*—cross strain, bending, deflection, which is made up of tension and compression on opposite sides; *torsion*—twisting or wrenching, which is a variety of shearing; *buckling*—crumpling, corrugating, twisting, which merges into crushing when the length is short enough.

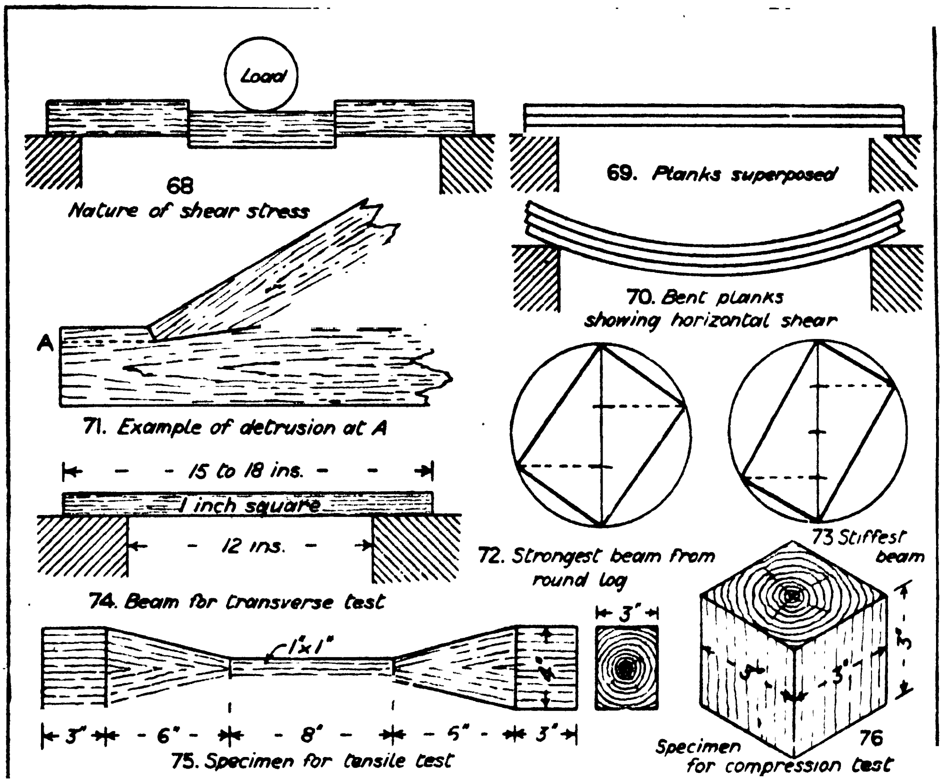
Tables of strength are available for a great variety of materials, the pieces being generally selected with the utmost care and every precaution taken to produce a high result. Applied to everyday practice these results give a false idea of the margin of safety between the working stress and the ultimate stress. When a factor of safety of, say, four is nominally allowed, the actual margin is seldom greater than two, and often less. Besides what may be called stress tests, there are ocular and other tests of quality, depending upon the nature of the material and the use to which it is proposed to be put.

Tension. The word tension is used to express the state or condition of a body when any forces acting upon it tend to pull any two portions asunder; it is then said to be in tension, or under tension. When either the stress or strain are referred to, the terms *tensile stress* and *tensile strain*, or *extension*, are used. The tensile strength of a piece is its ability to resist being pulled in two, and is measured by the pull in units of weight per unit of area necessary to cause rupture. When the material will break with moderate loads the units are generally pounds and square inches, but when heavy loads are required the units may be tons and square inches. In testing the majority of materials it is necessary to prepare the sample piece in a special form, varied with the kind of material, so that the fracture may take place within a certain limited distance near the centre, and so that the pull shall be in line with the axis of the piece. If the pull were not truly axial—*i.e.*, in the line passing through the centre of gravity of every transverse section—the stress caused would not be uniformly distributed, but would be greater on the side to which the line of pull was nearer, and less on the opposite side. The ultimate stress would thus be reached first on a small portion which would permit of rupture with a smaller total load, and this being divided over the sectional area would give a lower mean stress, and make the material appear to have less strength than it actually possesses. The ends of the pieces have also to be prepared in special shapes to suit the method of holding them while the force is applied, so as to avoid any interference with the reliability of the test. Although every means may be adopted to secure uniform results, it is very rare for any two samples of the same material, even when taken from the same piece and tested in the same machine by the same man, to give precisely the same figures, and therefore several samples should be tested before any average can be arrived at. It is also necessary to note the maximum and minimum results, the latter for use in calculations regarding the strength of structures, and the former in designing machines to overcome the strength, such, for instance, as punching and shearing machines.

Compression. This term expresses generally the opposite of tension, and hence we have *compressive stress* and *compressive strain*. The *compressive strength*, or resistance to crushing, is measured in the same units as before—viz., pounds per square inch or tons per square inch as the case may be. In compressive tests the pieces, whatever the material may be, are generally formed into simple cubes, or rectangular blocks, the size depending upon the material and the capacity of the machines. Fibrous, granular, and crystalline materials may crack before finally giving way, and other materials may bulge and flatten out with no particular point at which ultimate failure may be said to take place. When the length of a piece, between the points at which the force and resistance are applied, exceeds a certain limit according to the nature of the material, the result is not pure compression. There is, in addition, a tendency to bend, causing an increase in the compressive stress on one side and a reduction on the other. The ultimate strength in these cases is practically limited by the load at which incipient bending takes place, as a very small addition to the load will produce total failure. This load depends approximately upon the area of cross section compared with the length, or upon the area and the ratio between the length and least diameter or width, but more accurately upon the area and the ratio of the length to the least radius of gyration of the section. In other words, the disposition of the area of cross section as well as its magnitude must be taken into account, together with the length. The mode of finding the radius of gyration, moment of inertia, and modulus of section—all closely allied—will be explained further on.

Shearing. When a loaded beam is supported at the ends, there is a tendency to shear at every vertical section between the load and the supports—*i.e.*, to cut through a cross section at any point by the part next the load sliding downwards against the part next the support [68]. There is also a tendency to shear horizontally at any point in the depth. The latter may be illustrated by a number of planks laid one upon the other, the ends being supported [69], when an actual sliding will be seen to occur, even with their own weight [70]. Shearing stress also occurs when parts in tension are joined by rivets or bolts, the rivets or bolts tending to be cut across, called single shear when failure may occur by cutting through the section in one plane only, and double shear when the cutting must occur in two planes at the same time. This matter will be explained in greater detail under the head of STABILITY OF STRUCTURES.

Detrusion. A special case of shear stress occurs in timber when from the shape and position of the parts there is a tendency to push off a portion in the direction of the grain, as in the beam of a roof [71] where the foot of the principal rafter is stepped into it, and presses against it in such a manner as to cause a liability to push off the upper part along the dotted line. Failure is prevented by leaving sufficient length between the point of the principal rafter and the end of the tie-beam, the necessary amount varying with the kind of wood. Those woods that are very straight-grained and split easily require



DIAGRAMS RELATING TO STRENGTH OF TIMBER

more than those with an irregular or interlaced grain, particularly if the medullary rays in the latter are strongly marked.

Transverse Stress. A projecting beam fixed at one end and loaded at the other, or supported at both ends and loaded in the middle, or loaded and supported in any way that causes it to bend, is said to be under transverse stress, the fibres on the outside of the curve being in tension, and those on the inside of the curve in compression, while the intensity of each stress reduces towards the centre of the depth, or the centre of gravity of the section, at which point they both vanish. The layer where this occurs is called the *neutral layer*, and the same line in a cross section is called the *neutral axis* of the beam. There are also vertical and horizontal shearing stresses set up in the beam at the same time. The unit of transverse stress is called the *modulus of rupture*, and sometimes—rather indefinitely—the *strength modulus*. It is commonly supposed to be the same as the maximum fibre stress, but from various causes it is usually greater than this. It is eighteen times the load that, placed in the centre of a beam 1 in. square, and 1 ft. between the supports, will just suffice to break it.

Torsion. If a shaft or axle be supported, and one end fixed while an attempt be made to rotate it by a lever fixed on the other end, a *torsional stress* will be induced, and a *twist*, or *torsional strain*, will be caused. Line shafting in a machine-shop is always subject to torsion from the force applied to the driving pulley and the varying resistances due to the work done from the other pulleys. Torsion may be described as a *circular shear*. It does not occur to any marked extent in structural work, and then only as the result of bearing surfaces not being properly levelled.

Buckling. A deep web plate, or the top flange of a girder, or the flange of a stanchion under compression, tends to bend, or to yield, by taking a wavy form. This is frequently a very important matter, and apt to be overlooked. It occurs at a much lower stress than that due to the crushing of a short block of the same material, and requires special calculations, which will be dealt with later on.

Permanent Set. When a piece is put under stress, it changes shape—elongating, shortening, bulging, etc., which alteration may or may not disappear upon the removal of the exciting cause. Any change from the original dimensions that remains after the removal of the stress is called *permanent set*. There is no very precise limit, compared with the ultimate strength of the material, at which permanent set commences, but, approximately, it begins to be appreciable when the piece is loaded to half its ultimate capacity.

Elastic Limit. The *elastic limit*, or *limit of elasticity*, is the point up to which the change of length in a piece under test is sensibly proportional to the force applied, and from which the piece will return to its original dimensions when the force is removed. In other words, the elastic limit is the maximum stress per square inch sectional area which any material can undergo without receiving a visible permanent set. As the elastic limit is the highest stress that can be put upon any piece without causing actual damage to it, the *factor of safety* should be a ratio determined by the elastic limit rather than by the ultimate strength. Generally speaking, the working stress should not exceed half and the proof stress two-thirds of the elastic limit.

Modulus of Elasticity. The modulus of direct elasticity, or *stress-strain modulus*, known also by many other names, particularly that of *Young's modulus*, is the ratio obtained by experiment of the stress per unit of section to the strain per unit of length up to the limit of elasticity. It is fairly constant for each material within this limit, but beyond it the strain increases more rapidly than the stress. It was at first described as the height in feet to which a body would have to be piled in order that any small addition to its top, of its own substance, might compress the rest to an extent equal to the bulk of that added quantity. This is strictly Young's modulus, and is expressed in feet, but out of compliment to his memory his name is still associated with the present stress-strain modulus. An intermediate stage, which, however, is numerically equivalent to the present stress-strain modulus, was reached by Hooke, who defined the modulus of elasticity as the load which would increase a bar to twice its original length, assuming the elasticity to remain perfect so long.

The modulus of elasticity affects chiefly the extension of material under direct tensile stress, and shortening under direct compressive stress. It also affects the resistance to bending or deflection, which is made up of extension on one side and compression on the other. This modulus is used in calculations of the strength of struts where the maximum working or proof stress must be below the limit where a tendency to bend commences.

Fatigue of Materials. When repeatedly strained beyond their elastic limit, although well within their ultimate strength, certain materials, as wrought iron and mild steel, take an increasing permanent set, and ultimately break with a smaller load than a similar piece left in its original state, but if annealed before rupture takes place the elasticity will be renewed. This loss of strength, *being recoverable*, is termed *fatigue*. The number of repetitions in imposing the load without annealing that may take place before fracture depends upon the extent to which the elastic limit is surpassed. A similar fatigue is induced when alternations of stress take place, say, from tension to compression and vice versâ, although the elastic limit is not overpassed in either direction. The safe working stress has about the same extent of range in tons, whether the stress be varying in tension only, in compression only, or in tension and compression alternately, so that in the latter case with equal stresses in either direction each extreme would be only about half the maximum possible in either of the former cases.

Strength of Timber. The table on next page gives in a compact form a general view of the chief elements of the strength of timber and some other useful particulars.

The various figures given by published tables are included in the range of values shown, except where extreme differences from the general average showed a probability of error. The normal variations are chiefly caused by differences in the quality and the seasoning. The pieces are very carefully selected so as to be straight-grained and free from knots or other visible defects, and, unless otherwise stated, they are always tested in their seasoned state.

In testing the differences of strength between green or unseasoned timber and dry or seasoned timber, it appears that green timber has only about 80 per cent. of the initial strength of dry timber, but the former would shrink badly and decay rapidly. Too much seasoning, or desiccating, is apt to render some timber, as fir and pine, brittle ; other timber, as mahogany and beech, is rendered brittle by age.

Weight of Timber. The weight of most timber varies according to the part of the tree from which it is cut ; as a general rule, that cut from the top of a tree may be taken as about 3 to 5 per cent. lighter than that cut from the butt. The weight also varies according to whether the timber is green or seasoned ; generally the seasoning of wood reduces its weight by about 5 to 15 per cent.

The shrinkage of timber in width during the process of seasoning may be taken as about 2 to 5 per cent., while oak often shrinks as much as 8 per cent. The shrinkage of timber in length is so small that it is not worth considering.

Specific Gravity. Relative weight per unit of volume and specific gravity are interchangeable terms with some materials, such as iron; with other materials, such as wood, the specific gravity taken in the ordinary way would vary with the length of time the wood was immersed, but with such material as cement, the weight per unit of volume has no direct comparison with the specific gravity. In the first class of materials, and in the second if only a short time be allowed to elapse so that the material does not become soddened, the weight of a given volume, such as a cubic foot, will equal the product of the specific gravity into the weight of a cubic foot of pure water at standard temperature and pressure ; but in the third class the specific gravity of the mass as individual grains is taken, and the comparison just stated will not hold good. If a comparison of weight is required in this class, then the *relative density* must be taken. Relative density, sometimes called specific density, may be defined as the weight of a given volume or bulk compared with that of an equal volume of pure water.

77. COMBINED TRANSVERSE AND TENSILE TESTING MACHINE FOR TIMBER OR CAST IRON.

Stiffness of Timber. Stiffness is an important property of timber, and it may often be necessary to make a calculation of its resistance to bending rather than of its ultimate strength, as, for instance, in the case of fir joists to which a plaster ceiling is to be attached. The strongest beam that can be cut out of a circular log is shown in **72**, and the stiffest out of the same log is shown in **73**. In the former the diameter is divided into three equal parts and perpendiculars drawn as shown, while in the latter the diameter is divided into four equal parts. The proportion of depth to breadth in the strongest beam is $\sqrt{2}$ to 1, and in the stiffest $\sqrt{3}$ to 1. The actual strength and stiffness, of course, depend upon the particular timber.

Resilience of Timber. By resilience is meant the work performed in bending timber to its proof deflection, but some authors define it as the resistance to transverse impact ; others call it toughness.

STRENGTH OF TIMBER

COMPARISON OF VARIOUS TIMBERS

Test Pieces. The most usual test of timber is for transverse strength. Pieces are prepared, as in **74**, 1 in. square and 15 to 18 in. long, placed upon hard and firm supports 12 in. apart and loaded in the centre, or what is called loaded in the centre, which may be anything from a sharp V-edge to a round pin 3 in. diameter or a flat bar 1 in. wide. The variation in results is sometimes due to loose ideas as to what constitutes a central load. When larger test pieces than 1 in. square are used, such as 2 in. by 1 in., or 3 in. by 2 in., the deeper side is placed vertical, and the clear span is increased so that the load required to break them shall not be excessive.

The reduction to the standard value of 1 in. square and 1 ft. span is made by considering that the strength varies as $\frac{bd^2}{L}$ where b = breadth in inches, d = depth in inches, and L = span in feet. For tensile tests the pieces are shaped as in **75**, but may be larger, according to the capacity of the machine, frequently up to, say, 3 in. by 3 in. in the central part. The ends are held by cast-iron clips bolted together, and the taper is such that sufficient length shall be left to provide against detrusion without any sudden change in sectional area, which would at once form a weak spot.

For compression tests it is usual to take a cube of 2 or 3 in. side, as **76**, and press on the end grain, noting when splitting first occurs and when final crushing takes place. When the test piece is longer than its least width there is a reduction of strength, but it is not noticeable until the length exceeds about six times the least width. There are very few recorded tests of the resistance of timber across the grain, although it is a very important matter, frequently recurring in construction. For instance, when a timber beam rests on a post, the post will have a much greater working pressure per square inch of bearing area than will the beam, especially in fir, and it is necessary to spread the pressure on the beam by a hard wood corbel, in order to secure economy and efficiency; but it is mostly guesswork. Approximately timber will only bear half the load perpendicular to the grain that it will bear in the direction of the grain.

Testing Machines. Messrs. W. & T. Avery, Ltd., make a very compact and handy testing machine for transverse tests up to 40 cwt. and tensile tests up to 60 cwt. [**77**]. It may be used for ascertaining the transverse breaking strength and deflection of any material up to cast-iron bars 2 in. by 1 in. in section and 36 in. clear span, and in tension up to cast-iron specimens ½ in diameter. The bed plate is of cast iron, fitted with dogs for holding the specimens adjustable to suit different lengths of bars, the base being graduated so that the specimens may be accurately positioned, either 12 in, 24 in., or 36 in. between centres. A graduated deflection scale is attached to the machine, by means of which the varying deflections of a specimen under different strains can be ascertained at any period of the test. The scale has two series of graduations, one decimally by $\frac{1}{10}$th in. divisions up to 1 in., and the other by $\frac{1}{16}$ divisions up to 1 in. A cast-iron standard is bolted to the base plate, fitted with hardened steel bearing blocks upon which the fulcra knife-edges of the steelyard rest. It has a strong wrought-iron steelyard, machined and polished bright, fitted with hardened steel knife-edges, and graduated up to the full capacity of the machine, thus dispensing entirely with loose weights. The steelyard is provided with a sliding poise, by means of which the steelyard is kept in equilibrium and the strain indicated. To ensure the strain being steadily and evenly applied, and the most accurate results attained, a small hand-wheel is fitted to the poise for propelling the latter. The strain is applied by actuating a turned and polished hand-wheel, with a screw working through a steeled and hardened stirrup, which exerts the strain on to the specimen. To minimise the shock on the steelyard due to the breaking of the specimen, a spring buffer is fitted to the steelyard carrier. For tensile and compressive tests of wrought iron and steel, larger machines are generally used, which will be described in connection with the testing of metals.

STOCKS AND SHARES

Capital. Dividends. Consols. Preference and Debenture Stocks. Brokerage. Stock-Jobbing. Problems. Powers and Roots

By HERBERT J. ALLPORT, M.A.

182. The cash necessary to carry on a business is called its *Capital*.

In some businesses, such as railways, waterworks, gasworks, etc., the capital required is too large to be supplied by one person. Let us suppose a new railway is to be made. The originators, or *Promoters*, of the scheme, issue a *Prospectus* explaining it, and stating the Capital required. This capital is divided into *Shares* of some fixed amount, such as £100, £20, £1, and members of the general public are asked to *apply* for shares. If enough applications are received to enable the promoters to go on with the undertaking, they *allot* shares to the applicants, and thus obtain the capital required. The persons who hold the shares are called the *Company*. The profits of the company in each year are divided among the shareholders in proportion to the face value of their shares. The money thus divided is called the *Dividend*.

A shareholder who wishes to retire from the company cannot obtain from it the money which he subscribed, but he may sell his shares. The amount he obtains for them will probably not be the same as the amount he originally subscribed: it will depend chiefly on the profits which the company makes.

183. The capital of a company is often called *Stock*. When the capital is called *stock*, a shareholder may sell *any quantity*, excluding fractions of a penny. For instance, a person holding £100 stock, may, if he pleases, sell £42 4s. 6d. stock.

But, if the capital is called *shares* he may only sell a complete number of shares. He cannot sell *part* of a share.

184. It is of the greatest importance the student should understand that "£100 stock" means "that amount of stock for which £100 was originally subscribed." It does *not* mean "that amount of stock which will *sell* for £100."

If £100 stock will sell for £100 cash, it is said to be *at par*. If it sells for *more* than £100 cash, say £108, it is said to be *at a premium of 8 per cent.*, or 8 *above par*. If it sells for *less* than £100 cash, say £97, it is said to be *at a discount of* 3 *per cent.*, or 3 *below par*.

185. In the case of public companies, we have seen that the dividend varies with the profits of the company. There is another sort of stock in which the dividend obtained from £100 stock is always the same. The Government of a country borrows money, for war expenses, and other purposes. The corporations of towns borrow money. Public companies borrow. In all these cases, a fixed interest is paid per annum on each £100 stock. A great portion of the British National Debt consists of the "Consolidated Annuities," abbreviated into "Consols," so called, because they were formed by consolidating several debts, contracted under various conditions, into one stock.

When a company borrows money at a fixed rate, it is often arranged that the interest on this new stock shall be paid before any dividend is paid on the original stock. The new stock is called *Preference* stock, and the old is called *Ordinary*. *Debenture* stock also receives a dividend before ordinary stock.

186. Stocks and shares are usually bought and sold through an agent called a *Stockbroker*. The charge which a broker makes for his services is called *brokerage*. In the case of Government stocks the brokerage is usually "⅛ per cent.," *i.e.*, 2s. 6d. on each £100 stock. The broker acts as the agent between the buyer or seller and the *Stock-jobber*, who deals in stocks and shares.

As an example, consider the following: On Monday, November 20th, Consols were quoted as "88⅞ to 89." This means that the jobber is ready to buy £100 of Consols for £88⅞ or to sell £100 of Consols for £89. Suppose then, a person, A, wishes to dispose of £100 Consols. A goes to his broker. The broker seeks out a jobber, who pays £88⅞ for the stock. The broker deducts £⅛, and hands over the remaining £88¾ to A. Next, if another person, B, wishes to buy £100 Consols, he goes to *his* broker. B's broker then finds the jobber, who now receives £89 for the stock; but B pays £89⅛ for it, since the broker requires £⅛.

A's Broker receives £⅛ from A		B's Broker receives £⅛ from B
A	Jobber	B
Receives £88⅞ from jobber, and pays broker £⅛. Thus clears £88¾	Pays A £88⅞. Receives from B £89	Pays £89 to jobber and £⅛ to broker. Pays £89⅛ in all.

Hence, in examples where brokerage has to be reckoned, the brokerage is added to the price when stock is bought, and subtracted when stock is sold.

It will be noticed that the broker's profit is certain. The jobber's profit, of course, depends on the difference between the buying price and selling price. Moreover, the jobber does not always manage to sell stock immediately after buying it, as was assumed in the above illustration.

187. We shall now work out various examples in stocks and shares. All questions in stocks depend on the principles of Proportion. The student ought to find no difficulties if he remembers that:

(1) £ s. d. *in* a company is *Stock*.
(2) £ s. d. to be *sold out* is *Stock*.
(3) £ s. d. to be *invested* is *Cash*.
(4) Brokerage is not reckoned unless specially mentioned in the question.

Example 1. I invest £4653 in $2\frac{1}{2}$ per cent. Consols at 94. How much stock do I get, and what is my income?

Here, we are told that £94 will buy £100 stock, and we have to find how much stock £4653 will buy.

$$\therefore £94 : £4653 :: £100 \text{ stock} : \text{Required stock}.$$

$$\text{Required stock} = £\frac{100 \times 4653}{94} = \underline{£4950\ \textit{Ans.}}$$

Again, we know that £100 stock gives an income of $£2\frac{1}{2}$. We have to find what income £4950 stock will give.

$$\therefore £100 : £4950 :: £2\tfrac{1}{2} : \text{Income}.$$

$$\therefore \text{Income} = £\frac{4950 \times 5}{100 \times 2} = \underline{£123\ 15\text{s.}\ \textit{Ans.}}$$

Or, in finding the income, we may work with cash instead of stock. For we know that by investing £94 an income of $£2\frac{1}{2}$ is obtained, and we are required to find what income is obtained by investing £4653.

Example 2. If I invest in 6 per cent. stock at 140, what percentage do I get on my money?

We have to find what income £100 will produce, if £140 gives an income of £6.

Hence,

$$£140 : £100 :: £6 : \text{Required percentage}.$$

$$\therefore \text{Percentage} = \frac{600}{140} = \underline{4\tfrac{2}{7}\ \textit{Ans.}}$$

Example 3. Which is the better investment, 3 per cents. at 98, or $3\frac{1}{2}$ per cents. at 115?

We may either, as in Example 2, find the actual percentage in each case; or, we may proceed as follows:

In the first stock, an investment of £98 produces £3 income. By proportion, we find that the amount which must be invested to produce $£3\frac{1}{2}$ is

$$\frac{£98 \times 3\frac{1}{2}}{3} = \frac{343}{3} = £114\tfrac{1}{3}.$$

But the second stock requires an investment of a greater sum, viz., £115, to produce this income of $£3\frac{1}{2}$. Therefore, the 3 per cent. stock is the better investment.

Example 4. A man sells out £5,000 from the $2\frac{1}{2}$ per cent. Consols at $85\frac{1}{8}$ (brokerage $\frac{1}{8}$) and invests the proceeds in $6\frac{1}{2}$ per cent. railway shares at $165\frac{1}{2}$ (brokerage $\frac{1}{4}$). Find the change in his income.

His income from Consols $= 50 \times £2\frac{1}{2} = £125$.

He sells £100 Consols for $85\frac{1}{8} - \frac{1}{8}$, *i.e.*, £85.

Therefore, he sells £5,000 Consols for $50 \times £85$.

Next, to obtain $£6\frac{1}{2}$ income from railway shares, he has to invest $£(165\frac{1}{2} + \frac{1}{4})$, *i.e.*, $£165\frac{3}{4}$. We find, by proportion, what income he will get by investing $50 \times £85$.

Thus,

$$165\tfrac{3}{4} : 50 \times 85 :: £6\tfrac{1}{2} : \text{Income}.$$

Hence, his new income

$$= £\frac{6\frac{1}{2} \times 50 \times 85}{165\frac{3}{4}} = \frac{\cancel{13} \times 50 \times \overset{5}{\cancel{85}} \times \overset{2}{\cancel{4}}}{\cancel{2} \times \underset{\underset{3}{\cancel{51}}}{\cancel{663}}}$$

$$= £\frac{500}{3} = £166\ 13\text{s.}\ 4\text{d.}$$

Therefore, the new investment increases his income by £166 13s. 4d. − £125 = £41 13s. 4d. *Ans.*

Note, that in examples of this sort, it is not necessary to find *the amount of stock* he obtains by the new investment.

Example 5. A man invested his money in railway stock which yielded a dividend of $6\frac{1}{2}$ per cent. the first year, and he paid 1s. in the £ income-tax. The next year the dividend was 6 per cent., and the income-tax was 10d. His net income was thus reduced by £119. How much stock had he?

Income-tax at 1s. on $£6\frac{1}{2} = 6\frac{1}{2}$s.

∴ In the first year, each £100 stock gives a net income of £6 10s. − 6s. 6d. = £6 3s. 6d.

Income-tax at 10d. on £6 = 5s.

∴ In the second year, each £100 stock gives a net income of £6 − 5s. = £5 15s.

Hence, his income from each £100 stock is reduced by £6 3s. 6d. − £5 15s., or 8s. 6d.

But the total reduction is £119, and we find by proportion what amount of stock this represents.

Thus,

$$8\text{s. }6\text{d.} : £119 :: £100 \text{ stock} : \text{Required amount}.$$

Whence, amount of stock

$$£\frac{100 \times 119 \times 2 \times 20}{17} = \underline{£28000\ \textit{Ans.}}$$

Example 6. A man invests £22000, partly in 3 per cent. stock at 88, and partly in $4\frac{1}{2}$ per cent. stock at 110. He finds that on the whole he gets $3\frac{1}{2}$ per cent. for his money. How much is invested in the $4\frac{1}{2}$ per cents?

His income $= 220 \times £3\frac{1}{2} = £770$.

If all his money was invested in the 3 per cents. his income would be

$$£\frac{22000 \times 3}{88} = £750.$$

This is £20 less than his actual income.

The L.C.M. of 88 and 110 is 440. If £440 is invested in the 3 per cents. it gives an income of $5 \times £3 = £15$. If £440 is invested in the $4\frac{1}{2}$ per cents., it gives an income of $4 \times £4\frac{1}{2} = £18$. That is, by investing £440 in the $4\frac{1}{2}$ per cents. instead of in the 3 per cents., he increases his income by £18 − £15 = £3. We have only to find how much he must transfer to the $4\frac{1}{2}$ per cents. to increase his income by £20.

Thus,

$$3 : 20 :: £440 : \text{Required Ans.}$$

∴ Amount invested in $4\frac{1}{2}$ per cents.

$$= £\frac{440 \times 20}{3} = £\frac{8800}{3}$$

$$= \underline{£2933\ 6\text{s.}\ 8\text{d.}\ \textit{Ans.}}$$

NOTE. If we had been required to find the amount of *stock* in the 4½ per cents., we should simply have had to use £400 stock, instead of £440 cash, for the third term of the proportion.

EXAMPLES 17

1. How much must be invested in 4¾ per cent. stock at 102 to obtain an income of £380 ?

2. A man sells out £9400 of 2½ per cent. Consols at 90, and invests the proceeds in a 4 per cent. stock. He thus increases his income by £5. What was the price of the 4 per cents. ?

3. How much must be invested in 3½ per cent. stock at 115⅝ (brokerage ⅛) to give an income equal to that obtained from £5775 stock in 3 per cents. at 99 ?

4. A man invests in a 5 per cent. stock. After paying an income tax of 1s. in the £, he finds he gets 3¾ per cent. on his money. At what price did he buy the stock ?

5. A man invests half his capital in 3¾ per cent. stock at 90, and the rest in 4½ per cents. He obtains the same income from each investment. What is the price of the 4½ per cents. ?

6. By investing a certain sum in the 3½ per cents. at 98, my annual income is £15 more than if I had invested in 3 per cents. at 90. What sum did I invest ?

7. A person has £8225 in a 3½ per cent. stock. He sells out as much of it, at 102, as will produce £4131, and invests the proceeds in 5¼ per cents. at 119. Find the change in his income.

8. A man invests £2500, some of it in 3¼ per cents. at 103⅓, and the rest in 4 per cents. at 140. On the whole, he gets 3 per cent. interest on his money. How much of each stock does he buy ?

Answers to Arithmetic

EXAMPLES 16

1. £441 12s. 6d.

2. Interest = £980 – £875 = £105. Interest on £875 for 3 years at 1 per cent. = £26·25. ∴ Required rate = £105 ÷ £26¼ = 4 per cent.

3. Interest on £100 for 8 years at 4½ per cent. = £36. Hence, the proportion is £36 : £183 3s. : : £100 : Required sum. This gives £508 15s. *Ans.*

4. At 4 per cent., the interest on £100 will have amounted to £100 in 100 ÷ 4 = 25 years *Ans.*

5. £1691 4s. 10d.

6. See Art. **126**. Then, working in a similar way to Art. **125**, we get the required interest = £4 15s. 11·98d. = £4 16s.

7. £212 10s.

8. By method of Art. **128, Ex. 2**, the present worth is found to be £1250. Hence, the true discount is £1447 0s. 7½d. – £1250 = £197 0s. 7½d.

9. See Art **131**. Amount of bill = £816 13s. 4d.

10. Bill is due on August 7th. On March 14th it still has 17 + 30 + 31 + 30 + 31 + 7 = 146 days to run. Banker's discount is, therefore, the interest on £400 for ⅖ year at 5 per cent. = £8. The holder of the bill receives £400 – £8 = £392.

POWERS AND ROOTS

138. When a product consists of the same factor repeated any number of times it is called a *power* of that factor.

Thus,

7 × 7 is the *second power*, or the *square* of 7.

7 × 7 × 7 is the *third power*, or the *cube* of 7.

Similarly, by taking four, five, six, etc., factors, we obtain the fourth, fifth, sixth, etc., powers.

A power of a number is generally expressed by writing the number only once, and placing after it, above the line, a small figure to show how many factors are to be taken. The small figure is called an *index*.

Thus,

$$7^2 = 49\ ;\ \ 7^3 = 343\ ;\ \ 7^4 = 2401.$$

139. A number is called the *square root* of its square. Since $7^2 = 49$, the square root of 49 is 7.

The symbol $\sqrt{\ }$ is used to denote the square root. This symbol was originally the letter *r*, and stood for *radix*, the Latin word for *root*.

The "square root of 49" is written $\sqrt{49}$.

Again, a number is called the *cube root* of its cube. $7^3 = 343$. Therefore, the cube root of 343 is 7.

The "cube root of 343" is written $\sqrt[3]{343}$.

Similarly, a number is the *fourth root* of its fourth power, the *fifth root* of its fifth power, and so on.

A *perfect square* is a number whose square root is a whole number. A *perfect cube* is a number whose cube root is a whole number.

THE PROPERTIES OF MATTER

The "Fundamental" Properties—so called. Universal Motion. The Kinetic Theory of Gases. Molecular Forces. Surface Tension

Continued from page 1144

By Dr. C. W. SALEEBY

"Fundamental" Properties of Matter. In previous chapters we have already had to note the most striking of the *physical* differences which may obtain in the case of matter that is *chemically* one and the same in each case. There is no better instance than that of water, already mentioned. But there is a very large number of other physical properties of very great importance, and each of these must be briefly considered. Before considering them, however, we must note the existence of certain properties of matter to which some reference has already been made. In the first place, there is *extension*, or magnitude, or the property of occupying space; in the second place, there is the property of *inertia*. [See page 312.] Then, again, there is the property of *attraction* between every particle of matter and every other particle that we call *gravity*, and have considered at length. We have also referred to the property which is called *impenetrability*—a rather stupid and misleading name. It does not mean that your tea cannot penetrate into a lump of sugar, but simply that where the particles of sugar are the particles of tea cannot also be. This character of matter was also referred to in our second chapter, and we showed how difficult it is to be consistent in our ideas on this point when we come to compare them with the new theory of matter. Only a few years ago it was possible to say that impenetrability is a self-evident property of matter, just as it seems self-evident that matter is that which occupies space; yet both extension and impenetrability, as properties of matter, are now undergoing grave criticism. The last of this group of properties of matter is *divisibility*, a word which explains itself. Here, again, we find ourselves in difficulties to-day. The physicist, for instance, may take a portion of water, and in theory may go on dividing it and dividing it until he reaches certain ultimate particles, which are still particles of water, but which, if further divided, would cease to be water. It is just at the point when this further division is undertaken that the domain of physics ends and the domain of chemistry begins. For when these molecules of water are broken up we get new objects of study (oxygen and hydrogen) which differ from water, not merely in physical state, but in their chemical nature.

Ultimate Divisibility of Matter. But we cannot run away from our difficulties in this fashion. As physicists we propose to study the properties of matter in general, and we assert that divisibility is such a property. Someone submits to us, let us say, a specimen of pure hydrogen; in theory we divide it and divide it until we reach its ultimate molecules, each of which consists of two atoms of hydrogen. [See CHEMISTRY.] Therefore, in theory, we divide the molecules into atoms, the smallest particles of matter, as we know it, that can exist. But in imagination we can conceive of the possibility of dividing even an atom; and, indeed, we now know that the atom is really a compound body made up of a number of electrons. It is believed that these electrons are absolutely the units of matter. But we have asserted that divisibility is a property of matter, are we not then entitled to declare that even electrons can be divided? However small we conceive an electron to be, yet it really has a material existence; we cannot conceive that a sufficiently delicate knife might not chop it in half; yet, as we already noted [page 313], it is more than doubtful whether the existence of the electron is a material existence at all; it is in all probability an electrical existence. In the last resort, therefore, we are compelled to abandon the assertion which has been so long maintained—that divisibility is a fundamental property of matter. We have not really added to our difficulties, however, but have simplified them. On the old view that divisibility is an essential property of matter, we were landed in alternate absurdities. On the one hand, we could not conceive of any particle of matter so small that it could not be divided, and yet if we imagined the process of division to go on for ever and ever we found ourselves in a difficulty just as great.

A Conundrum Solved. But it seems to the present writer quite clear that the new theory of matter has disposed of this old conundrum which has puzzled men's minds for centuries. It is true that matter, as we know it, has the property of divisibility, but when we reduce matter to its ultimate units we find that all our ordinary ideas are inapplicable. These ultimate units are found not to have any material existence at all, but to be manifestations of energy. Now, it is meaningless to talk of energy occupying space; it is meaningless to talk of energy being impenetrable; and it is still more meaningless to talk of energy being divisible, as if you could take a piece of energy in your hand and cut it in half. When, therefore, we come to study what have long been called the fundamental properties of matter, in the light of the work of the last ten—especially the last two—years, we find that these so-called fundamental properties are not fundamental, and that we reach a stage in our analysis of matter when they simply cease to have any meaning. One hesitates to use a word which has been employed by spiritualists and all sorts of spiritualistic quacks; but the fact is that, as a French observer has recently said, modern physics has accomplished the *de-materialisation* of matter, and having revealed it as something which is ultimately not material at all, has compelled us to modify all our old assertions as to what we used to call its fundamental properties.

We have spent much space on this subject here and in a previous lesson. The reader will find no reference to it in any ordinary text-book of physics, and may accuse us of not having a due sense of proportion; but the fact is that during the last year or two the fundamental notions of physics have undergone profound changes, and to ignore the consequences of these changes would simply be to ignore the most important and remarkable work that has been done in physics since the time of Newton.

Leaving now these exceedingly difficult and subtle questions, we may pass on to the consideration of other properties of matter which are of very great importance, but which fortunately are in many ways much easier to understand than those properties which we have already attempted to discuss. Let us simply content ourselves with the existence of molecules, using that word in the strict modern sense defined in the course on CHEMISTRY. On page 692 in that course we considered in a short paragraph the question of the actual size of molecules. Let us now pass on to consider the behaviour of molecules in general, not the behaviour of a molecule of water as distinguished from a molecule of, say, sulphuric acid—that would be more properly a chemical question; but here we are concerned with the behaviour which is common to all molecules, no matter what their chemical composition may be.

Nothing is at Rest. The first and most important fact, of the profoundest importance from every point of view—physical, chemical, and philosophical—is that all molecules are in movement. This is a fact upon which all students of the matter are agreed. In our previous chapters we have spoken of molar forces and properties; we have discussed motion and the laws of motion. As these words lie before you on the table they are at rest—the pages will not move unless something moves them; but if you could see the molecules of the pages you would find them to be all in active motion. Consider any mass of matter you please, such as a billiard-ball, and it may be at rest as a whole or in motion as a whole; these are molar rest and molar motion. But in all the matter that we know there is no such thing as molecular rest; there is nothing but incessant molecular motion. The molecules that go to make up the ivory of the billiard-ball are in incessant motion amongst themselves, no matter whether the billiard-ball, as a whole, is moving or at rest. Now, when we have completed our discussion of the properties of matter, we are going to consider the great subject of *heat*, and we shall find that this property, molecular movement, is of the very first importance in relation to the whole subject of heat. No one can possibly understand heat, or the great physical truths to which the study of heat has led us, without having a clear understanding that wherever there is matter, there is motion. Indeed, we shall not have proceeded far in our study of heat before we discover that what we call heat is none other than molecular motion.

Molecular Motion of Gases. First of all, let us consider matter in that physical state which we call gaseous. The molecules of a gas are in a state of much freer and more rapid motion then the molecules of a liquid or a solid. In a previous chapter we have discussed some aspects of the fact called fluid pressure. We have seen that those fluids known as gases always completely fill any space in which they may be enclosed. In this respect they differ profoundly from the fluids called liquids and from solids. It is believed, for the most excellent reasons of many kinds, that the characters of a gas, its pressure, the relation of its pressure to its temperature and its volume (previously described as Boyle's Law), and its behaviour in completely filling any space in which it is enclosed are consequences, one and all, of the molecular movement in the gas. We have to regard the molecules of every gas as rushing violently about in one direction and another, often striking one another or rebounding from the sides of any vessel that encloses them. We must beware, however, of forgetting Newton's law of motion. We must not conceive of the molecules of a gas as changing the direction of their motion at their own sweet will; they have to obey the law of inertia, and their movements and the course of the direction of their movements are determined by forces outside them. If a molecule of a gas moving onwards changes the direction of its motion, that is because it has collided with another molecule or with some solid body, such as the side of a vessel, or because some new force has been impressed upon it.

Molecular Motion and the Radiometer. Now, in a previous chapter, when we were discussing gravitation and the great discovery of radiation pressure, we referred to the radiometer of Sir William Crookes [page 938]. We saw that when heat is applied to the radiometer the delicately balanced vanes which lie in a partial vacuum inside the glass bulb begin to revolve, and it was asserted that this revolution was due to the fact that the remaining air inside the bulb is unequally heated, owing to the fact that one side of each vane is bright, whilst the other is blackened. The blackened side of each vane absorbs far more heat than the bright side, and so the molecules of gas that strike against the blackened sides are heated in a greater degree than those which strike the bright sides.

The effect of this heat—indeed, the very existence of this heat—imparted to the molecules consists in a more rapid molecular movement. The consequence is that as they rebound from the blackened sides of the vanes they acquire an additional speed, and since, according to Newton's law, action and reaction are equal and opposite, they, so to speak, kick the vane behind them as they leave it. The consequence is that the vanes are set into rapid movement, the bright side of the vane being the advancing side, since it is the black side that has been kicked, so to speak, by the heated molecules as they rebounded from it.

What the radiometer demonstrates, then, is, as we have already seen, not radiation pressure at all, but the molecular motion that occurs in every gas or mixture of gases, such as the air inside the radiometer.

Kinetic Theory of Gases. Now we must look further into this question of molecular motion in a gas. All the facts that physicists have observed have led them to frame what is known as the *kinetic theory of gases.* We need not define the word kinetic again, since the reader will remember its derivation from the Greek word implying movement. Now, the kinetic theory of gases asserts that the molecules of a gas are in constant movement, which is of the kind we defined in an earlier chapter as movement of translation—that is to say, not movement of rotation in one place, but movement, as a whole, from one place to another place. This movement of translation implies the possession of kinetic energy (a term already defined) by the molecules of the gas; and it is further asserted by this theory that the degree of this kinetic energy depends upon the amount of heat in the gas. Indeed, the amount of heat in the gas *is* the amount of kinetic energy of its molecules. In other words, the heat in the gas and the molecular motion of the gas are one and the same thing. Hence the total quantity of heat in a given mass of gas will consist of the sum of the kinetic energy of all the molecules that are contained in it. Further, the kinetic theory of gases helps us to understand the pressure of any gas or mixture of gases.

The Kinetic Theory and Gaseous Pressure. The pressure of a gas must be regarded as the consequence of the ceaseless bombardment of the surfaces which enclose that gas by its molecules. The pressure of the gas will vary, and indeed does vary, in accordance with this theory. [Compare Boyle's law, already referred to.] For instance, if we diminish the density of the gas—that is to say, the number of molecules in a given volume of it—we diminish its pressure. This must be so, simply because there are fewer molecules to exercise that bombardment of which we have spoken and upon which we have asserted the pressure of the gas to depend. Again, the pressure of the gas will diminish if we lower its temperature, and will increase if we raise its temperature. These facts are readily explained by the kinetic theory of gases, for when we lower the temperature of a gas we lessen the amount of heat in it—that is to say, we reduce the amount of molecular motion in it, or the amount of kinetic energy which its molecules possess; the pressure of the gas is reduced because the vigour of the bombardment is less. Similarly, when the temperature of the gas is raised there is more heat in it—that is to say, there is more molecular motion, more kinetic energy, a more vigorous bombardment, and therefore an increase of pressure.

Much attention has been paid to the actual speed with which the molecules of a gas move; it varies very widely in the case of different gases. At a temperature of 0° C. the average speed at which the molecules of hydrogen gas move is considerably more than 1 mile per second. The molecules of oxygen gas at the same temperature—molecules which, as the student on the course of CHEMISTRY will remember, have a mass 16 times greater than the molecules of hydrogen—have a speed one-fourth of that of the hydrogen molecules.

The "Free Path' of a Molecule. Now, we have stated that a molecule of hydrogen at the temperature of the freezing point of water would move considerably more than a mile in one second; but we must remember that it is surrounded by a host of other molecules with which it must often collide. Hence there arises this very interesting question. In any given gas, at any given temperature and pressure, what is the average actual distance through which a molecule can move before it strikes against another molecule and has its course changed? This average, or mean distance, is technically known as the *mean free path* of a molecule. Plainly, the more dense the gas be—that is to say, the more its molecules be crowded together—the shorter is the distance which the molecule can expect to travel in a straight line without, so to speak, bumping up against another molecule. Perhaps we may get a clear image of what must happen if we compare the conditions under which a skater can move in a crowded or a nearly empty skating rink. Now, it is stated that in the case of the molecules that go to form the gases of the air within the ordinary limits of the atmospheric pressure and temperature, the mean free path must be exceedingly short, amounting to perhaps about 1,000 times the incredibly minute diameter of a molecule. The number of collisions which any molecule must undergo in a second under such conditions must be almost immeasurable. If, however, we consider the molecules of the gases of the air that is present in the so-called vacuum of an ordinary incandescent electric lamp we find that the proportion of molecules to the space they occupy is so small that, were it not for striking against the glass itself, each molecule would have a mean free path of more than 30 ft.

No Cohesion in Gases. Now, let us consider the physical state of a gas and contrast it with the physical state of liquids and solids. If you move one end of a stick, the other end moves also, a most remarkable and wonderful fact, though it is such a common case that few of us have ever thought about it; but when we do come to think about it we see that there must be some intimate relation between the molecules of the stick, so that when one end of the stick is touched something is transmitted which compels the other end of the stick to move also. This property of the molecules of the stick we will call cohesion, and the first point to note *about the physical state of any gas is that its molecules have no cohesion. They are absolutely* independent of one another save for the fact that they are apt to interfere with one another by means of collisions; but it is evident that of cohesion—as the molecules of the stick have cohesion—they possess not a trace. In fact, then, the physical state of a gas, as compared with the physical state of a liquid or solid, is *relatively simple.* We have merely to conceive *of the gas as consisting of a number of independent molecules each possessed of energy of motion, or kinetic energy, in virtue of which it flies onwards in a straight line until it strikes* something which sets it on a new course in another straight line, and so on indefinitely. There is *no* cohesion between the molecules, and though we must believe that gravitation acts between them, there is nothing of what we shall soon learn to call *molecular attraction.*

Molecular Motion of Liquids. Now let us turn to consider the case of a liquid and the peculiarities of its physical state. Here, again, we may be absolutely certain that there is abundant molecular motion, and we must inquire into the differences between molecular motion in the case of a liquid and the case of a gas. But first of all let us notice a most important consideration, which will reappear when we come to consider the contrast between a liquid and a solid. We speak and think as if there were three states of matter—solid, liquid, and gaseous—the distinctions between them being absolute. But, of course, we cannot forget the fact that there are many solids, such as pitch, which pass by continuous stages from the solid to the liquid state. This, and many similar facts, together with our philosophical belief that Nature is not broken but continuous, and together with the conceptions which we must form as to what happens during the gradual process of evaporation of a liquid, or liquefaction of a gas or solidification of a liquid—all these considerations lead us to the very important conclusion that the transitions of ice, for instance, to the state of liquid water and then to the state of water vapour are absolutely continuous.

Transition from Solid to Gaseous. We are compelled to believe that all the stages between the solid and the gaseous state, which our reason compels us to assume, do really exist. The fact merely is that, as a rule, certain of these stages, such as the stages between ice and liquid water, are so rapidly passed through that unless very careful experiments are made for the purpose we fail to observe them. But the new science of physical chemistry has devoted much attention to this subject, and as the years go on we constantly become more and more certain that the so-called three states of matter represent not states that are absolutely distinct from one another, but states which are continuously connected by an unbroken series of gradations, certain of which happen to be very inconspicuous or so rapidly passed through that in the case of the majority of substances and under ordinary conditions we fail to observe them. Having insisted on this most important point, let us see what happens when a gas is liquefied Let us consider the most familiar instance which is that of water vapour or gaseous water.

Liquefaction of Water Vapour. The use of the two words gas and vapour is merely a matter of somewhat doubtful convenience, the word gas being applied to substances which are most familiar to us in the gaseous state, and the word vapour to substances in gaseous form which, however, are most familiar to us either as liquids or as solids. If, then, we consider the case of water vapour, we may ask what must happen when a given mass of water vapour is subjected to an increasing pressure? We will assume that the temperature remains the same, else our problem is complicated. As the water vapour is compressed, its molecules become crowded more and more together, until at last we may imagine that a point is reached when a certain number of molecules would become so crowded that the force called molecular attraction would be able to assert itself between them and their neighbours. The excellent illustration has been given of the case of some planet or comet conceived to be wandering through space in a free path. By chance it comes within a certain distance of some other body, such as the sun, and gravitational attraction asserts itself to such an extent that the wanderer loses its freedom of movement and is compelled to enter into a special relation with the attracting body—such, for instance, as the relation which the earth holds to the sun as she travels round him. Now, some thing like that happens when the water vapour we are considering is compressed beyond a certain point.

Molecular Attraction. In the case of a molecule here and a molecule there, and gradually in the case of more and more molecules, the force of molecular attraction, whatever that really may be, comes to assert itself, and a new state of affairs is gradually set up, in which the water vapour gradually loses the character of a gas and assumes the character of a liquid. We must thus believe that the molecules of a liquid have become entangled with each other in the same sense as the earth is entangled with the sun. Previously they were able to move in any direction, and had so much kinetic energy of their own that they could even fly upwards, notwithstanding the force of the earth's attraction. But now they have lost their momentum and have established a new relation with each other. Gradually the process of liquefaction continues, in accordance with the assertion we have already made that the transition from the gaseous to the liquid state is gradual and continuous. When the total volume of water vapour has been sufficiently reduced, we find that it is no longer water vapour, but liquid water. Exactly the same results as have been achieved by increasing the pressure without alteration of the temperature would also have been achieved by reducing the temperature—that is to say, by reducing the amount of kinetic energy in the molecules—even though we had not subjected the water vapour to any increase of pressure.

How, then, are we to conceive the physical state of a liquid, and what is the nature of the motion of its molecules? They are no longer moving in *free* paths, long or short; the force of molecular attraction has been asserted, and the molecules are probably moving in complicated orbits round each other at a speed which, though very great, is less than the speed at which they formerly moved when enjoying the complete mutual independence possessed by the molecules of a gas. Well indeed it would be if we could now explain the exact nature of this force which we call molecular attraction. Ultimately, no doubt, it will be shown to be an electrical phenomenon, but that time is not yet.

The Process of Freezing. Next we must consider what happens when the liquid water becomes solid. Precisely the same change of conditions as turned the water vapour into liquid water will, if made more marked, yield us ice in its place. The essential difference between the solid and the liquid states is that the solid is possessed of less molecular motion than the liquid, so that the forces of molecular attraction are enabled still further to assert themselves. Let us turn to the illustration from astronomy. What would happen at this moment if the kinetic energy of the earth in its orbit was reduced or completely removed? In the first instance gradually, by a sort of narrowing spiral, and in the second instance immediately, by motion in a straight line, it would fall into the sun. A process exactly parallel to this is what happens where, by abstracting heat from liquid water—heat being none other than a form of kinetic energy—we reduce the kinetic energy of its molecules to such an extent that molecular attraction asserts itself still further, and their orbital motion around one another ceases. The consequence will be that the molecules come closely together, so closely that they cohere, and if we move one end of the block of ice that is formed, the other end, in virtue of this cohesion, will move also.

Molecular Motion of Solids. Now, are we to regard the motion of the molecules in the solid so formed as having ceased? Most assuredly not. Though the kinetic energy of the molecules has been so much reduced that they can neither fly about independently of each other as in a gas, nor yet revolve in orbits round each other as in a liquid, yet some kinetic energy still remains to them. Much heat has been abstracted from the water, but by no means all. There are many colder things than ice, and all ice is not at the same temperature. Probably we must regard the molecular motion of such a solid as ice as consisting of a to-and-fro or vibratory motion of pairs or groups of molecules. Pray observe the use of the word groups. For consider what is really the physical state of ice, which consists of crystals. These crystals must consist, in their turn, of regularly arranged groups of molecules, harmoniously vibrating with one another. The precise manner of their vibration will determine, we must suppose, the shape and size and other characters of the crystals of ice or any other substance.

The Result of Solidification. It is scarcely necessary again to insist that, as in the previous case, the process of solidification is a gradual one—first one molecule and then another being so far deprived of its kinetic energy, as heat is abstracted from the mass, that it can no longer maintain its orbital motion. But suppose that the process has been completed and that the whole mass is now solid, and suppose that we continue the process of reducing the temperature, and thus remove still more energy of motion or kinetic energy from the molecules of the ice. The result will be that their vibrations or to-and-fro movements will become less extensive, and the ice will shrink or contract. It is the general rule that when a body is heated it expands, and that when it is cooled it contracts. These facts can readily be explained on the theory of molecular motion: as heat, kinetic energy, motion, continues to be removed from the ice, it continues to shrink more and more, thus showing that its volume—the very space it occupies—is determined, partly at any rate, by the motion of its molecules. What will happen next?

The Coldest Cold. Now this is a fascinating and most important question. Suppose that we go on abstracting heat or molecular motion from any body, we must ultimately reach a point when there is no more heat or molecular motion in it—that is to say, when its molecular motion has been absolutely abolished. Such a body, and such a body only, would be absolutely cold, being destitute of all heat or molecular motion. But the study of this great question must be deferred for the present, until we have made a further study of the facts of heat. For the present it will serve, perhaps, to keep alive the reader's interest in this subject if we say that the absolute zero of temperature has never yet been reached by anyone, and that it seems more than probable that the attempt to reduce any substance, even frozen hydrogen, to this ultimate depth of cold, must for ever fail. As to the aspects which matter would present if deprived of all its molecular motion no one will dare positively to say; but of this more anon.

Molecular Forces in Detail. Perhaps the reader may be apt to think that molecular forces, because they are displayed in exceedingly small bodies, can have no very great magnitude. But that would be a very great mistake. Let him consider, for instance, the strain to which steel is exposed in many of its industrial applications; let him consider the number of tons which a steel wire will support—yet what is it but molecular attraction that keeps together the molecules of steel, even though such a tremendous strain is put upon them, endeavouring to pull them apart? We must clearly understand that though molecular forces act only at very minute distances, yet within those distances their power is gigantic. Gravitation, which we so constantly think of as tremendously powerful, is almost a negligible quantity when it is pitted against molecular attraction. When a great weight is supported by a steel wire it is evident that, *if we consider any level in that wire, the molecular forces of that level are sufficient to more than counteract the weight*—that is to say, the expression of gravitation—of all the mass of wire below that level and of the body that hangs at the end of it. We have chosen solids for our illustrations because it is in them that the molecular forces are so powerful, but they are very far from being negligible in many liquids.

Surface Tension. Every reader is familiar with the fact that a tumbler may be filled with water so full that the surface of the water is visibly higher than the edge of the tumbler, yet the water does not run over; though, if the finger be applied to the edge of the tumbler and the *surface* of the water be thus broken, some of it will run over the edge of the glass at the point where the finger was applied. This fact is a familiar illustration of the result of molecular attraction as it exists at the surface of a liquid. The technical name for it is *surface tension*, and its power may be measured by measuring the force which can be applied in such a way as to cut the surface of a liquid, but which, in virtue of surface tension, fails to do so. A thoroughly well greased needle, very gently placed on a still surface of water, will form a groove for itself, and lie on it without sinking. Now, how are we to explain this fact of surface tension? Why does the surface of the liquid look as though it were covered with an elastic skin made of the same stuff as itself? The surface of the liquid is composed of a number of molecules, and these have the mutual relations which we have already described. Immediately above the free surface of the liquids, as in the case of the filled tumbler, there are innumerable molecules that constitute the various gases of the air. Now, if we consider any molecule of the liquid, we see that it is attached by, and held to, the other molecules that are around and below it, whereas, on the other hand, it is not at all attracted—or, at any rate, not in anything like the same degree—by the gaseous molecules that are above it.

Formation of Drops. This fact of surface tension explains not only the curved surface of water in a full tumbler, but also, for instance, the fact that when water slowly falls it does so in drops. The formation of these drops and their curved external surface depend upon the fact that all the molecules of the liquid are, so to speak, bound to one another, whilst no force from outside tends to counterbalance their mutual attractions. Hence the surface of the liquid takes the shape which has the smallest possible area. Gravitation to some extent complicates the matter, so that often the drop is not completely spherical, but bulges a little at its lowest point. This familiar fact of surface tension has its uses, for upon it depends the process of making shot, which is accomplished by allowing a quantity of molten lead to fall through a sieve from a height into water. Gravitation in this case is negligible, and as the drops of lead fall and cool they solidify in the spherical shape which is imposed upon them by surface tension.

Results of Surface Tension. The case of water whose free surface is in contact with air is a simple and familiar one, but the number of different conditions in which surface tension may display itself is endless. Take, for instance, the surface formed by the contact of a liquid and a solid. If the solid be flat and perfectly free from grease, the various surface tensions are such as not to prevent many liquids from spreading themselves out upon it, or, as we say, wetting it; but if we take such a liquid as mercury, the relations of surface tension between it and the air and a flat surface on which a drop of it may be placed are such that the drop retains its form, and does not wet the surface. Similarly, water will not wet the surface if that be greasy. Briefly, we may note one or two other facts of surface tension—such as, for instance, that a rise of temperature diminishes this force, this being precisely what the reader would expect if he recalls what has been said as to the effects of temperature, or, rather, amount of heat, upon the movements and relations of molecules. Lastly, we may refer to soap bubbles—bubbles which consist of thin films of soapy water arranged in bubble form under the influence of surface tension—that is to say, the relation between the molecules of the water and the soap in the mixture, and their greater attraction for one another as compared with their attraction for the gaseous molecules within and without the film which constitutes the soap bubble.

ENGLAND AND WALES

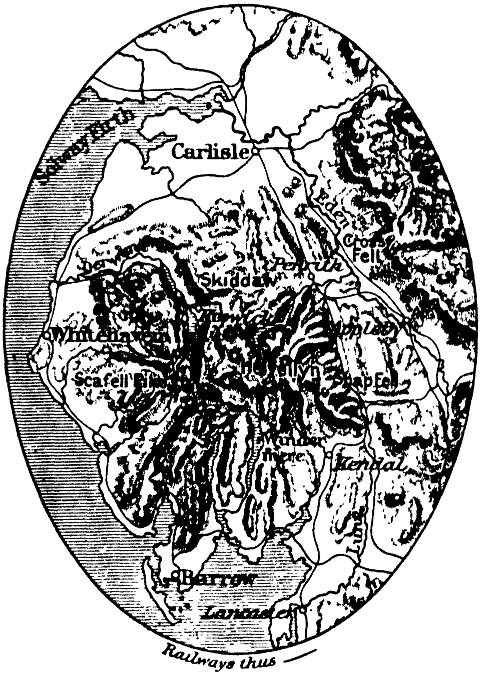
The Lake District. The Pennines. The Principal Coalfields. The Midlands. The Thames Basin and Estuary. The Severn. North and South Wales

Continued from page 1068

By Dr. A. J. HERBERTSON and F. D. HERBERTSON, B.A.

ENGLAND

The Lake District. Along the Scottish Border are the Cheviot Hills, the link between the Southern Uplands of Scotland and the Northern Uplands of England. Their rounded summits rise to 2,500 ft. To the south is the Eden Valley, with Carlisle, the centre of an agricultural district, controlling all routes north and south. The Shap Pass, about 1,000 ft., leads from the Eden to the Lune basin, and the plain of Lancashire. The Eden and Lune valleys almost separate the Cumbrian mountains of Cumberland and Westmorland from the Pennines proper, the Shap Fells uniting the two in the centre. The Lake District is a district of bare mountains, often with terrible precipices, and long valleys filled by beautiful lakes. Innumerable streams, fed by the constant heavy rains from the Atlantic, course down the mountain sides, leaping from crag to crag in the waterfalls for which the district is famous. Skiddaw, rising above Lake Derwentwater, Scafell, above Wastwater, and Helvellyn, near Ullswater, the grandest of the lakes, are all about 3,000 ft. high. The climate is too wet and cold and the soil too scanty for agriculture, but there is much sheep-farming. Summer brings thousands of tourists, who congregate at Keswick, on Derwentwater, and Ambleside, on Windermere, the largest of the lakes. Kendal, once famous for its woollens, still manufactures friezes, procuring its coal by canal from the Lancashire coalfield.



71. THE LAKE DISTRICT

The Pennines. The Pennines run from the Scottish Border far into Derbyshire, with lowlands on either side extending to the sea. They are separated from the Cheviots by the Tyne valley in the north, and are divided into two masses by the Aire valley in the centre. The scenery varies with the character of the rocks, and is most picturesque in the limestone. Much of the Pennines consists of hill pastures, diversified by heather moors, and mosses or bogs. The highest points—Cross Fell, Bow Fell, Whernside, and Ingleborough—all north of the Aire, are between 2,000 and 3,000 ft. The picturesque Peak District of Derbyshire to the south is just over 2,000 ft. Here the rock is limestone mixed with millstone grit, a name which explains itself. "The edges form wild, craggy cliffs, with deep river gorges winding far back into the heart of the plateau. The upper surface is covered with a considerable thickness of peat, through which bosses of grit project, which have been worn into wild and fantastic forms." In the limestone districts of the Peak are immense caves, numerous underground rivers and steep-walled dales, like Miller's Dale, near Buxton. Mineral springs occur at Buxton and Matlock in the Peak, at Harrogate and Ilkley in Yorkshire, and elsewhere in the Pennines.

The Marginal Coalfields of the Pennines. On either side of these lonely uplands are busy industrial regions, darkened by day by the smoke of mill chimneys, and lit up at night by the glare of blast furnaces, all fed by the coal which abounds on both flanks of the Pennines. The iron industry in all its many branches, including shipbuilding on the coast, is very general. Cotton, brought across the Atlantic to Liverpool, and, since the cutting of the Ship Canal, to Manchester, is manufactured on the South Lancashire coalfield. In the Yorkshire valleys opening from the eastern Pennines the woollen manufacture is important.

The Western Fields. The Cumberland coalfield extends along the sea from Maryport to Whitehaven, the workings round Workington being carried under the sea. To the south, in the rugged Furness district of North Lancashire, on the margin of the Lake District, the abundance of red hæmatite iron has created the town of Barrow, which, 50 years ago, before the invention of the Bessemer process, was a fishing village. Among its many iron industries are smelting, shipbuilding, and the manufacture of ordnance, some works being on Walney Island, off the coast. Barrow is a busy port, and has steamer services to Irish Sea ports.

The South Lancashire Fields. Lancashire is flat and sandy along the coast, but rises to over 2,000 ft. in the north and east. Except on the coalfield, which covers 400 sq. miles between the Ribble and the Mersey, it is pastoral in the uplands, and agricultural in the lowlands, raising potatoes and oats. Lancaster, the county town, is hampered as a port by the silting of the Lune estuary. Heysham and Fleetwood, on the shallow Morecambe Bay, are ports and packet stations. Blackpool and Southport, north and south of the Ribble estuary, are crowded seaside places. At the head of the Ribble estuary is Preston, with important docks, engineering works, and cotton mills. Its frequent horse and cattle sales indicate its position on the margin of the agricultural region. Crowded on the coalfield to the south, and engaged in manufacturing cotton or iron (machinery, railway plant, etc.), or both, are Clitheroe, Burnley, Blackburn, Bury, Bolton, St. Helens, Oldham, Warrington, and Manchester, with Stockport and Staleybridge over the Cheshire border. Manchester, the industrial capital of Northern England, is less a manufacturing centre than a market. Its rival is Liverpool, with Birkenhead, near the mouth of the Mersey estuary, the focus of transatlantic trade and passenger traffic. Both the Liverpool and Birkenhead sides of the estuary are lined with docks and warehouses, which receive not only cotton, but grain, tobacco, leather, live and dead meat, and whatever the Atlantic coasts of the New World have to send, in addition to produce from other parts of the world.

The Cheshire Plain and North Staffordshire Coalfield. The Cheshire plain, an extension of the Central English plain, opens a way between the Pennines and the Welsh mountains. Except on their margin, it is an undulating meadow region, noted for cattle and dairy produce, including Cheshire cheese. Coal crops out in the east on the Peak margin, where silk and cotton are manufactured round Macclesfield. Rock salt is worked round Northwich, Nantwich, and elsewhere. Coal becomes more abundant in North Staffordshire, where it supplies the pottery towns, Burslem, Hanley, Stoke-on-Trent, etc., all making earthenware and china.

Northumberland-Durham Coalfield. Both Northumberland and Durham are rugged in the west, where Cheviot sheep and Durham cattle are bred. In the valleys opening to the lowlands barley, wheat, beans, turnips, and potatoes are grown in the rich clayey loam. Fishing towns and ports for coasting traffic dot the coast. The chief river is the Tyne, with two head streams, North Tyne from the Cheviots, and South Tyne, which has cut a valley across the Pennines, followed by the line from Newcastle to Carlisle. At its estuary are the Tyne ports, Newcastle, Tynemouth, Jarrow, and South Shields, the outlet for the manufactures of the rich coalfield. These include iron in all branches, hemp and wire rope, glass, chemicals and pottery. Much coal is exported. Newcastle, with Gateshead on the opposite bank, is engaged in all these industries. At Elswick, a suburb, are the Armstrong ordnance works, where the most powerful guns are made. Sunderland and the Tyne ports, Stockton and Middlesbrough, are similarly engaged in working up the iron which abounds in the Cleveland Hills of North Yorkshire. The combination of cheap coal and iron is rapidly attracting shipbuilding away from the Thames, where freight makes both costly, and concentrating the industry on the Tyne and Tees. Darlington manufactures woollens and carpets, as well as iron and steel. In striking contrast to these smoky industrial towns is Durham, on a height above the Wear, with a glorious cathedral, and old-world streets and houses.

The York, Derby, and Nottingham Coalfield. The eastern slopes of the Pennines are drained by a series of parallel rivers, Swale, Ure, Nidd, Wharfe, Aire, and Calder, whose valleys gradually widen from narrow dales of wild beauty to broad and fertile lowlands. In these valleys, as in the Tweed basin, where the conditions are similar, the woollen manufacture has long been important. The wool was supplied by the hill pastures above, and the river was there to turn the mills. Now, especially in the Aire and Calder valleys, water power is replaced by steam. The Yorkshire coalfield, between the Aire and the Don, covers an area of 45 miles by 20. The chief woollen towns are Keighley, Leeds, Bradford, Huddersfield, Halifax, and Dewsbury. Linens are made at Leeds and Barnsley. Cutlery, electro-plate and hardware are made at Sheffield and Rotherham, near the borders of Derby and Nottingham. In these counties, both rich in coal, the Pennine landscape gradually gives place to that of the plain. On the Derbyshire field collieries disfigure many a lovely valley. Silk is manufactured round Chesterfield, and in Derby, where brewing is also important. On the Nottingham field the manufactures are lace and hosiery, both carried on at Nottingham, on a tributary of the Trent.

The Vale of York. The rivers named above unite to form the Ouse, the main stream of which flows across the rich Vale of York parallel to the base of the Pennines. From the east comes the Derwent, flowing between the Yorkshire Moors, rich in iron, and the Yorkshire Wolds. The Vale is very fertile, and both agriculture and dairy farming are important. It is dotted with prosperous market towns. York, on the Ouse, with remains of the Roman city and a magnificent cathedral, is the focus of the district, and the seat of an archbishopric. In the rugged east, the towns are found along the coast, which, as far as Flamborough Head, is high and picturesque, and dotted with seaside resorts, of which Whitby and Scarborough are the most popular. South of Flamborough Head the low district of Holderness grows fine crops of wheat, beans, and hay, while barley and turnips do better on the higher Wolds. On the Humber, the broad estuary of the Yorkshire Ouse and the Trent are Goole and Hull, both busy fishing and trading ports and shipbuilding centres. Hull, besides an enormous trade by sea with the chief ports of Western Europe, carries on a large number of flourishing industries. The proximity of the Dogger banks makes the fisheries important all along the coast.

The English Plain. We now pass from the uplands to the lowlands of England. In the north they are cloven by the Pennines into the Lancashire and Cheshire plain in the west, and the plain of Yorkshire on the east. South of the Pennines they extend from the base of the western mountains to the North Sea, broken by occasional lines of heights. Here the population is concentrated, densely on the coalfields, more sparsely in the agricultural districts. The plain, outside the coalfields, is dotted with numerous towns, many very ancient, sometimes with manufactures of some importance, but always the focus of the traffic, trade, and political life of the surrounding district. Before the days of railways many, like Birmingham, Coventry and Norwich, had a very intense local life, and a highly intellectual society. Now London attracts the best elements, and provincial life is correspondingly impoverished.

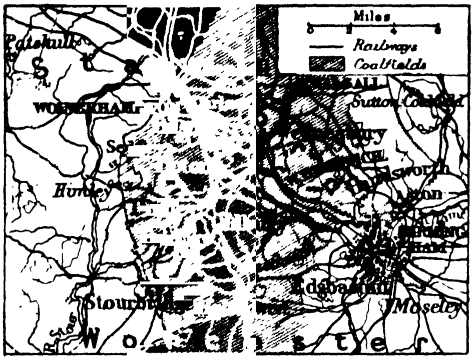
The Lincolnshire Fenlands. Lincolnshire occupies the angle between the Humber and the Wash. Much of it is a low plain, largely composed of fenland. Many canals and dykes have been cut to drain it, and along the sea it is often embanked to keep the sea out. In the centre the chalk, which covers much of southern England, crops out in the Lincolnshire Wolds, rounded hills with sheep pastures, and further west in the ridge of Lincoln Edge. Famous breeds of horses and cattle are kept in the rich, moist, low-lying meadows. Corn is largely grown.

Some Typical Towns. Lincoln, the county town, an ancient city with a fine cathedral, is built on a height, where the Witham cuts through the Lincoln Edge and becomes navigable. Its industries illustrate the relation of such a town to the district around. Its ironworks and manufactures of farming implements and machinery show how the needs of a farming country create local industries to supply them. Its steam flour mills and breweries show how agricultural produce is locally worked up. In spring, a horse and cattle fair lasts several days, and there are frequent corn, wool, and stock markets. This illustrates the distributing centre.

The Foss Dyke, from the Witham, near Lincoln, to the Trent, connects the counties of the Trent basin with Boston, on the Wash, at the mouth of the Witham, a fishing port, exporting grain, and - manufacturing sailcloth, leather, and ropes. Such industries, as well as boatbuilding, are found in almost every coast town. Fishing is important all along the coast. The chief market is Grimsby, near the mouth of the Humber, from which fish trains run to the inland towns. Grimsby trades chiefly with the North Sea and Baltic ports. Besides fish, it exports, among other things, cotton and rubber. These have been brought originally from African or American ports to Liverpool, worked up on the Lancashire coalfield, forwarded by the lines which cross the Pennines, and finally shipped from this East Coast port to the opposite shores of Europe. Of the imports, note butter, from the meadows of Denmark and Holland, and timber, from Scandinavia and the Baltic. The trade of Grimsby is thus an instructive commentary on its geographical position. The reader should similarly endeavour to think out for himself the actual or possible relations of his own district to the larger world without. A sub-port of Grimsby, collecting its exports and distributing its imports, is Gainsborough, on the Trent, an inland town on the map, but really built where the river is still tidal. Here Baltic timber is stored in timber-yards, or sawn in saw-mills, while other commodities are shifted from steamer to barge, or vice versâ, for the Trent is one of the great arteries of eastern England. It rises in the western Pennines, and flows round their base, receiving many tributaries, of which those from the Peak come down in lovely parallel dales and valleys. It is navigable as far as Burton, the famous brewing town, in the very heart of England, which is thus, by means of the Trent and the canals connected with it, brought into direct communication with the sea.

The Midlands. Under this term we may include the shires of Northampton, Rutland, Huntingdon, Bedford and Cambridge—drained to the Wash—Leicester and Stafford in the Trent basin, and Warwick in the Severn basin, the two latter containing the Midland coalfield. The east is the richest agricultural district of England. Of the rest much is in grass, forming ideal hunting country, hunted by many famous packs. It is separated from the Thames basin by the Cotswold and Chiltern Hills, with lower heights between. In the east the Welland, flowing past Stamford, the Nen, past the cathedral city of Peterborough, and the Great Ouse, past Bedford, St. Ives, and the cathedral town of Ely, all rising at no great elevation, flow sluggishly to the Wash. Much of their basins consists of marsh and fen land, reclaimed at great expense by cutting innumerable canals and trenches, or dykes, and forming a rich, black mould of great fertility. The so-called Isle of Ely, consisting of somewhat higher ground, was anciently entirely cut off by marshes, whence its name. It is now the centre of a fruit and vegetable growing district, with jam factories. Cambridge, on a tributary of the Ouse, is a university city with fine mediæval architecture. The basin of the Ouse contains some of the finest agricultural land in England, and wheat and other cereals are largely grown.

Associated industries are straw-plaiting, round Dunstable, in Bedfordshire, and brewing, which is very widely distributed. Dairy farming is almost as important. Stilton cheese is made near Melton Mowbray, in Leicestershire, and other associated industries are the fattening of cattle for the London market, and the boot and shoe industry of Northampton, Leicester, and Kettering. The very fine, long, staple wool of the Leicester sheep makes hosiery an important manufacture at Leicester. Outside the coal area, Warwickshire presents the same character. The county town is Warwick, with a famous castle on the Avon, near Leamington, with mineral springs, the ruined castle of Kenilworth, and Stratford, the birthplace of our national poet. As Shakespeare's country, it attracts many tourists. The cycle trade is important at Coventry. All these counties, with their park-like landscape, golden wheatfields, rich meadows, and ancient, somewhat sleepy towns, seem little changed by the coming of steam, and recall an England which has elsewhere largely disappeared.



72. THE BLACK COUNTRY

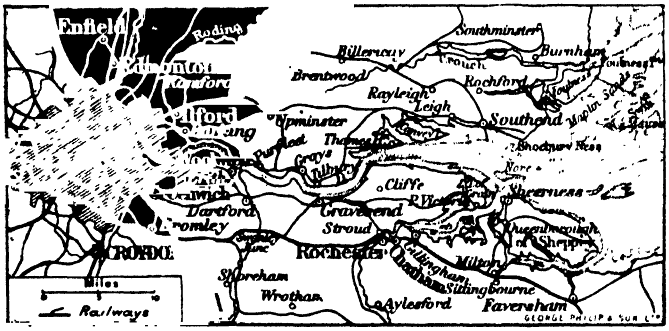
The Midland Coalfield. Very different is the scene on the coalfields of North Warwickshire and South Staffordshire. Vegetation is blasted, and a pall of smoke overhangs squalid towns of mean houses, little redeemed by the fine administrative buildings and the luxurious villas of the west end—the fashionable, because, with our prevailing west winds, the least smoky quarter. Though known under different names, the various collieries all form part of one extensive field. Iron is everywhere abundant, and so is the limestone required as a flux. Iron smelting and the iron manufacture in all its countless forms are carried on in a ring of iron towns rapidly growing into one unsightly whole—Birmingham, West Bromwich, Wednesbury, Walsall, Wolverhampton, Bilston, Tipton, and others—forming what is fitly called the Black Country.

East Anglia. East of the Midlands are the maritime counties of Norfolk and Suffolk, once part of East Anglia, with which we may include Essex outside the metropolitan area. All are, for the most part, flat, especially beside the sea, which encroaches on the land. Round the shallow Wash thousands of acres have been reclaimed. Beyond the Fen district, on the east coast of Norfolk, are the Broads, a region of shallow lakes and reedy marshes, teeming with wildfowl. Many rivers, rising in low heights to the west, flow east, opening to an estuary, with a port at the head, or mouth. Such are, among others, the Yare, with Yarmouth; the Orwell, with Ipswich; the Stour, with Harwich, the packet station for the Rhine and Elbe ports; the Colne, with Colchester. Similar in type, but called to a greater destiny, is the Thames, with London. The whole region is engaged in (1) agriculture, growing cereals and other crops, especially a fine malting barley; (2) grazing famous breeds of horses; (3) fishing, with its accompanying industries; and (4) the tourist industry, which is important all round the coast. The centres of the herring fishery are Yarmouth and the artificial port of Lowestoft. Of inland towns, note the cathedral city of Norwich, on a tributary of the Yare; and Chelmsford, on the Chelmer.

The Thames Basin. The Cotswold Hills, with lower heights to the north-east, separate the Thames from the Severn basin. They rise steeply from the western plain, exposing their bare limestone ribs, topped by short, dry pastures on which sheep are kept, and slope gradually to the south-west. The main stream of the Thames rises near Cheltenham, and receives the Cotswold streams, Windrush and Evenlode, from hilly pastoral districts, with small towns engaged in manufacturing the wool and skins they produce. Thus gloves are made at Woodstock, and blankets at Witney on the Windrush. Oxford is built where the Cherwell comes in, having risen in the Northamptonshire heights, and flowed almost due south. It is a famous university city of great antiquity and beauty. Beyond its confluence with the Thame, a few miles below Oxford, the Thames cuts through the chalk, separating the Chiltern Hills on the north-east from the Marlborough, or White Horse Downs, on the west. At Reading it receives the Kennet, which flows in a valley between the chalk heights of Wiltshire and Berkshire. After passing near Windsor, with its famous Royal castle, the Thames receives tributaries from the Chilterns to the north. Flowing northwards, across the North Downs to the south, come the Wey, Mole, and Medway, forming gaps through these heights, which are used by the railways to the south coasts. In the picturesque lower reaches, Hampton Court, Twickenham, and Kew are names familiar to Londoners. The houses grow more numerous, and the river widens, until at London Bridge it is nearly 800 feet wide.

London. London, like Oxford, or Ely, was built originally among defensive marshes, on higher, firmer ground, and like Glasgow, at the lowest point at which the river could be bridged. A little above it grew up the city of Westminster, round a much used ford. The two are now continuous, but have separate administrative bodies. To describe London would require many pages. Its claims to rank as a beautiful city are based on (1) St. Paul's, in the City of London, rising above the Thames, not far from the Tower, an ancient fortress and former Royal residence; (2) the group of buildings fronting the river at Westminster, including the ancient Abbey and the Houses of Parliament, to which will soon be added the palatial home of the County Council on the opposite bank; (3) a few fine streets opening west from Trafalgar Square, considered one of the finest sites in Europe; (4) the group of Royal parks in the fashionable west end. Beyond lies a wilderness of mean streets, extending miles in all directions. Beyond these again, on north, west, and south, are pleasant suburbs. London is one of the great ports and markets of the world, and one of its chief financial centres. It is also the centre of national and imperial government, and the heart of our world-wide empire.

The Thames Estuary. In central London, the banks of the river are embanked and planted with trees, forming pleasant promenades. East of these come wharves, warehouses, docks, and the factories engaged in the many industries of a great seaport. Woolwich, on the right bank of the estuary, where the river is nearly twice as broad as at London Bridge, has an immense arsenal. Gravesend is a busy river port. Queenborough, on Sheppey, once an island, is a packet station for the Rhine ports. Shoeburyness, on the opposite bank, is a station for artillery practice. Sheerness, on Sheppey, strongly fortified, has barracks, dockyards, and arsenals. Chatham, at the mouth of the Medway, forming with the cathedral city of Rochester a single town, is the naval arsenal. There are many cement and brick works in the neighbourhood. Further east are numerous seaside resorts, Whitstable, with oyster fisheries, Herne Bay, Margate, and Ramsgate. Beyond Ramsgate, the chalk cliffs continue intermittently round the south coast as far as Lyme Regis, on the border of Dorset and Devon.



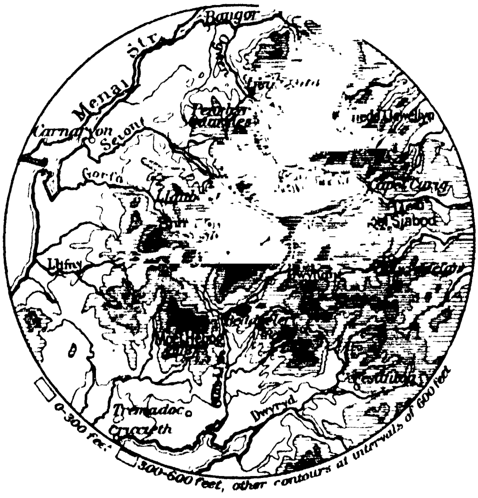
73. ESTUARY OF THE THAMES

The dotted area along the coast denotes the foreshore, which is uncovered at low water

The Channel Counties. Nearly all the towns just named are in Kent, often called the Garden of England. The Weald, formerly covered with forests between the North and South Downs, is very fertile. Cereals, fruit, and hops are grown. On the North Downs fine sheep are bred. Towns are numerous, both inland and on the coast. Maidstone, on the Medway, in the centre of the hop district, has important breweries. Canterbury, on the Stour, with a magnificent cathedral, is the ecclesiastical capital of England and seat of the chief archbishopric. On the coast are the ports of Deal, Dover, and Folkestone, the two latter Channel packet stations. Surrey, drained to the Thames by the Wey and Mole, which have cut gaps across the North Downs, has fine pinewood scenery. Sussex is drained to the Channel by short rivers cutting through the South Downs. Towns are numerous, especially on the coast. Notice Hastings, Eastbourne, the packet station of Newhaven, Brighton, and Worthing. Chichester, a cathedral city, is connected with the coast by a short canal. Hampshire, also a chalk county, is drained to the Channel by rivers flowing south from the Downs in the north. Note the indented coast, giving many good and two magnificent harbours. Portsmouth Harbour has an entrance 1½ miles wide, and is our chief naval base in the Channel. It is very strongly fortified. Portsmouth is the garrison town, Portsea the naval dockyard, Landport the artisan quarter, and Southsea a watering-place. On the opposite side of the harbour is Gosport. Portsmouth commands the entrance to Spithead, which, with the Solent, separates the mainland from the garden Isle of Wight, with the inland capital of Newport, and many summer resorts round the coast, including the yachting centre of Cowes. Both these straits open to Southampton Water, the Itchin estuary, with the great port of Southampton at its head. This is the packet station for most of our colonies and for the ports of the Indian, Pacific, and South Atlantic Oceans. The largest liners afloat can enter and leave at all states of the tide. Bournemouth, with pine woods, is a winter resort. Inland the chief town is Winchester, on the Itchin, with an ancient cathedral. It was originally the capital of England.

Dorset and Wiltshire. Dorset and Wiltshire form the south-western extremity of the chalk heights which cross the English lowlands. The rivers flow south, cutting gaps through the chalk heights. At most of these, towns are built, some, like the cathedral city of Salisbury, of great antiquity. These heights are known under many names, as, for example, Salisbury Plain, a moorland district on which is Stonehenge, an ancient stone circle. Grazing and dairy farming are important in the valleys, both Dorset and Wiltshire butter and bacon being famous. The sheep fed on the hill pastures supply wool for the woollen manufactures of Trowbridge, Bradford, and other towns, carried on with coal from the Bristol coalfields. Fishing and seaside towns line the coast, the most fashionable being Weymouth.

The West Country. Somerset is a transition county, resembling the Severn basin in the north, and in the Exmoor district passing into the scenery of Devon and Cornwall. It is a hilly county, with vales opening to the sea, the most fertile being the Vale of Taunton, famous for hops, fruit, and fine wheat. Bath is built on the gorge of the Avon, where excellent stone is quarried. Bristol, at the head of the Avon estuary, has long been a famous port. Early in our history it exported the wool of the surrounding sheep-farming counties, and supplied much of Catholic Europe with fish. The discovery of America increased its importance, and it now trades with every part of the world, especially across the Atlantic. Among its many manufactures are tobacco, cacao, sugar refining, all depending on its imports. Shipbuilding, engineering works, chemical works, and soap and glass making are among its other industries.



74. SNOWDONIA

The elevation of the land is shown by the tints. The darker the tint, the greater the elevation. The solid black shows the land over 3,000 feet

Devon and Cornwall. Devon and Cornwall are maritime counties. Much of the interior is high, bleak moorland, forming the highlands of Dartmoor (1,700 ft.), with hardy breeds of ponies, sheep, and cattle; Exmoor, where deer are still semi-wild; and Bodmin Moor. Round these centres woollen towns tend to grow up, as at Axminster, in South Devon, where carpets are made. Honiton, not far off, makes lace. In the steep-sided valleys opening from the highlands the red earth is very fertile. Dairy farms and orchards supply Devonshire cream and Devonshire cider. The rivers enter the sea by picturesque winding estuaries, each with its fishing town. Notice Barnstaple in North Devon, and in South Devon, Axmouth, Sidmouth, Exmouth on the Exe, with the cathedral city of Exeter, the capital of the West Country, higher up the river; Teignmouth, Dartmouth, and especially Plymouth, built where the Tamar estuary forms Plymouth Sound. With Stonehouse and Devonport, Plymouth ranks next to Portsmouth as a naval station, and rivals Southampton in its world-wide communications. It is strongly fortified. Other coast towns are Torquay, a winter resort on Tor Bay, opposite Brixham, the centre of the trawl fishery. Cornwall prospers mainly by its fisheries, including pilchard and mackerel, and its tourist traffic. The tin and copper mines famous in antiquity are now little worked, and many miners emigrate. The towns are chiefly on the coast. Falmouth Harbour, with Falmouth at the mouth, and Truro at the head, recalls Plymouth Sound. Penzance and St. Ives lie in the extreme south-west, and are centres of pilchard fishing. The Scilly Isles, 150 in number, but few inhabited, engage in fishing and in growing early vegetables and fruit.

The Severn Basin. The Severn rises in a small lake on Plynlimmon, in the heart of the Welsh Highlands, whose sheep pastures feed the woollen towns Newtown and Welshpool. Shrewsbury, commanding the route across Cheshire into North Wales, had one of the many castles built along the Welsh Border, or March, of which Ludlow, Monmouth, and Chepstow may also be mentioned. The Severn flows through a picturesque district, between the Shropshire and Stafford heights, where coal and iron are worked in Coalbrookdale, and some wool is manufactured, as at Kidderminster, and then enters a broad vale between the Malvern Hills and the Forest of Dean on the west, and the steep Cotswolds on the east. On the right bank picturesque tributaries descend from the Welsh Highlands. The Teme flows past Ludlow, and enters the Severn not far below the cathedral city of Worcester, with famous porcelain works. The Wye, from Plynlimmon, rivalling the Rhine in beauty, flows by the cathedral city of Hereford, in a hop and orchard country, Monmouth, Tintern, and Chepstow to the estuary, which the Usk, with Newport as its port, also enters. On the left bank sluggish streams cross the central plains from low heights which separate the Severn basin from those of the Trent and the Wash rivers. The Avon, the largest, flows by Warwick and Evesham, in a rich orchard country, to the Severn at Tewkesbury. Wool is manufactured in Stroud and other Cotswold towns, with coal from the Forest of Dean, which also supplies Worcester. Cheltenham has mineral springs and famous schools. Gloucester, at the head of tidal navigation, with a fine cathedral, is a port. The Severn Bridge, nearly a mile long, crosses the estuary at Sharpness, and further south a tunnel, 4½ miles long, carries the lines for Wales below the bed of the river.

WALES

Much of Wales consists of mountains over 2,000 ft. high, with the longer slope and longer rivers to the east, and the short slope and shorter rivers to the west. North Wales is higher, bleaker, more picturesque, and more thinly peopled than South Wales, where the lowlands are more extensive, and coal and iron are abundant.

North Wales. North Wales consists of the counties of Anglesey, Carnarvon, Denbigh, Flint, Merioneth, and Montgomery, nearly all rugged. In the north-west Snowdon rises to over 3,500 ft., with magnificent precipice, lake and valley scenery. The Conway valley, with Conway, and the fertile Vale of Clwyd, with Rhyl, open to the northern lowland. Between the two is Llandudno, crowded with visitors in summer. The lowland is broadest in the island of Anglesey, separated from the mainland by Menai Strait, crossed by a tubular bridge, with Bangor and Beaumaris on opposite sides of the strait. Holyhead, on Holy Island, west of Anglesey, is the mail-packet station for Ireland.

The Dee Valley. An important break in the mountains of North Wales is made by the Dee, which rises among mountains just under 3,000 ft., not far from Bala Lake, the largest in Wales. It opens to the Flint lowland, with the collieries of Ruabon and Wrexham, and leads to the English Border at Chester, not far from the head of the estuary, which commands the route to the English plain, and has been important since Roman times. Its ancient streets, with their covered arcades, and its mediæval walls and towers, preserve for us a typical Old English city.

The West Coast. Here we find the familiar occupations of fishing and the summer tourist industry carried on by Aberystwith, and many other towns, each at the mouth of a picturesque valley opening to the sea. The same type continues along the South Wales coast. Summer brings prosperity, the winter usually privation, and much loss of life in the south-westerly gales.

South Wales. South Wales consists of Cardigan, Pembroke, Carmarthen, Glamorgan, Brecknock, and Radnor. The highest parts are in Cardigan, where Plynlimmon separates the Severn and Wye from the rivers flowing east and south, and in Radnor and Brecknock, where the mountains rise to over 2,000 ft. On the west coast are Cardigan, at the mouth of the Teifi valley, and Fishguard, which trades with the opposite coast of Ireland, and will soon become an important packet station.

A broad lowland fringes the south coast, treeless in the west, where it fronts the Atlantic gales, but rich and fertile in the Vale of Glamorgan. The coast is deeply cut into bays, the finest harbour being Milford Haven, on which is Pembroke, with dockyards, and New Milford, whence the South Irish mail steamers start at present. Long, parallel valleys descend to the coast of the Bristol Channel; the Tawe, with Swansea; the Neath, with Neath; the Taff, with Cardiff, and others. In the west sheep-farming is the chief occupation, but in Glamorgan the valleys are alive with colliery and furnace. The South Wales coal is specially good for smelting and for steam coal, and immense quantities are exported, much for naval purposes, from Llanelly, Swansea, Cardiff, Barry, and smaller ports. Iron is abundant, but of poor quality, and the great ironworks of Merthyr Tydvil, and the copper works of Swansea, are largely fed by imported ore brought to the ports at the valley mouths.

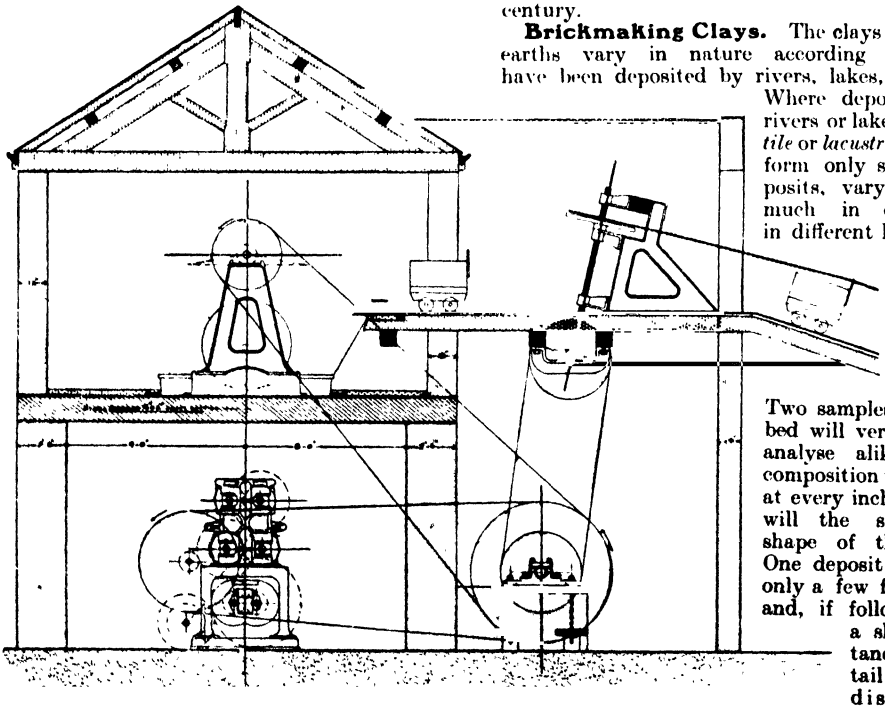
BRICKMAKING

Clays and Clay Deposits. Iron and Brick Colours. Brickmaking by Hand and Machine. Fire Clay and Fire Bricks

By CLAYTON BEADLE and HENRY P. STEVENS

THE origin of the art of brickmaking dates back to remote ages, and is, indeed, one of the very oldest of the crafts. Any plastic earth which can be moulded and sun-dried or baked may be made into a brick. In all probability the first bricks made were only sun dried, although among the earliest ruins of Egypt and Chaldæa may be found not only the sun-dried but also the properly burnt bricks. Herodotus tells us that the walls of Babylon were built of bricks made from clay dug from the trenches, and in Mesopotamia there are enormous mounds, all that remains of brick-built cities. If these bricks be examined it will be found that the outer layers are usually burnt bricks, while those on the inner side of the walls, where they would not be subject to the action of water, were made of sun-dried bricks. Many of these bricks were covered with stucco to protect them. Of course, sun-dried bricks were much more easily destroyed than those properly baked—indeed, we may read in ancient history that towns have been captured by invading armies who diverted a stream to run around the walls, which, being made of sun-dried bricks, were soon washed away. Although in Egypt most of the temples were built of granite or similar rocks, bricks were very much used for many of the buildings, and there still stand brick Pyramids, such as that of Sakkarah. The Biblical stories of the Children of Israel forced to make bricks are well known to all. These bricks seem to have been sun-dried bricks, and were moulded from material made by throwing cut straw, mud, and water into a pit and treading until sufficiently well "pugged."

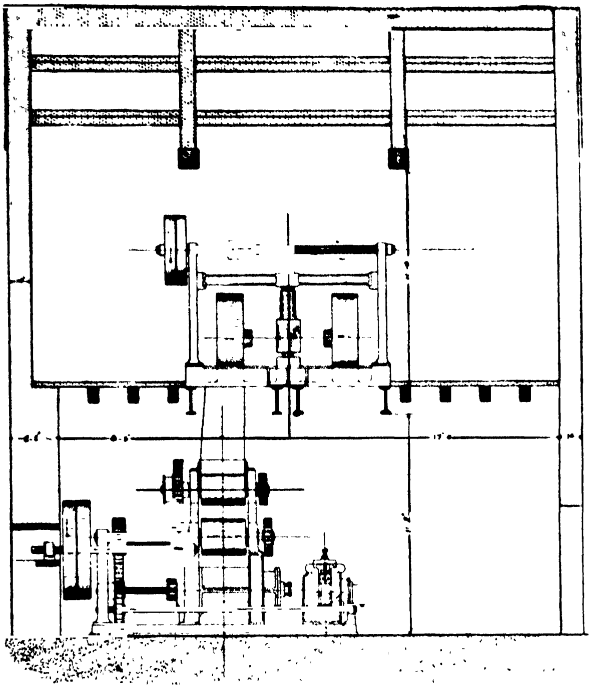
Another example of the use of a mixture of burnt and unburnt bricks is to be found in the Great Wall of China, and in Spain the sun-dried brick is often used at the present day. The Romans were probably the first to burn bricks in kilns, and the art seems to have been lost, at any rate in this country, as no trace of brick buildings is to be found between the time of the occupation of the Romans and the thirteenth century.



1. JOHNSON'S PLASTIC BRICKMAKING MACHINERY: LONGITUDINAL SECTION

Brickmaking Clays. The clays or brick earths vary in nature according as they have been deposited by rivers, lakes, or seas. Where deposited by rivers or lakes (*fluviatile* or *lacustrine*), they form only small deposits, varying very much in character in different localities. Take, for instance, brickfields in any part of Surrey or Kent. Two samples from a bed will very seldom analyse alike; the composition will vary at every inch, and so will the size and shape of the beds. One deposit may be only a few feet deep and, if followed for a short distance, will tail off and disappear; while another, which is scarcely noticeable, will broaden out into a deep bed. The Reading brick clay area is an example of lacustrine deposit. The marine deposits are notable for their great depths and uniformity, brought about by the uniform and regular action of the sea.

The big clay deposit in the Midlands known as the Oxford clay, and so much used for bricks in the neighbourhood of Peterborough, is a marine deposit. Analyses of the clay, taken at varying depths, all show much the same figures, and the extension of this deposit, which crops up again in France, scarcely varies from that dug in England. It will be readily understood that the marine clays are treated for brickmaking on quite different lines from the South of England clays, which are of fluviatile or lacustrine origin—*i.e.*, deposited by the agency of rivers or lakes. In the former case, powerful plant and big machinery are employed. The clay varies so little that it may be taken out for brickmaking with the certainty that, once having secured the right conditions, it will always give the same excellent results. On the other hand, in the South of England small hand machinery is better adapted to work the deposits, which have to be dug and carefully mixed, so as to get the desirable consistency.

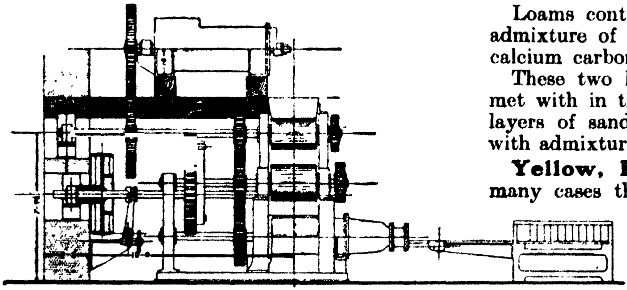


2. JOHNSON'S PLASTIC BRICKMAKING MACHINERY: TRANSVERSE SECTION

Classification of Clays. Clays can be roughly classified into plastic, or strong clays, loams, or mild clays, and marles, or calcareous clays.

In the first class, among the plastic, or strong clays, we may put the purer clays, although the purest of them all, kaolin, or china clay, is never so plastic as some of the others. The Oxford clay belongs to this type. It has, however, some disadvantages, as it contains much sulphur, in the form of iron pyrites.

In the course of burning the bricks, sulphurous fumes are given off in large quantity, and tend to bring about the formation of sulphuric acid. This has a tendency to *weather* out of the brick, causing the latter to go to pieces. The corrosive action of the sulphurous fumes is very noticeable in its effect on the chimney stacks which create the draught in the kilns. The acid attacks the mortar between the bricks, and in the Peterborough district the stacks are constantly under repair. We examined some bricks from within twenty feet of the top of a stack; they were intact, although the mortar was reduced to slime.



3. BRICKMAKING MACHINE FOR "WIRE-CUT" BRICKS

The strong class of clays are often improved by judicious admixture with other substances. Generally speaking, brickmaking clays are composed of other materials in addition to the silicate of alumina, or true clay substance. They contain oxides and phosphates of iron, and occasionally organic matter, iron pyrites, etc. The organic matter is the residue of the putrefaction of extinct vegetable and animal life.

Loams contain, besides the clay proper, an admixture of sand, while the marles contain calcium carbonate, or chalk.

These two latter clays are more commonly met with in the South of England, often thin layers of sand and clay occurring alternately with admixtures of the two.

Yellow, Red, and Blue Bricks. In many cases the colour of a brick affects the selling price more than anything else—especially where a brick is required for facing—with the result that colour often takes precedence to soundness.

Now, the whole range of colour in bricks is due almost entirely to iron, in some form or other. If a clay, consisting of more or less pure silicate of alumina, contains 1 per cent. or less of iron, the burnt brick will be white. As the proportion of iron increases, the colour will pass from yellow to orange, and then to red. With 5 or 6 per cent. of oxide of iron, a good deep red will be obtained. With larger proportions of iron, the colour is still deeper.

The colour is also better developed by stronger firing. If the brick will stand it, and there be enough iron, the colour of the brick will pass from red to blue, and even to brown or black. The Staffordshire blue bricks, so much used for engineering work, are well-known examples of the case in point.

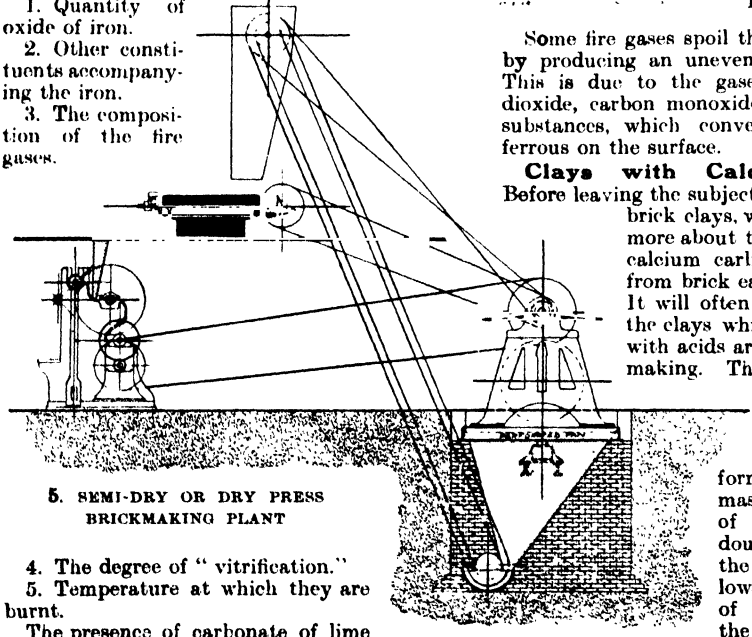
Manganese, a metal allied to iron, also affects the colour of the brick, producing a brown shade, but the proportion of manganese in the clay is so small that it can usually be left out of account.

Modification of Colour. The colour is also much modified by the presence of carbonates of lime and magnesia, and the condition in which the iron itself is present will also affect the colour, so that a knowledge of the percentage of iron in a sample of clay will not indicate accurately what colour the burnt brick will be.

A reference to the course on CHEMISTRY will show that iron, in the chemical sense, may be in either the ferrous, or the ferric state. It is in the latter form that it colours the brick.

The most important factors which affect the colour of a brick have been summed up by the German chemist Seger, who made a life study of clays and their use in making bricks and porcelain. They are

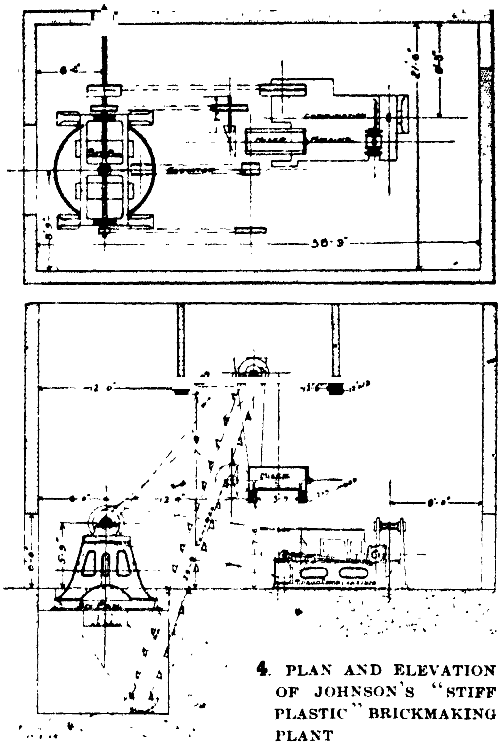
1. Quantity of oxide of iron.
2. Other constituents accompanying the iron.
3. The composition of the fire gases.



5. SEMI-DRY OR DRY PRESS BRICKMAKING PLANT

4. The degree of "vitrification."
5. Temperature at which they are burnt.

The presence of carbonate of lime *bleaches* the colour of bricks, and they burn to a yellow tone, as, for instance, in the case of the well-known London *stocks*. Three per cent. of chalk will neutralise 1 per cent. of iron, and give a yellow instead of a red brick.



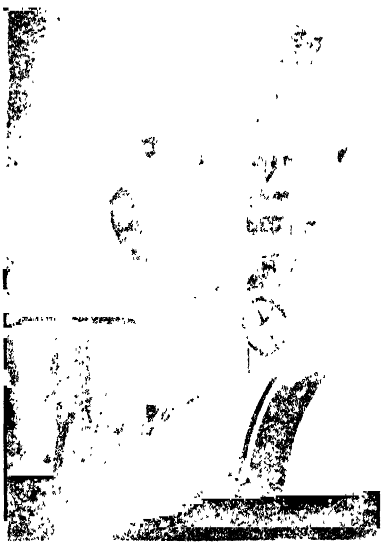
4. PLAN AND ELEVATION OF JOHNSON'S "STIFF PLASTIC" BRICKMAKING PLANT

Some fire gases spoil the colour of the brick, by producing an uneven, mottled appearance. This is due to the gases containing sulphur dioxide, carbon monoxide, and other reducing substances, which convert the ferric iron to ferrous on the surface.

Clays with Calcium Carbonate. Before leaving the subject of the composition of brick clays, we must say something more about the effect produced by calcium carbonate on bricks made from brick earths which contain it. It will often be found stated that the clays which effervesce strongly with acids are unsuitable for brickmaking. This is not always the case ; at all events, if the calcium carbonate is finely divided and distributed uniformly throughout the mass. Lumps, or nodules, of limestone are undoubtedly harmful. As the calcium carbonate lowers the melting point of the clay, it promotes the slight amount of vitrification or fusion necessary in making a sound brick. Twenty-five per cent. of calcium carbonate may be allowed if the brick be well burnt. Such clays can be worked into a bar for hand brickmaking, with 20 to

24 per cent. of water reckoned on the weight of dry substance, whereas the strong clays, free from lime, require 25 to 30 per cent. of water. These points have to be taken into consideration when working the clay in the pug mill. In the process of burning, calcareous clays give off carbon dioxide, which modifies the structure or nature of the brick to a considerable extent, as the escaping gas leaves the brick full of tiny holes, and makes it more porous. In many cases, such a brick will stand the weather much better than a dense, smooth brick. Water which may permeate into the interstices will in cold weather do little harm when it expands on freezing [see PHYSICS], while with a close, hard brick there are still innumerable minute cracks and fissures which absorb water readily, so that when a frost comes the water freezes and rapidly disintegrates the brick.

Hand-made Bricks. This is carried on mostly in the South of England, and is suited to the small deposits of varying composition.



6. SEMI-PLASTIC BRICKMAKING PRESS

Clays are first dug and, if too strong, are mixed with the right proportion of sand or poorer clays by heaping them in layers one on the top of the other. When carted away to be worked up, the men are careful to dig through all the layers, and cart away the different ingredients in the right proportions. If the clay contain flints, chalk, or pieces of rock, it has to be washed. For this purpose, it was formerly the custom to dig a hole 3 ft. deep, termed a *wash back*, or *pan*. The clay was washed out of the mass into this pan, with sufficient water, and left to itself long enough to allow the clay to settle. The water was drained off, and the material dug out. Nowadays modern mills are provided with washing pans having the form of a circular trough. Revolving arms are fixed to a vertical staff in the middle of the trough, and carry harrows suspended by chains. When they are driven round, the harrows churn up the mass of water and clay, which is run off, leaving the deposit of stones, unbroken lumps, etc., on the bottom. The general principle, however, is exactly the same as in the old-fashioned pits. [See also CEMENT.]

Weathering and Tempering. Before the clay is mixed with water, or *tempered*, as it is termed, it is allowed to *weather*, by exposing it to the air. This weathering is of the utmost importance where hand-made bricks are manufactured and where the machinery is not sufficiently powerful to break down lumps of hard rock into which water will not penetrate. Frosty weather is best suited for weathering, owing to the small quantities of water which permeate the crevices, expanding and splitting the stone when frozen. The weathered clay is carted to the pug mill, where it is mixed with the right quantity of water and ground to a uniform pasty mass, or *pugged*.

The old pug mills consisted of pits sunk into the ground in which the clay was stirred up by a revolving arm worked by a sleepy old horse. In a modern pug mill, the motive power is derived from an engine. The mill consists of a large pan in which revolves a vertical shaft, fitted with two horizontal knives. In the bottom of the pan is an opening for letting out the pugged clay, and there is a scraper at the bottom of the shaft for emptying.

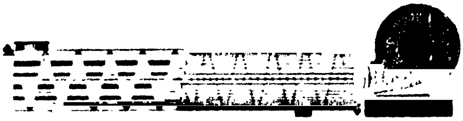
When the clay is sufficiently pugged, it is ready for *moulding*. This used to be done in hand moulds of iron or wood, but modern machines have largely taken the place of such primitive plant [see **11**]. However, owing to the cost of transporting bricks, and the fact that in the South of England small quantities of suitable clay crop up in numerous parts where the installation of expensive machinery would not pay, large quantities of crude, hand-made bricks are still produced.

Wire-cut Bricks. In modern plants the clay is fed between powerful steel rollers, placed directly over the pug mill, which is often arranged horizontally.

The plant in the illustrations [**1**, **2**, and **3**] for working on this system is constructed by Messrs. Wm. Johnson & Sons, of Leeds. On the extreme right-hand side may be seen one of the trolleys in which the clay is brought up from the pit. It runs on rails which slope down to that part of the pit where the clay is being worked. When the trolley is full, it is drawn up by an endless chain, passing round a pulley, seen on the right-hand side of the drawing. The clay is tipped, generally by an automatic arrangement, into the pan, of a type of edge runner, termed a tempering pan. The pan is made to revolve by suitable cogs, and the clay is ground by the heavy rollers seen on the upper floor in **2**, where the plant is shown in transverse section. The clay passes through small holes in the bottom of the pan, and is delivered to the rollers shown on the ground floor, which crush all stones, and the clay passes thence into the pug mill, where it is formed into a column or bar by the expression rollers. The bar is delivered on to a table, on which is a frame provided with a number of vertical steel wires, which can be moved horizontally by means of a lever. By this means the wires are driven through the bar of clay, cutting it up into separate bricks, exactly as in a soap-cutting frame, or when a grocer cuts cheese with a wire. The cutting table is seen diagrammatically on the right-hand side of 3; on the left-hand side are the mixer and crushing rolls.

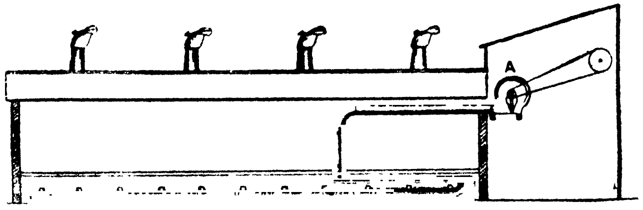
Another System. Another arrangement, due to Messrs. Whittaker & Co., Ltd., for the production of wire-cut bricks is worked on the following system.

The clay is delivered into the grinding mill. This consists of two heavy steel rollers resting on a pan, the bottom of which is made up in sections consisting of steel plates provided with small perforations up to ¼ in. in diameter, and the whole pan revolves, being actuated by the cogwheel above. This plant is similar in construction to Messrs. Johnson's plant as shown in the figures.



7. ROBINSON'S AIR-HEATER AND FAN

The clay is effectively ground, and when small enough passes through the holes into the plate and collects in a pit, from whence it is carried up by the elevator to a screen This consists of a sloping box with a bottom composed of a number of piano wires stretched lengthways. The clay which passes between the wires is conducted into the mixer, while the *tailings*, or larger unreduced lumps, pass over and are returned into the grinding mill. In the mixer the water is added, and the clay worked up to a plastic mass. The mass is delivered into the pug mill, where, after treatment, it is thrust out on to the cutting table, and divided into bricks as already explained. The green bricks by this process have to be dried before they can be put into the kiln. Where possible, this is got over by working the clay semi-dry [5], or by the so-called semi-plastic [4] process.



8. ROBINSON'S HOT-AIR CHAMBER FOR DRYING BRICKS

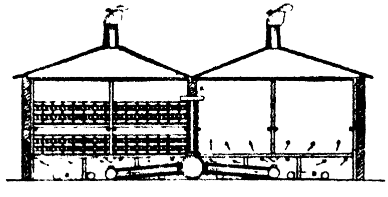
Machine-moulded Bricks. The pits from which the clay is dug are often very extensive — huge excavations in the earth, sometimes 200 ft. deep. The pit slants gently downwards from the machine house, where the bricks are made, and a number of narrow-gauged trolley lines run down to the bottom of the pit or *clay hole*. The *tubs* or small waggons into which the clay is loaded at the bottom of the pit are hauled up by endless chains worked by a pulley connected with the main shafting. When they arrive at the top of the gradient, the clay is tipped out by an automatic arrangement. As fast as the waggons are emptied, they are run down again into the pit to be filled afresh. The workmen dig at the side or bottom of the pit, and occasionally loosen the clay by firing small quantities of gunpowder at the bottom of bore holes.

As the pit is enlarged, care must be taken to remove the earth and soil round the top, so that it does not fall in and contaminate the clay. A good deal of trouble is sometimes experienced by the entrance of water, which must be pumped out when necessary. Indeed, it is almost impossible to continue working during very wet weather.

The clay is first taken to the grinding mill [see 4], a little water being sometimes added to it. The construction of the grinding mill has already been described. The clay is worked so dry that it falls to powder in the hand. As before, it falls through the perforated pan of the grinding mill and is carried up by an elevator, whence it passes through the piano wire screens, and thence to the press. The clay is fed into the mould of the brickmaking machine proper, where it is kept hot by steam. The clay, in a semi-dry condition, is subjected by powerful levers to a pressure of several tons. A brickmaking press is shown in 6.

All sorts of waste materials can be used for making bricks, such as stone chippings, clinker, slate refuse, blast furnace slag, or sand, reduced to a suitably fine powder by powerful machinery, and *bonded* with lime or cement.

The compressed brick is automatically delivered to a table. Sometimes as much as 80 tons pressure is put on the brick, and, although the material was quite powdery as fed into the press, it is now compressed into a solid brick [6], which holds together sufficiently to be handled, and can be put direct into the kiln without previous drying; whereas bricks prepared by the plastic process require to be dried before they can be put into the kiln.

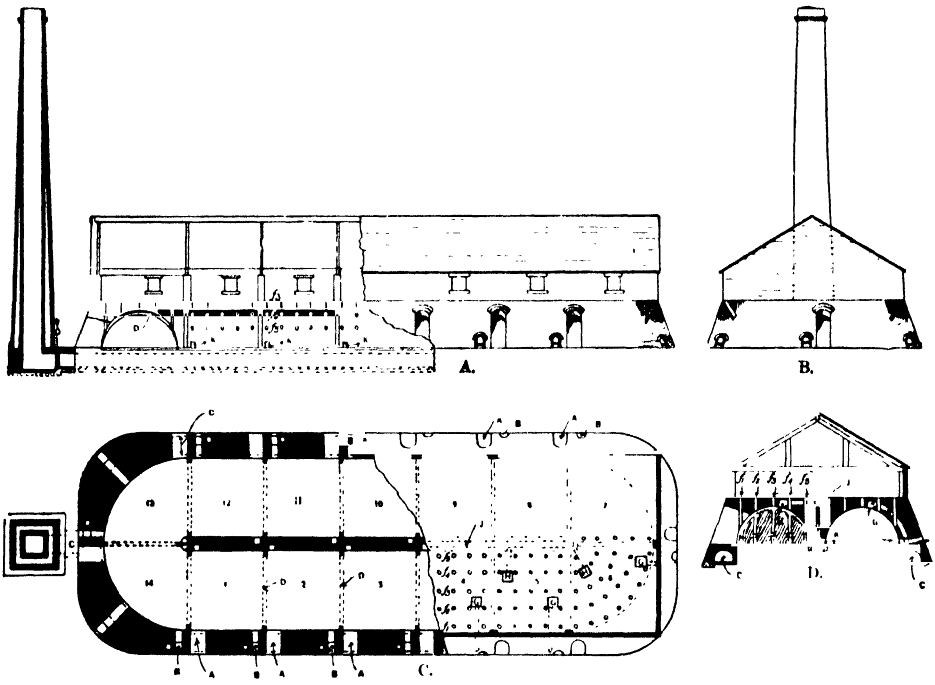


9. DOUBLE-CHAMBER SYSTEM OF BRICK DRYING

Brick Drying. This drying process used always to be carried out in the air, the bricks being piled upon each other in rows, in such a way as to be exposed to the air as much as possible, and covered with a screen or roof to keep off the direct heat of the sun. If fully exposed to the sun they would dry too rapidly, and would almost certainly crack. There is a tendency, however, to replace drying in the open by special drying-rooms, one form of which, constructed by E. Robinson, we may now describe.

In the heater [7], the main feature is the spiral *diaphragm*. Steam is admitted inside the parallel system of tubes, and the wind, driven in by the fan, circulates through them, and travels about four times the outside length of the cylinders. The effect of this is to give a very high efficiency, and a large volume of air can thus be heated to 250° F., or higher, if required. Either live or exhaust steam can be used. If the former, a steam trap is connected, so that only the steam actually condensed is used.

A medium-sized heater of this kind is about 12 feet long by 2 ft. in diameter, and its air inlet and outlet are attached to suit any desired position. Here it is placed under a floor, as illustrated in 8 and 9.



10. OSMAN'S MODIFICATION OF THE HOFFMAN KILN
A. Longitudinal elevation and section. B. End elevation. C. Plan. D. Transverse section

For drying bricks in a long, narrow room, as in 8, a trunk blast-pipe is carried from the heater along the centre, under the floor. This pipe is provided with a series of orifices, so proportioned as to disperse a blast of wind uniformly throughout the whole length of the building. A board of triangular shape is arranged over the discharging orifices, as seen in 9, and the arrows indicate the way in which the blast is dispersed.

Use of Double Chamber. It will be seen that in the arrangement illustrated in 9 a pair of rooms are built side by side, with a heater standing under the partition between them. The fan, not shown here, would be fixed at A [8]. It is represented as viewed from one side. From either side of the heater there is a branch pipe which is carried along the centre of each room. Thus the heater has a separate blast connection into both rooms, and by means of a blast gate on each side the current of wind may be entirely shut off from one room and the whole of it turned into the other room. This construction has the advantage that one heater and fan serves for two rooms, one of which can be cooled down, cleared and refilled, whilst the drying process is going on in the other room.

In one of the rooms [9], a double tier of bricks is seen stacked. The upper tier rests upon shelves of open latticed woodwork. These are readily removed and replaced for clearing or stacking. At B are shown steam-pipes for supplementary heating.

This system of drying applies to wire-cut and such bricks as are handled in the way indicated. It will be understood, however, that this apparatus is equally adapted for what is known as the progressive, or *A B C* mode of working, where the bricks are stacked on cars and run into the dryer on rails. In the latter case it is necessary to excavate the ground, putting all heating appliances below, and leaving a level surface for the car track. It is generally necessary to supplement any blast system of brick-drying with some steam-pipes under the floor. These are shown at B in 9. As a rule motive power for driving the fan is only available in the day time, and it is necessary to maintain some heat. The two independent systems are very convenient for utilising exhaust steam, and when this is turned into the pipes, very little live steam in the blast heater will be sufficient to ensure drying as rapidly as most clays will stand without cracking. By running the fan only during the day, and by allowing the room to cool down at night, bricks of the most delicate clay can be rapidly dried without cracking.

The Sturtevant System. Under ordinary circumstances, a good deal of heat must be left in the kiln gases in order to produce sufficient draught in the chimney. This is economised by the Sturtevant system, which draws these hot gases through drying chambers or tunnels in which the bricks are placed. The induced draught is produced by means of a fan. So constructed, there is no need to build a chimney stack, as the fan creates the necessary draught and has the advantage of being easily regulated. The method is arranged to suit the type of brick. If the latter are very soft they will dry on the floor of the chambers, but it is usually preferable to place them on the shelves of trucks which are run into the tunnels, the hot air passing through lengthways. Some bricks require drying very slowly, while with others the drying may be forced.

11. HAND-BRICK MACHINE

Brick Burning. The old method of burning bricks in stacks in the open without any proper kiln, is still largely practised, especially where, in order to meet local requirements, building operations are proceeding on the spot, and the clay deposit is only a small one. The green or unburnt bricks will usually be those made by hand. They are built up into a stack, or pile, with layers of fine coal between layers of bricks. A hole is left near the bottom for firing, and spaces are left to form air-holes and produce the necessary draught. As many as 50,000 bricks can be burnt in one operation. The heaps should be protected from prevalent winds by luting the crevices with clay or placing hurdles thatched with straw against the sides.

The burning takes several days, and the hot gases and flames find their way through the crevices and air-holes, eventually escaping at the top of the heap. As might be expected in such a primitive arrangement, many of the bricks are very unevenly burnt. The temperature on the inside is much higher than necessary, and there bricks are sometimes over-burnt; while on the outside they are not sufficiently heated and are under-burnt.

Burning in kilns is an improvement upon this method. The first kilns were of simple construction, and intermittent in their action—that is to say, when the bricks were burnt the kiln was allowed to cool down, the burnt bricks drawn and replaced by fresh green bricks. As the kiln could not be entered until it had cooled down, most of the heat given off by the cooling bricks was lost.

Modern kilns are built on the continuous principle—that is to say, the heat given off during burning and cooling serves to drive out moisture and give the preliminary heating to the green bricks. The original continuous kiln was invented by Hoffmann, and the first kiln in this country is said to have been erected at Roundwood Brick Works, near Wakefield, where it is still in use. A modern form of this kiln, as modified by Osman, is shown in the diagram [10].

The Modern Kiln. In principle it consists of an oval framework, roofed in and divided by a centre partition, forming a continuous tunnel, separated into chambers, usually seven or eight on each side, in which the bricks are burnt. The fire travels continuously round these tunnels, and when the heat is at a maximum in, say, chamber 2, the opposite chamber, 9, will be cold. The heat produced in chamber 2, passing on through chambers 3 and 4, etc., heats these in turn; and when the fire has travelled round sufficiently far, chamber 2 will have cooled sufficiently for the burnt bricks to be taken out and replaced by green ones.

The draught is produced by the chimney, but the escaping gases have given up most of their heat in drying and burning the bricks, so that they have cooled to a temperature of 150 to 200° F. before they reach the chimney. The great economy effected will be evident, as none of the heat is lost, and only enough left in the escaping gases to produce the necessary draught.

The fuel is fed into the kiln through small holes, termed *feeding holes*, situated in the arched roof. These are seen at f_1 to f_5 [10], C and D.

The fine coal, or slack, used drops down spaces or pockets left in the bricks as stacked in the chamber underneath. Care is also taken to pile the bricks with spaces between them, so as to allow for the necessary draught; and they are usually arranged in *blades*, or loosely built walls, about 1 in. apart, with spaces about 2 in. wide, termed *traces*, running longitudinally, to take the draught through the bricks.

The Osman Kiln. The Osman kiln shown [10] consists of fourteen chambers. Each chamber has a doorway (A), termed a wicket, through which the bricks are taken when setting or drawing. Each chamber is also provided with what is termed a damper-opening (B), which conveys the draught through the chamber to the main flue (C), running round the kiln under the outside wall, and connected with the chimney. The walls separating the chambers are often temporary, and contain holes corresponding to the traces. As the heat of the chambers is drawn forward it passes through these openings into the next chamber.

Supposing that fire is burning, say, in chamber 1, chambers 2, 3, 4, and 5 may be filled with the green bricks. The dampers corresponding to these chambers will be closed, while 5 will be open, so that the hot gases from 1, passing through 2, 3, 4, and 5, reach the chimney through the flue (C). To prevent cold air in 6 chamber rushing back and checking the draught at 5 damper, the trace-hole openings in the drop wall of 6 are blocked up by pasting paper over them. This paper will gradually burn away when the heat is sufficiently far advanced. When this happens, the damper of 5 is closed and that of 6 opened. The holes in the wall between 6 and 7 are pasted up as before. In this way the heat gradually advances through the chambers; those in front being continuously filled up with fresh green bricks, while those behind are emptied of burnt bricks as soon as they are cool enough. There is an outlet (G) from each chamber, so that the steam gradually driven off from the green bricks is taken from the chamber at the top and drawn into the main flue and away to the chimney. This steam, if allowed to pass through the chambers ahead, would condense on the green bricks, causing them to soften and crush, and would also affect the colour of the brick. It is necessary to draw off this moisture slowly and gently, so as not to crack the green bricks; and to effect this the waste heat through the cooling chambers is drawn upwards through the outlet H, and along a branch flue which joins the central hot air flue at J. The heated air is thence carried down into the chambers at K, containing green bricks, in advance of those actually burnt. The moisture driven off leaves at the point G, reaching the main flue C. When the bricks are taken out they are ready for use.

Fire-clays and Fire-bricks. Such bricks fuse at a very high temperature, and are prepared from special heat-resisting clays. They will stand temperatures at which ordinary bricks would melt and flow like water. Many natural clays are found suitable for their manufacture. They usually consist of silica and alumina, but contain very little iron, lime, or alkalies, as the presence of all these substances tends to lower the melting point of the brick.

Many natural fire-clays are worked for making this class of brick. Such clays are obtained from Dowlais, Stourbridge, and other places.

Dinas bricks, made from dinas clay found in Wales, consist almost entirely of silica, and artificial bricks have been prepared on the same lines by mixing silica with about 1 per cent. of lime. *Ganister,* a fire-brick of a highly refractory nature, is used for lining furnaces.

Much of the fire-clay used in this country comes from Stourbridge, but excellent material is also obtained from Northumberland, Lancashire, Warwickshire, and South Wales.

Many fire-clays are found underlying coal seams, and are hence frequently termed *under clay.* They are usually of dark greenish-grey colour, and of dense consistency. They are generally mined in the same manner as coal. When brought to the surface, the clay is spread in even layers, and allowed to remain several months, that it may become thoroughly "weathered," after which it is taken to a wash mill and worked until the mass attains a regular consistency. It is run out into settling backs, and when the water has evaporated, the mass is cut up and moulded.

To give an idea of the chemical composition of fire clays, we append the following analysis of Stourbridge clay:

Silica	65·10
Alumina	22·20
Magnesia	18
Lime	·14
Oxide of iron	1·92
Potash	·18
Phosphoric acid	·06
Water	9·28
Organic matter	·58
	99·64

Good fire-bricks may be made from the refuse of china clay and quartz sand. Such bricks will consist almost entirely of silica and alumina, with not much more than 2 per cent. of other ingredients.

How to Measure Temperature of the Kiln. It is often of considerable importance, and of great practical interest, to measure the temperatures of the brick kiln, so as to secure even and regular firing—a great desideratum in practical working. The temperature of the kiln is so high that it is not possible to measure it by ordinary thermometers, and there are a number of special devices which are employed for this purpose. Among these, some of the most sensitive and accurate are constructed to work electrically. Many of them depend on the resistance a wire offers to electric current, as the higher the temperature the greater the resistance; but for brickmaking and allied industries simpler contrivances are often used, as, for instance, the Seger cone, which depends for its action on the expansion of a piece of fire-brick when it gets heated in the kiln.

Another appliance is the Watkin Heat Recorder. It is simply a block of very refractory ware, with five recesses or shallow cavities sunk into its top face, in which are placed small pellets of varying fusibility, and of definite composition and melting points. The actual temperature expressed in degrees on the Centigrade and Fahrenheit scales is given in the tables used with the recorders.

They are provided with a special wrapper, which serves to retain the loose pellets in their places, and which is not removed before firing, as it readily burns away. After firing, it does not matter if the loose pellets drop out, as those pieces which fuse will always remain attached to the recorders, and from these the temperatures are read.

Brickmaking concluded

NEW WORK IN OLD FIELDS

Unworked Corners in Old Fields for the Inventor and Scientist. A New Educational Factor. Modern Photography. The Scientific Farmer

By ERNEST A. BRYANT

WITH this article, one aspect of the present course attains finality. Highly important considerations, to which all that has so far appeared under this heading serves as introduction, remain to be reviewed. Succeeding articles in the same course have for their object the inculcation of methods whereby the student, whether his goal be literature, art, science or industry, may seek and win inspiration, and, having gained that inspiration, turn it to practical account in the pursuit to which he shall devote himself. The moral and intellectual development of a man is, of course, as ardently to be sought as that merely mechanical genius into which a well-schooled savage might develop. The character and career of an Edison are greatly to be commended to the study of youth with ambition. They are an inspiration to the zealous, an example to the able, a reproof to the lethargic. But a man's library must not be all Edison ; he must have his Emerson and his Shakespeare ; he must have thought not less than thews, morals as well as muscles. Thomas Brassey could never have provided half the world with railways had he been simply a skilled contractor and engineer.

Character an Asset. Character was as considerable an asset in his gigantic success as the ability of a born engineer. It was his fine moral fibre as much as anything which made his fame in industry world-wide. Almost for the first time it was insisted, in all he did, that work should be honest ; that every engagement entered into should be carried out with the nicest observance of moral as well as legal obligation. Every day, for many years, 75,000 men, far scattered over the world, worked upon his enterprises. Every man of those 75,000 knew that while he could rely upon his master as upon the unfailing rotation of the seasons, each in his individual capacity, no matter how responsible, no matter how insignificant, knew that he was expected to render an honest account for each day's labour. Character, equally with capital and energy and genius, built the railways upon which the fame of this noble Englishman was reared. The earnest student will read and value the articles which follow on this aspect of self-development—the development of character and of mental energy.

There still remain some schemes yet to be mentioned. No pretence is made even to have approximately exhausted the subject. No man's brain could do more than evolve suggestions sufficient to more than touch the fringe of the subject. Probably every reader of the course will be able to suggest a dozen new ideas from each of those contained herein. As has so often been shown, an idea for a specific industry finds acceptance in a totally unexpected quarter. The man who essays the solution of cotton for the making of artificial silk finds a product for the manufacture of incandescent mantles ; while the maker of a new form of metal fencing proves to have the very idea needed for the builder who relies for his walls and floors upon reinforced cement. From a leaf springs the design for the Crystal Palace ; from the boring of a destructive worm the secret for man's sub-aqueous tunnelling ; from the refuse of the coalpit medicine to cure half the ills to which flesh is heir, perfumes to charm the senses, disinfectants to preserve him in health, essences and flavourings to delight his palate. It would be idle to preach to a colliery proprietor or a gas-works owner of the chemical properties of the substance which he handles ; but the story told to the student of chemistry means much to him and mankind, whom he is to benefit.

Cheap Telephones. A business man of standing was asked in what direction he would wish to see progress sought in so simple a matter as office equipment, in time-saving apparatus for a great concern such as that of which he is the head. He did not see any particular in which present-day methods could be improved. Yet that man, if he wished to see the chief men of his dozen departments, would have to send as many separate messages, wasting his own time while each man was making the journey to his counting-house ; wasting, too, the time of each manager as he came from and returned to his own department. The idea of a general installation of cheap telephones throughout his premises did not appeal to him ; verbal messages carried by a junior clerk had always served, and would serve. Yet, in the absence of the responsible head, work may stand still with scores of his employees. The cheap telephone for communication, department with department, and the office with all, is one of the things of the office, the factory, warehouse, shop, and other business establishments of to-morrow.

Economising Time and Money. In America they have, in all the large hotels, an elaborate system of inter-departmental telephony. If a guest wishes to have his bath prepared, he puts the indicator to the number on a dial and presses a button ; if he wishes a meal brought to his room, or one to be prepared for him elsewhere ; to send a telegram, or book a seat at a theatre or concert ; if he wants a paper or a carriage—no matter what, there is the want indicated on the dial. He applies the indicator to it, presses the button and the rest is done for him. This means a great saving of time to the guest. It is not designed, however, wholly for the convenience of the latter. The wages of domestic servants in the United States are high; it is cheaper, hotel proprietors find, to bear the initial outlay necessary for the installation of this instrument than to employ an unlimited number of messengers to run about from floor to floor and from room to room. This instrument, or something of its character, ought to be in the office of every man who has upon his premises a large number of employees, and needs frequently to be in touch with those responsible for the conduct of the several departments. Time saved is money gained.

The Gleaner's Harvest. The man who will take the trouble to re-explore fields in which he is no longer a pioneer will find a rich harvest for the gleaning. Lord Rayleigh stands in the very foreground of the world's scientists. What has he done? The work which places him, with Lord Kelvin and Sir George Stokes, in the ranks of the greatest physicists of the age, has been well summarised in a couple of sentences: "A great part of his theoretical work consists in re-surveying things supposed to be already known, and elaborating their theory into precision and completeness. In this way he has gone over a great portion of the field of physics, and in many cases has either said the last word for the time being, or else started new and fruitful developments." If our giants can stoop to laborious, painstaking work, which to many a young student would seem humdrum, the youthful worker with ambition and new ideas need not be ashamed to seek the golden grain where men before them have applied the sickle.

Not only may we seek improvements of inventions already before the world. There is profitable return in seeking new applications of those inventions. The cinematograph and kindred mechanisms have been, until quite recently, the toy of the promoter of entertainments. Their use in preserving for posterity historic spectacles of our own day has, of course, been recognised, but their value to science and ordinary education has been overlooked.

A New Educational Factor. Now, however, it is found that the cinematograph may be a most valuable adjunct to the lecture, illustrating scientific processes, surgical operations, and what not. The idea is capable of development in many ways. But there is a considerable barrier in the way of its immediate popular application—the cost is excessive. The films for the negatives now cost, it is found, at the rate of a sovereign for every minute of exposure. That makes the common use of the cinematograph prohibitive. A newer, cheaper substance is sought. When that comes, every school, every lecture-hall, may have its studies of special subjects illustrated by this wonderful handmaid of science. The eye is a wonderful aid to assimilation of knowledge.

A child will learn by ear to utter a sequence of sounds to represent certain ideas, and will repeat such sounds with some pretence at accuracy. If that child be asked to write out what it has learnt the result will be ludicrous. We spell by the eye. In any average company of a dozen persons not six will be able to spell verbally any ordinary word which has a curious spelling. But they will write that word correctly. In doubt as to a spelling, a man instinctively takes up pencil and paper and writes it. If the letters are not set down in conventional order, the eye, that diligent servant, at once detects the mistake, though the ear cannot. The cinematograph would be an invaluable aid to the eye and make instruction more easy and more attractive. But its general application to such methods is commercially impossible until we get cheaper films. The old ground must be gone over again, but more thoroughly.

Doubling the Microscope's Use. Another excellent example of the result of re-exploration comes to hand in a new addition to the functions of the microscope. All these years we have had to be content with having one field of observation at a time. If two objects were to be compared, they must be examined separately. It was infinitely laborious and tedious, and comparison could not be as exact as the careful man would wish. But diligent seekers have been toiling away in the old paths, and seem about to win their reward. A new attachment is being tried which will give the microscopist two fields of observation at once. The old stereoscope used to give us two pictures to form one under the influence of the lens. This new apparatus reverses the process, and enables the two eyes simultaneously to have two fields under microscopic observation. For comparative work this will, of course, be invaluable, and the time saved to the microscopist devoted to work of this character will be practically doubled.

The story of sulphuric acid is another illuminating example. Two processes, both very old, have been in use with but scanty modifications, as well on the Continent as in England. The English method has involved the erection of vast chambers of lead, bound together with a mighty framework of timber, and elevated upon arches of masonry each several feet above the ground. This process has been unwieldy; it has consumed space unnecessarily, and it frequently only succeeded in yielding an acid highly charged with impurities. The circumstances have constituted an insistent call upon the attention of the inventive.

The Call of Necessity. When Queen Victoria came to the throne we looked entirely to Sicily for the supply of sulphur, out of which to manufacture our sulphuric acid. A year after that event, however, the Sicilian Government established a monopoly of the sulphur trade. The result was an immediate and heavy advance in price. Human ingenuity, when put to the test, can generally get round, or over, a wall which it cannot go through; it did in this case. Sicilian sulphur failing, chemists cast about for a new substance, and iron pyrites proved the thing required. Ever since then iron pyrites has encroached upon the preserve of sulphur, and to-day is infinitely more in requisition than the original substance. But there has always been the objection that in it are foreign substances, the most deleterious being arsenical compounds, which render it inapplicable for many purposes.

At last two persevering students in a chemical laboratory have solved the problem. The huge and clumsy chamber is to disappear. A new process has been evolved. By forcing different gases through a tube containing platinum-asbestos, the acid is formed by what the chemist knows as catalytic action. Catalysis is a term in physics full of mystery and fascination, which the student will study in other courses of the SELF-EDUCATOR. Here it operates in a very small apparatus, produces a pure acid, is already commercially worked, and, at a step, foreshadows a complete revolution in the industry. For it is an industry to itself, this making of sulphuric acid. Great quantities are required for the manufacture of soda, for bleaching, for calico-printing and dyeing. The manufacturer finds it indispensable; the chemist requires it for the laboratory; the medical practitioner could not make up his medicines without it. So universal is its use that men have been content to regard the last word as said in its method of production.

The New Photography. The system already described comes under the heading of contact process. A more popular application of the contact process relates to photography. By the new method the photographer runs over his negative a solution of ether containing hydrogen peroxide. Here, again, catalysis operates in its bewilderingly arbitrary way, but all for good. Wherever the silver on the negative is reduced, the hydrogen peroxide is immediately destroyed, but where the silver is not reduced, the hydrogen peroxide is not destroyed. The consequence is that when a negative so treated is brought in contact with sensitised paper it produces practically the same change in that paper which would have resulted from the exposure of the latter to the sun. The sun is no longer necessary for printing-out! To how many thousands of amateur photographers, permitted daily only fragmentary leisure, may this prove a boon. Not only does it save their time; it will tend vastly to save their pockets, for, instead of the costly sensitised papers now employed, a much less expensive one will be possible.

Such is some of the gold from old mines. The latter are far from exhausted. Note the advance in steam-raising which has occurred within the days of men not yet in their prime. A score of years ago the normal pressure for a boiler was about 50 lb. to the square inch. Men have worked steadily at improvements, and to-day the modern installation has 180 lb. pressure to the square inch. Again, twenty years ago, ordinary wet steam was employed, steam just as it came from the boiler. To-day the steam has to be superheated through a temperature of 180 degrees Fahrenheit. At first it was tried as gas, but to-day this superheated steam with the pressure indicated is the steam by which our engines are driven. Yet twenty years ago the engineers thought perfection was expressed in the apparatus then at their disposal.

The Scientific Farmer. There is another field which has not yet been exhaustively exploited—the field over which the dairy farmer is lord. As it has been already pointed out, new methods are sought for the distribution of pure milk in centres of population. We have to deal not with effect but cause; not to lament the sale of milk injurious to health, but to secure that milk shall not become unhealthy in condition before sale. Very rightly the hand of the law descends upon the man who has recourse to "preservatives" so-called. Pasteur gave his time in vain to the study of this question if at this day "Pasteurising" of milk has been forgotten or ignored. By this method milk can be safely kept long enough for its distribution in a sweet and sound condition. Its use is slowly being adopted in England. But the English farmer leaves with reluctance the rut in which his forbears trod. He grumbles at the sale of foreign butter, but refuses to recognise, or at any rate to alter, the fact that his "fresh" butter will not keep. With every desire to encourage the sale of the home-made butter, than which at its best none in the world is better, we all know that the English product is apt all too soon to go rancid. The reason, apparently, is that the maker either does not take the trouble, or has not the means necessary, to eliminate the buttermilk whose "turning" spoils the whole supply of butter. Yet it can be done in this country. The dairy farmer will have to recognise the importance of co-operating so that he can have, in a central part of the area to which he belongs, a "creamery" to which he and his neighbours can send their milk; and there, with the best of plant, have their butter and cheese made, and the good name of the English material re-established.

TRACING AND CUTTING OUT BOYS' SUITS

Continued from p 1113

Drafting Sleeves, Vest and Knickers. Tracing the Pattern. How to Place the Pattern on the Cloth. Cutting Out

By Mrs. W. H. SMITH and AZÊLINE LEWIS

The Sleeve. For this a piece of paper 19 in. by 9 in. is needed; 2 in. down from top and 1 in. in from edge, draw two parallel lines, half the breast measure apart (6½ in.). Letter the corners A and B. C is midway between A and B: C to D, 1 in.; A to E, same distance as J^a to C^a, in Back Draft [**16**, page 1112].

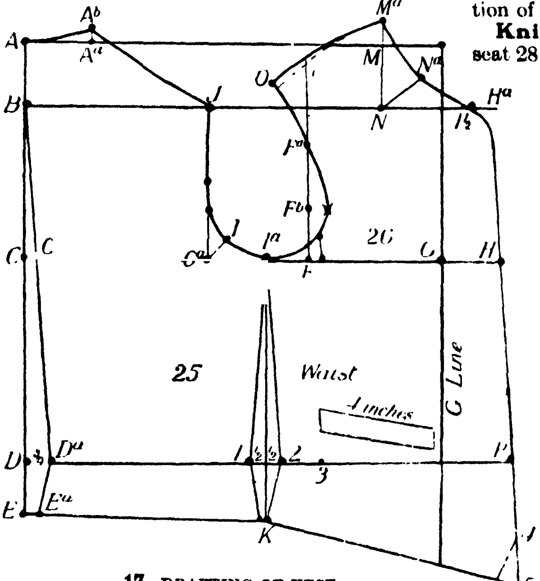
E to F is one-fourth; F to G the same; F to H, ¾ in.; B to I, 1 in.; A to J, length of sleeve, omitting width of back [see broken line, **15**].

Square a line out from J, J to K, 1 in.; K to L, one-third of breast, plus ½ in. M is midway between K and E; square elbow line out from M; M to N, ¾ in. Curve top of sleeve from E, through G and D to B, and from E through H to I. Slightly curve from I to within 2½ in. to elbow line. Curve from E through N to K.

Pockets. 2 in. out and down from 3 draw a line 4½ in. for pocket opening; for position, see diagram. The flap is 1½ in. deep [**15**].

Vest. Working scale half breast (13 in.), half waist (13 in.); ¼ in. turnings are allowed on all seams, but if the cloth is very thick allow ¼ in. extra on fronts.

Drafting the Vest. This method of drafting vests will be found most useful, it being so arranged that it will fit either the smallest or the largest sizes that would be called for [**17**].



17. DRAFTING OF VEST

Begin the drafting as for coat.

A to E, 14 in.; D to E, 1½ in., or length required; D to D^a, ¾ in. Curve from ¼ in. in from E, through D^a to B. Back line to C^a, one-third of breast, plus 1½ in. (5¾ in.), to F, two-thirds (8¾ in.), on to G, half breast; to H, 2 in. more than the measure. G line to H^a, 1½ in.; C^a to I, one-twelfth. I^a is midway between back line and H.

Draw line from I^a, 2 in. below waist line, and make K; 1 and 2 are ½ in. to right and left of line K. Draw lines from K through I. to I^a, also through 2 to same point, and from K to E. Curve from I^a through I to J line. Make a dot ½ in. to right of F, square down to waist line and make 3; 3 to P, half waist (6½ in.), draw line from H through P to bottom of paper; curve from H to within ½ in. of H^a (or lower if desired); continue neck, shoulder, and armhole curves as in **15**.

P to 4, 2 in.; P to 5, 3½ in. Draw line from 5 to K; 5 to 6, ¾ in.; draw line from 6 to 4. K line divides the vest.

The ordinary length of slit, or opening at side, is 2 in.; this should be left in all vests to allow of the expansion of 2 in. which takes place when sitting For position of pocket, see diagram.

Knickers. Waist 26 in., seat 28 in., side length 18 in, inside leg 10 in. Working scale half waist and half seat; ¼ in. turnings are allowed on all seams. First draw a line 2 in. in from edge of paper. 1 to 2, side length (18 in.); 2 to A, inside leg (10 in.). This will leave 8 in. for the rise of body. Square line from A about 10½ in.; A to B, half seat (7 in.); A to C, two-thirds (9½ in.); C to D one-twelfth. B to B^a one-twelfth.

Square line from B, raising the ruler ½ in. above A; if this is omitted the knickers will be too tight in front waist. B to 3, half-seat, plus 1 in.; 3 to 4, 2 in. Draw lines from 3 and 4 to side line; B to E, one-third of seat and 1 in. (5¾ in.); A to F. quarter of seat (3½ in.); E to F^a half seat and 1½ in. [**18**].

The Seat Angle. Draw line from C through E, make G 3 in. up from line 4; spring out ¼ in. and connect to back line; 3 to H, half waist; from back line to I, half waist and 1 in.; back line to J, half waist and ½ in.; 4 to K the same. Draw line across top of seat angle 1½ in. out and down from G.

The Leg. 2 to L, 1 in.; L to M 6½ in., or width round the knee required; draw line from M to C, gradually curve from M to D.

Draw line from L through F^4 and slightly curve through I to J; draw line from J to G; and curve from K through H to A, curving slightly to the right of F. Gradually curve from E through B^a to C, and from E to D.

TRACING THE PATTERN

Either a stiletto or a single tracing-wheel and a stiff sheet of paper are required. Lay the drafting on the paper, and place something heavy on it to prevent its moving.

Front. Trace from 1 through 3 to I^a round the armhole, shoulder, neck curve, front and bottom. Mark pocket openings and inset mark for sleeve ¾ in. up from bust-line on armhole curve. Remove the drafting and cut out the part traced [**15**].

Back. Trace from K through 2 to I and J; from J to A^b; A^b to A, and A to E^a, and along bottom E^a to K. Remove the drafting and cut out. I and I^a must be placed together when making.

Sleeve. Upper part. Trace from K through N, E, G, D, B, and thence down to L, and along to K. Cut out.

Under part. From K through N, E, H, I, O, and L to K, and cut out [**16**].

Vest. Front. This can be simply cut from K through 2 to I^a, and round the armhole, shoulder, neck, and front from 4 to 6 and on to K [**17**].

Back. From K through 1 to I^a, thence to I round armhole, shoulder, and neck, and from A to D^a, and E^a to K.

Knickers. Front. Trace the bottom first from L through M on to C through B^a to 4; from 4 to K, H, and outside F to L [**18**].

Be sure to trace from H to 3 and A to C. Remove the draft, and cut out.

Back. Replace the draft on another piece of paper, trace bottom from L to M, on to D through E to G; then to J through F^a to L. Mark the seat-line from outside A to D and also I and J, as the latter join to K and H in making.

This system of obtaining the pattern from the draft is simplified for beginners; we are not dealing with those who have learned *Tailoring* and *Cutting*. We shall, however, advance as we draft, and make larger garments.

When cutting out the back, remember to add on the triangular piece which has been taken off in the front draft—*i.e.*, from 1 to K.

Placing Pattern on the Cloth. The material should be laid on the table with the fold towards the worker. Press out all creases before laying on the pattern. In every instance the cloth should be tried to ascertain if there is a pile. Place the pattern so that the pile runs from right to left. 1¾ to 2 yd. of 50 or 54 in. cloth will be required [**19**].

The necessary linings and trimmings for boy's suit are as follows:

For Coat and Vest: ⅝ yd. of Italian, or 1¼ yd. of Sateen, 1 yd. Silesia for sleeves and inside lining of vest, ¼ yd. black Silesia for pockets, ¼ yd. black linen, ¾ yd. of canvas, ½ doz. coat and ½ doz. vest buttons to match, a small reel of machine silk for the edges of fronts and cuffs, ¾ yd. of twist, No. 8, and two reels of cotton, Nos. 30 and 36.

For Knickers: Twice their length will be required, and ½ yd. of strong Silesia or pocketing. For the machine, a reel of Knox's fine machine thread, or No. 16 to 24 cotton for the bobbin or shuttle, and No. 30 for the top, ½ doz. large and ½ doz. small buttons, and a packet of tailor's needles, No. 4 to 8.

The pattern should now be outlined with chalk.

Coat. Mark I and I^a, the waist-line on back and front [2 and 3 in **15**], and the pocket-openings. The back is generally placed to the fold. Now mark all round the pattern, leaving an inlay of ¾ of an inch on the shoulder, and just a little from N^a to M^a, also an inlay on the front side seam. Mark the inset for sleeve ¾ in. up from bust-line on armhole curve. The facings must be joined, and should go into the shoulder; they are about 3 in. wide at the bottom. About 1 in. should be left on bottom of coat [**19**] for turn-up or inlay.

Sleeve. It is advisable to leave an inlay of ½ in. on the back seams, and on the bottoms quite 2½ in.

Vest. The fronts only are cut in cloth. Chalk all round the front, also the pocket-opening. The facings should be 1½ in. wide, and taken from seam to shoulder [**19**].

The back is generally made of good black Silesia, and the lining of a light one.

Knickers. In chalking, the pocket facings can be left on, from H to F, and F^a to I, about 1 in. This will save trouble in making.

A good inlay must be left on the back, as from G to D [**18**]. The seat and waist-lines, as from 3 to H, must be marked. It is advisable to leave inlays, or turnings, on the side and inside seams, and from 1½ to 2 in. at the bottom, if cloth permits.

The suit is now ready to cut out and thread-mark.

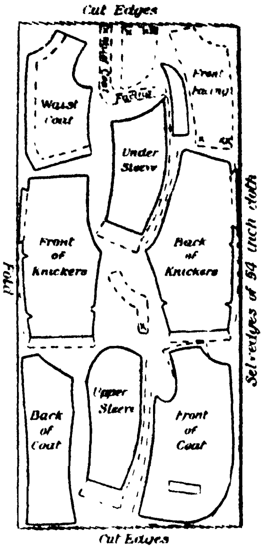
Thread-marking. This is the first operation after the parts are cut out. Beginners should remember that there are two pieces of cloth, and that only one is chalk-marked, the other being outlined by the process about to be described.

Take a No. 5 or 6 needle threaded with double tacking cotton, without knot [see **4**, p. 1111]. Take care to have the stitches as small as possible, and ½ in. apart, round the neck and armhole curves. Having cut the loops between the stitches, cut the threads between the cloth, raising the top piece very carefully, and allowing only sufficient room for the scissors to snip the cotton that holds them together, so that the stitches are not pulled out. When this is finished, each piece will hold the thread-marks, and so indicate the outline of the pattern.

The seams are taken ¼ in. inside the thread-marks, or inturns, the uses of which are evident when any alteration has to be made. Be sure to thread-mark the pockets, also position of buttons and holes.

Back. This must be thread-marked in the same way as the front. It is advisable for beginners to practise thread-marking on two pieces of cloth, as it is an absolute necessity for good tailoring. The sleeves, vest, and knickers are thread-marked on all chalk-marks.

The Pockets. When the various portions are thread-marked, the first process is that of making the pockets. Two pieces of cloth and two of lining are required for the flaps. Cut them ¼ in. longer, and ¾ in. wider, than marked in **15**, then prepare in the following manner.



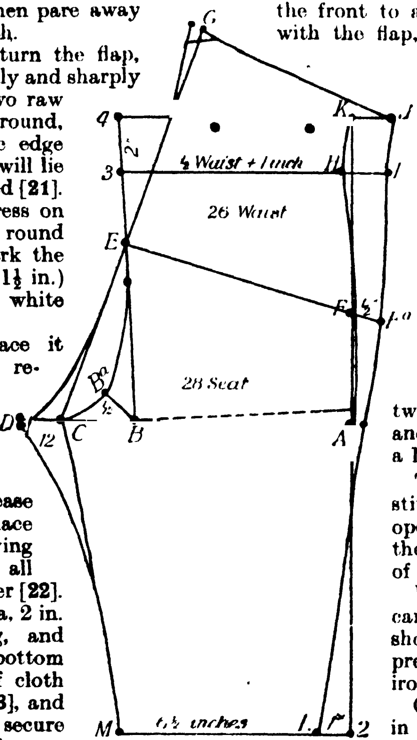
19. ARRANGING PATTERN ON MATERIAL

Baste each piece of cloth on its corresponding lining through the centre to within ⅛ in. of each end [**20**]. Tack round the edge, beginning at the top right-hand corner, keeping the cloth ⅛ in. in from lining, and fulling the cloth on at the corners about 1 in. on either side. This allows it to set flat on the right side, which it would not do if the lining were loose, when the flaps would curl up instead of under. Machine round the edge quite close to the tacking, then pare away the lining even with the cloth.

Take out the tackings; turn the flap, working the corners out evenly and sharply with a bodkin; tack the two raw edges together and baste round, working the cloth over the edge all round, so that the seam will lie ⅛ in. underneath when finished [**21**].

Place a cloth over and press on the wrong side, then machine round 1/16 in. from the edge. Mark the depth of flap (in this case 1½ in.) with a piece of chalk or white cotton.

Take the left front, place it right side uppermost, and re-mark the pocket-opening exactly the same length as flap; turn over, take a strip of strong linen, 2 in. wide and 2 in. longer than the opening, make a crease through the centre, and place this on the thread-marks, leaving 1 in. at either end; baste all round and turn the front over [**22**]. Take a piece of strong Silesia, 2 in. wider than pocket-opening, and long enough to escape the bottom by 1 in.; baste a strip of cloth 1 in. wide along the top [**23**], and stitch along the lower edge to secure the raw edge of cloth to pocket.



18. DRAFTING OF KNICKERS

Now place the top edge (cloth facing underneath) close to the thread-marks of opening, and baste to coat front ¼ in. below the latter [**24**]. Next put the flap on the front, lining uppermost, with the chalk line ⅛ in. above the thread-marks; baste in position, and stitch on chalk-line and along the lower part of opening ⅛ in. from thread-marks [**24**].

Cut along the thread-marks to within ¼ in. of opening, and snip the corners at both ends about ¼ in. on either side to form a V [**25**].

Nick the Silesia at either end to allow the pocket to turn over properly, remove the tackings round the opening, and turn the pocket inside out through the opening; tack along the top, working the two edges evenly together with the finger and thumb, also tacking the two V's back at either end. Stitch from corner to corner only, as from *a* to *b*, keeping as close to the edge as possible. Turn the flap down, press the edges inside through the opening up towards the shoulder, keeping them perfectly level, and baste for stitching [**26**].

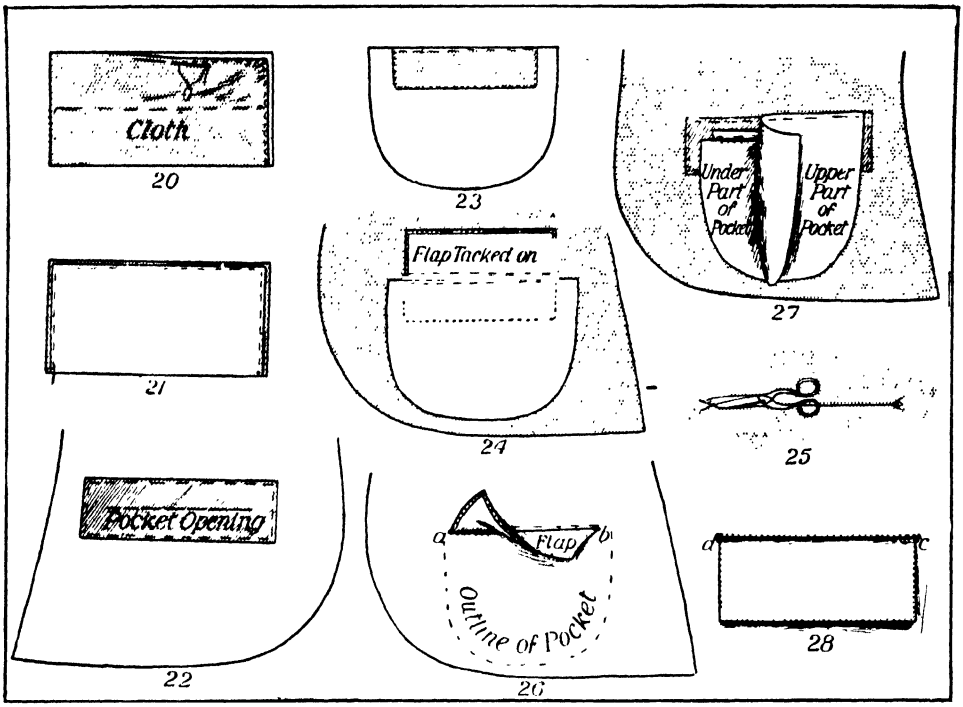
Now take the back of pocket, which must be 1 in. longer than the front to allow of its being stitched in with the flap, turn the fore part of coat wrong side uppermost, and place the Silesia 1 in. above the opening; then baste along the top [**27**].

Turn over on the right side, make the ends neat, pressing the V's back with a needle, stitch along the top of flap as close to the edge as possible, beginning ¼ in. below the flap, and terminating ¼ in. below it at the other side, thus neatening and strengthening the ends. Secure the ends of pocket-mouth with two more rows of stitching, and finish off in the shape of a D, as from *c* to *d* [**28**].

Tack round the pocket, and stitch, beginning ½ in. from opening and stitching through the linen stays at both ends of pocket [**29**, **30**, and **31**].

We are now ready for the canvas, the selvedges of which should be slightly damped and pressed all over with a hot iron—*not ironed.*

Cut the canvas as shown in diagram of right and left fronts [**29** and **30**], the selvedge to the edge of front, and cut edge overlapping pocket 1 in. Place the canvas on the wrong side of fore part of coat, and baste round the edges, keeping



20—28. THE MAKING OF A POCKET

it easy across the chest, over the shoulders, and round the armholes; cut the canvas 1½ in. from the neck and 1½ in. down, and insert a wedge-shaped piece of canvas about ¾ in. wide and 2 in. long [31].

The shoulder near the neck should be stretched.

Slit the canvas two or three times round the armhole, then pare the former away ¼ in. round the front and neck, and, before proceeding any further, roll the corner over the left hand, and tack with five or six long stitches on the right side, which will prevent the canvas from curling outward.

Take a strip of linen cut selvedge-wise, 1 in. wide, which should be pressed with a hot iron, turn in ¼ in.; place the fold a shade beyond the canvas, baste to canvas from the bottom, holding the linen rather tightly for about 3 in. round the corner, as from *a* to *f*, in **30**. Tack the linen on either side to the canvas. It must be remembered that this should be tacked rather tightly at the point at top and round the neck to within 1 in. of shoulder thread-marks.

Press the linen stay, which has just been put on, round the front and also over the pocket. Place the cloth facing on the table with right side uppermost, and neck to the left hand, put the fore part of coat on the top of this, keeping the edge ¼ in. in from that of facing; put one row of basting from bottom to shoulder to hold in position, and baste round the edges, taking care that the facing is eased at the corners from *a* to *f* [**30**]. Stitch the edges ⅛ in. from linen stay. Take out the bastings, open, and press the seam on the narrow side of sleeve-board, cut away the edges to within ⅛ in., turn inside out, work the edges well under, using a bodkin for the corners to make them a nice shape, then baste round the edge on the inside, keeping the seam ⅛ in. in from the edge. This is very important, and there must also be a tacking down the centre and along the raw edge [**29**].

The right front is made in the same way, but, before the facing is put on, an extra stay must be tacked on for the buttons. This should be a strip of canvas 2 in. wide, cut selvedge-wise, and long enough to hold the first and last buttons (in this case 13 in.). Baste to the front ¾ in. from the edge, and ½ in. from the neck—it must be quite loose when basted on to the under part of canvas—then tack all round to the canvas [**31**].

Proceed now as for the left front, then place the two fronts together and see they are exactly the same length; if not, they should be corrected, and any needed alteration made. Mark the spaces for the buttonholes, 4 in. apart, marking the first ½ in. down from the neck, and ⅜ in. in from the edge, in the same way as shown in **15**.

The holes must be worked on the left front, and ¼ in. longer than the diameter of the buttons, to allow these to go through without any pressure [**13, page 1111**]. Place the left front over the right, with the bar of the buttonholes touching the edge of right front, mark through the eyes of the holes with a piece of pipeclay for the buttons, which, however, should be put on last of all.

Linings. We are now ready for the linings. Cut out the fronts, allowing ¼ in. turnings on the front, and the same amount of inlays on the side, as in the fore-parts of the cloth. The back must be cut large enough to allow a pleat, down the centre, of 1 in.—that is, ½ in. under and ½ in. over, to prevent any tightness across the back when finished.

Tack the fore-parts to the back, beginning at the top, placing the parts marked I and I^a together [15]. Keep the thread marks at the bottom even, and baste the seam ¼ in. in from the thread marks. It is advisable at this stage to tack the shoulders together and to try the coat on, and to make any alteration that may be required at the neck and armhole, either by taking in or letting out.

When this has been done satisfactorily the tacking should be removed from the shoulders, which will make it easier for stitching and pressing the seams.

Stitch the side seams, remove the tackings, open, and press; baste the bottom up to the thread marks, and serge [see SERGING, page 1111] to the coat, but the stitches must on no account show through. To avoid this, a No. 7 or 8 tailor's needle and fine silk or cotton must be used, and only a thread of the cloth must be taken up on the needle.

Remove the basting from the bottom, place over a damp cloth (which must be wrung as dry as possible), and press round the bottom and the fronts. It is most important that the cloth should be nearly dry, or the material will become spongy.

Now put a linen stay on the back of each pocket, securing it firmly and tacking to the armhole [29 and 31].

Take the front linings, turn in the front ¼ in., and place ¼ in. over the facing; baste in position, keeping it easy both in length and width, and quite loose round the armhole.

The Back Lining. Place the back lining with the pleat to the centre of back, keeping this also loose in length and width; baste in position, turn in the side seams, tack down, and see that it fits well. Turn up the bottom a little over the edge of the inturn, and baste all round. Tack the shoulders (not the canvas or facing), and stitch; remove the basting, open, and press, stretching the shoulder towards the neck to fit the back.

Lay the canvas flat over the shoulders and secure to the turnings; lay the cloth flat over the canvas and secure it to hold in position.

Continue the linen stay from the left fore-part across the back of the neck, to the right; tack the cloth over the linen stay, serge to the shoulders and back, and press. Now fit the lining over the shoulders and tack, but it should not be felled in till after the sleeves are inserted.

OXYGEN AND OTHER GASES

Commercial Recovery of Oxygen. Oxygen and Life. The Atmosphere. Ozone and the Newly-discovered Gases. The Function of the Sea

By Dr. C. W. SALEEBY

Oxygen and Air. We must now make a systematic study of the most important element. We have mentioned it several times for purposes of illustration. If we were to adhere strictly to our treatment of the elements in groups, we should have to consider oxygen and sulphur together. These two elements have considerable resemblances to one another, and should therefore always be associated in the mind of the student. But oxygen is so supremely important, both as an ingredient of the air and in its relation to life, that it must always dominate our thoughts.

As the reader already knows, it is a gas. It was first discovered by Priestley and Scheele about a century and a quarter ago ; its atomic weight is about 16, and it is thus slightly denser than air, of which it constitutes about one-fifth. It may be prepared in small quantities by Priestley's method of heating the red oxide of mercury, or it may be turned out of water by means of chlorine, or may be obtained from its various compounds by means of electrolysis.

Nowadays, oxygen has attained considerable commercial importance. Since the process of combustion, or combination with oxygen, occurs more rapidly and produces more heat in the presence of pure oxygen than in the presence of air, the element is very frequently used in its pure form in many metallurgical operations It is also largely used in order to produce the brilliant light which is given out by superheated lime and which is called limelight. Its use in this connection has already been explained. Furthermore, pure oxygen is now extensively used in medicine, for there are a large number of diseased conditions in which the inhalation of this gas in its pure form, instead of its ordinary inhalation diluted with nitrogen in the air, is of the utmost value. Hence it has become necessary to acquire some means of obtaining large quantities of oxygen as cheaply as possible.

Brins' Process. The most important of the commercial processes is known as Brins', and is easily explained. The oxide of barium is heated in compressed air to a red heat, and is converted into the peroxide or dioxide, since under these conditions it takes up into itself a certain quantity of the oxygen of the air, the nitrogen of which escapes. Now, when the pressure is reduced, the extra oxygen which has been taken up into the peroxide is liberated again, and can be readily collected. The result of its liberation is to leave behind just the same barium oxide with which the process was started, and so it may go on again and again. Thus, the essential materials for the process are merely air, which has no cost, and barium oxide, which can be used over and over again, and hence the process is exceedingly cheap. The oxygen is stored at a high pressure in a steel cylinder to which a tube can readily be attached, and when a stop-cock is turned, the oxygen rapidly escapes. When the cylinder is being used in the sick-room, the noise made by the escaping oxygen is usually sufficient to indicate that it is escaping, but a simple test can be applied by placing a glowing match-end at the mouth of the tube. If the oxygen is escaping, the rapidity of combustion of the match will be so increased that it will immediately burst into flame.

Oxygen is a colourless, tasteless, odourless gas, forming, as we have seen, eight-ninths of the weight of water, more than one-fifth of the volume of the air, and actually more than one-half the weight of the solid matter that forms the crust of the earth. It is the most widely diffused of all the elements. It has been liquefied and frozen by Sir James Dewar.

Oxygen and Life. By derivation oxygen means the acid-maker, and its function in this respect has already been explained, but it might almost as well be called biogen, to indicate that it is the life-maker. Every living thing, without exception, depends for the processes of its life upon a continuous supply of oxygen. This fact is supremely important and must be carefully studied.

The students of living things tell us that there is a universal function which is common to them all and continuous in them all. This is termed *respiration*. There are no exceptions to this rule, though it was at one time thought that there might be certain exceptions. When the great French chemist Pasteur, the founder of the new science of bacteriology, came to consider the conditions under which bacteria, or microbes, as he called them, grow, he found that they could be divided into two great groups—those that required air for their life, and those that required absence of air for their life. The first he called ærobic, and the second anærobic. At first this looks as if the microbes belonging to the latter group were an exception to our general rule, for it is the presence of free oxygen in the air that arrests their growth ; but it was soon found that unless compounds containing oxygen be present in the materials in which these microbes grow, they immediately die outright. Though they cannot live in air, they cannot, on the other hand, live except in the presence of compounds containing oxygen, which they take from these compounds, thereby, of course, decomposing them. Hence it is true to say that there are no exceptions whatever to the universal rule that oxygen is the life-giving element. There is also the fact that in every kind of living matter, without exception, oxygen is invariably and necessarily found. It is a constant constituent of protoplasm, the "physical basis of life." It is found in proteids and carbohydrates, afterwards to be studied, and though it is not a necessary ingredient of fats, yet it is invariably a constituent of the living part of the curious animal cells in which fat is stored.

Oxidation and Reduction. Now, the process of combining oxygen with any substance is called oxidation, and the process of removing oxygen from any substance that already contains it is known, as we have briefly noted already, as reduction. Changes in these respects occur in a vast majority of all chemical processes, and hence these two words are of the utmost importance and convenience in chemistry. Henceforward we shall use them freely, and assume that the reader is familiar with them. He might expect that the opposite to oxidation would be deoxidation, and that word is sometimes used; but the much more frequent use of the word reduction gives some indication of the importance of this element.

Chemistry of Respiration. Now, let us look a little further into the question of the oxidation of living matter, which is the object of respiration. The products of this oxidation are extremely simple, and consist almost entirely of carbon dioxide (CO_2), and water (H_2O). But biological chemistry has discovered an extremely important fact regarding this process of oxidation. If we consider an ordinary speck of dead oxidisable material exposed to the action of the air, we find, as we might well expect, that it is its outside or its surface which first shows signs of oxidation; the central part of the material can only be oxidised when all the outside is crumbled away in the form of oxide. But the case is profoundly different when we come to consider a particle of living matter similarly exposed to the air. Its respiration by no means consists of a mere oxidation of its surface. What happens is that, in some way which we are yet far from understanding, the oxygen is taken up into the very substance of the living matter and then disposed of. But the reader must not imagine that the means by which human beings breathe is an illustration of this fact; we are referring not to that obvious breathing, but to the real breathing which occurs when the oxygen is brought into contact with the living matter. What we are attempting to describe is true of every living cell, no matter whether it be a cell of one of your muscles to which your blood is now conveying some oxygen just derived from the lungs, or whether it be such another living cell as one of the tiny microbes that exist everywhere. The point is that the living cell, whether it be an independent organism or merely a humble part of a complex organism such as man, is not at all oxidised by the mere action of oxygen upon its surface, but first of all takes up the oxygen into itself, and distributes it in the most complete and intimate way. This is the fact which we attempt to express when we say that the respiration or oxidation of living things is *intra-cellular*—that is to say, *within the cells*. But we may go further; the facts show that before the process of oxidation actually occurs, the oxygen is actually taken up by the very molecules of the living substance, which, indeed, have the most extraordinary power of retaining it when necessary, until there may be need for the production of the energy which results from oxidation. Hence, we must learn the remarkable fact which is described as the *intra-molecular respiration of living protoplasm*. When the living thing dies, the dead protoplasm, if exposed to air, continues to undergo oxidation. But that is of a very different kind. It is now merely the same oxidation, proceeding according to the ordinary physical laws of inorganic nature, that is seen when the surface of any ordinary metal becomes dulled by superficial oxidation.

Oxidation and Growth. We must not be misinterpreted as stating that the laws of physics and chemistry are not applicable in the world of life: we are merely insisting that there is a profound difference, which we are as yet very far from understanding, between the processes of oxidation that may be observed anywhere, and those infinitely more subtle processes of oxidation which are the essential part of the vital function called respiration. The wise reader will compare the facts upon which we have been trying to insist with the statements made in the course on NATURAL HISTORY [page 135]. It is there stated that, unlike the growth of living things, the growth of a crystal "takes place by the addition of layers to the exterior, the interior remaining unaltered." The reader will see that the profound distinction there clearly stated is strictly consistent with the distinction which we have been trying to state here. He will guess that the reason why the living thing, unlike the crystal, can grow from within is the fact that it is able to undergo chemical changes, largely consisting of oxidation, within its very substance, and resulting, not merely in the "growth" of "crystals of sugar-candy on a string," but the true growth which implies development and the accomplishment of a purpose. It is its power of ensuring and directing intra-molecular oxidation that enables the living cell so to distinguish itself.

Ozone. When electric sparks are passed through oxygen—that is to say, ordinary gaseous oxygen—there is formed the allotropic modification of it, which is called ozone, and which has already been described [page 693]. Its formula, we may remember, is O_3; and, in confirmation of this statement, it may be noted that three volumes of oxygen have been proved to form two volumes of ozone, as one would expect, remembering the equation for the conversion of oxygen into ozone already given, and the remarkable law of Avogadro, that equal volumes of gases at an equal temperature and pressure contain equal numbers of molecules. Ozone may not only be produced by the method above stated, but also during electrolysis, and, in small quantities, in the course of very slow oxidation processes, as, for instance, that which occurs when ordinary phosphorus is exposed to the air. At sufficiently low temperatures ozone is transformed into a bluish liquid, closely resembling liquid oxygen. Ozone is, perhaps, the most inconstant of all the ingredients of the atmosphere. This is due to the fact that it is extremely unstable, for reasons that have already been fully explained. A sufficiently keen nose may recognise its peculiar odour, if its possessor goes out, for instance, into a very pure country atmosphere at night, after spending an hour or two in a smoky or badly ventilated room. In the open country, and at the seaside, ozone may readily be detected in the atmosphere ; but wherever there is a quantity of oxidisable organic material in the air—as, for instance, in towns and in their neighbourhoods—ozone is not to be found, since it is decomposed, and ordinary oxygen formed by the reducing action of such organic matter. In all probability ozone cannot be breathed, and is as irrespirable as if it had nothing to do with oxygen. The public generally believes that it is a good thing to breathe air containing ozone ; so it certainly is, but not in the smallest degree for the reason that the ozone is of itself of any value as a gas to breathe, but because its presence in air is *a proof that the air is pure*, the simultaneous presence of organic dirt (gaseous or other) and of ozone in air being impossible, owing to the great activity of this gas as an oxidising agent. Various medical experiments have been made in order to test the utility of ozone, and the statements above made may be regarded as accurately summing up the general conclusions to which those experiments lead. In cases of illness there is often very good reason to increase the percentage of oxygen in the air that the patient breathes, but the intentional addition of ozone to it is unnecessary, and depends on an incorrect explanation of the superiority of sea to town air. As we have observed, the presence of ozone in the former is of value, not in itself, but as an index and proof of purity.

The Atmosphere. By far the most important constituent of the atmosphere, from our point of view, is oxygen, though about four-fifths of it by volume is composed of nitrogen : the percentage of carbon dioxide is ·04. In addition, there is always a certain amount of water vapour, and traces of various compounds containing nitrogen. Until late years the foregoing would have been, more or less, an adequate account of the chemical composition of the air, but it is now known that the air contains a number of other gases which are of very considerable interest. If the air were a compound, the presence of these gases must have been detected long ago ; but since the air is not a compound, but merely a mixture of gases, it is easy to understand how the presence of these recently discovered gases, which occur in only very small quantities, came to be overlooked.

The Discovery of Argon. The initial discovery was made by Lord Rayleigh, who has recently been elected President of the Royal Society. In discussing this very interesting subject we shall follow very carefully the statements and, where possible, the actual words, of Lord Rayleigh himself. He was led to the now universally admitted discovery of the new gas *argon* in the course of some investigations regarding the densities of the most important gases—hydrogen, oxygen, and nitrogen. He found that different results were obtained by different methods of experiment, and it became apparent that the differences were not due to accident or errors of observation, but, as he says himself, " that the complication depended upon some hitherto unknown body, and probability inclined to the existence of a gas in the atmosphere heavier than nitrogen and remaining unacted upon during the removal of the oxygen." This was the means by which Lord Rayleigh, with the aid of Sir William Ramsay, the Professor of Chemistry at University College, London, was enabled to announce to the British Association in 1894 the discovery of a new gas in the atmosphere, though " for more than one hundred years before 1894 it had been supposed that the composition of the atmosphere was thoroughly known." This new gas was named *argon*, which is a Greek word meaning lazy, in order to indicate the fact that it is chemically very inert and has no tendencies to unite with any other substance. This chemical inertness of argon is, of course, one of the reasons why it was so long in being discovered. It is, perhaps, worth noting that certain chemists inclined to the view that argon is a sort of condensed nitrogen having the formula N_3, just as ozone, with the formula O_3, is a sort of condensed oxygen. But that view is entirely disproved. Argon is unquestionably an element, and possesses a very characteristic spectrum [see PHYSICS]. Its atomic weight, according to various investigations, is very nearly 40. So inert is this element that there is still no definite evidence of the preparation of any compound of it whatever, despite a very large number of attempts to produce such combinations.

More New Gases. This discovery, however, like so many others that have been at first questioned, has not only been established, but has led to many more, which stand to the credit of Sir William Ramsay. Argon, so long unknown, actually constitutes nearly one per cent. of the atmosphere. Contrast this with the tiny proportion of carbonic acid. But there have now been isolated from the original argon, so to speak, no less than four other elements, and probably five. The four of which we may be certain are called ***neon*** (Greek for new), ***krypton*** (Greek for hidden), ***xenon*** (Greek for stranger), and, by far the most interesting of all, ***helium***, the name of which is derived from the Greek word for the sun, and was given it for the reason that, as we already noted [page 839], this most remarkable element was discovered in the sun before it was found on the earth. Helium must be discussed at a much greater length when we come to consider a still more remarkable element, *radium*. The percentage of these gases in the air is extremely minute, and, according to Sir William Ramsay, probably the volume of all of them taken together does not exceed $\frac{1}{400}$th part of that of the argon. Now, the remarkable fact which is common to all these five new constituents of the atmosphere is that not one of them can be made to combine with any other substance whatever—in fact, they are all as " lazy " as argon. Each of them has its own characteristic atomic weight and spectrum, but we need not concern ourselves with these. The really interesting thing is the existence of these five elements, which seem, so to speak, to be isolated in Nature ; more especially because we have reason to believe in a *periodic law* which declares that all the elements are related to one another.

The New Gases and the Periodic Law. Now, one of the most important facts which are demonstrated by the periodic law is that the succeeding groups of elements show a regular progression in the number of atoms of other elements with which one of their own atoms is able to combine. This property is called *valency*, and will be considered later. For instance, group one of the elements includes those whose atoms are able each to unite with one atom of any other similar element. Hydrogen and sodium, for instance, belong to this group, and are hence called monovalent—that is to say, their valency is *one*. Oxygen, again, belongs to the second group, and its valency is *two*. The best illustration of what is meant is furnished by the formula of water, which is H_2O, indicating that it needs two " one-handed " hydrogen atoms, so to speak, to unite with one " two-handed " oxygen atom. This is enough to enable us to understand valency so far as we need at present. Now, what is to be done with a group of elements which are incapable of combining at all—elements which have no valency ? Plainly, if the periodic law be correct, they must form a group nothing, or zero, which must fit into the table with all the other elements. Now that is exactly what, indeed, these elements do : directly we discover their atomic weights, we find that they naturally fall into the very places which theory would have predicted for them, and they now form the *zero* group of Professor Mendeleeff's latest table, published in 1904.

For a consideration of a large number of other important facts concerning the atmosphere, the reader must consult the course on Physics. There is little more of importance to be said concerning the chemistry of the atmosphere, though very much that is a matter of life and death might be said if we were discussing the subject of ventilation [see PHYSIOLOGY and HEALTH]. The necessity for ventilation depends upon the fact that the presence of living things in the atmosphere alters its composition to their disadvantage, so that, if they do not move to fresher air, fresher air must be brought to them.

The History of the Atmosphere. If we recall the teaching of geology and astronomy, telling us how the earth was once too hot to sustain life, we shall see that the mixture of gases that covers the solid surface of the earth, and that we familiarly call the air, must have had a very interesting history. According to one widely accepted theory of the earth's origin, all that we now know as the solid earth, and all the liquid matter that now fills the ocean-beds, was once gaseous. The gases of the atmosphere are simply composed of those particular elements which are gaseous at the present temperature of the earth's surface, which have not entered into complete combination with the solid matter of the earth's crust, and which have not been whisked away into space by centrifugal force [see PHYSICS], this being the fate that is supposed to have befallen the former atmosphere of the moon, and some of the lighter constitutents of our own atmosphere. Now, in the past, when the earth's temperature was much higher, and when many other conditions were different, it is more than probable, for instance, that—long before man appeared—the proportion of carbon dioxide (CO_2) in the air was much higher than it is at present. This would account for the extreme luxuriance of vegetation, to which every lump of coal bears witness, the carbonic acid of the air being one of the most important constituents of the food of plants. Again, it is quite certain that, at a very much more remote period, which must certainly date back tens of millions of years, the temperature of the earth's surface was so hot that water could not occur in its liquid form. At that time one of the most important and abundant constituents of the earth's atmosphere was gaseous water, or water vapour.

The Future of the Atmosphere. Whatever the past history of the atmosphere may have been, we can scarcely fail to be interested in the question of its future, upon which the continued existence of the human race certainly depends. It seems at first sight quite evident that there is taking place a very serious, though admittedly very slow, change in the chemical composition of the atmosphere, depending upon the respiration of the countless living things, animal and vegetable, which depend upon it for their life. What is continuously happening day and night in the case of every living thing, without exception, including, for instance, the writer as he forms these words ? His body is undergoing a series of chemical interchanges with the atmosphere, the essential upshot of which is that the air around him becomes poorer in oxygen and richer in carbonic acid. Now this process of respiration and its consequences are common to every living thing, always and everywhere. Hence there appears to be no choice but to believe that the percentage of carbonic acid in the air is slowly increasing, and that of oxygen slowly diminishing. Meanwhile, the students of health remind us that when the percentage of carbonic acid in the air goes anywhere above ·06 such air becomes more or less poisonous to animal life in general, including the life of man. Are we then to believe that the carbonic acid is accumulating, and will continue to accumulate, gradually filling up the valleys and low-lying districts in consequence of its greater weight, and gradually driving human beings higher and higher, until the "last man," gasping for air on some mountain peak, joins his fellows who lie drowned in the sea of carbonic acid beneath him ?

A Compensatory Action. Now, in the first place, we must notice that there is a compensatory action, which is of considerable importance—namely, the action of the green plant, under the influence of sunlight, in decomposing the carbonic acid of the air, retaining the carbon and giving back to the air free oxygen again. This process, however, cannot suffice to dispose of the picture we have suggested, even apart from the fact that its value is largely neutralised, since even the plants that perform this function are also necessarily performing the opposite function of respiration. There is another fact of the very greatest importance, which is of only comparatively recent discovery, and which is of great importance to the theorist, and of incalculable importance in relation to the future of the atmosphere.

A Function of the Sea. In a previous chapter we briefly noted, in reference to the existence of double compounds, that the many salts of sea-water exist in a somewhat peculiar state. If we take a sample of sea-water and proceed to analyse it according to the usual methods, we find that it contains such and such a percentage of sodium chloride, another percentage of salts of magnesium, and so forth. Hence, we might suppose that these salts exist in definite form, and in definite proportion in sea-water ; but it is not so. We know now that the salts of sea-water mainly occur, not at all in definite states, but in states which constantly vary and differ, according to the physical conditions—conditions such as the temperature, the pressure of the atmosphere, the partial pressure of the various gases in the atmosphere, and, indeed, all the other physical conditions that occur. It is the new science of what is often called *physical chemistry* that is teaching us how exactly to correlate such physical conditions with the facts of chemical combination and union.

Now, if the reader remembers our former discussion of the carbonate and bicarbonate of calcium, and the formation of stalactites and stalagmites, he is already completely prepared to understand the most important function of the sea in regard to the composition of the atmosphere. He will remember how an extra proportion, so to speak, of carbonic acid is sometimes added to carbonate of calcium, converting it into the soluble bicarbonate, and how, under certain physical conditions, such as occur when water, charged with bicarbonate, drips through the roof of a cave, the extra carbonic acid is given off to the air, and the insoluble carbonate is precipitated or solidified from out of the water. Now, a parallel series of changes occurs in certain carbonates of sea-water, more especially the carbonate of magnesium. In sea-water there occurs a certain amount of this salt in a more or less stable state, and also a certain quantity of the bicarbonate of magnesium.

But, as we have already seen, there is reason to believe that the proportion which these two salts bear to one another in sea-water depends strictly upon the physical conditions which surround them, the most important of these conditions being the percentage of carbonic acid in the air above the sea [page 1159].

There is thus an automatic, self-regulating mechanism by which the oceans are enabled to preserve the constancy of the proportion of carbonic acid in the air above them, and not only so, but the winds, and that property of gases which we have described as diffusion [see PHYSICS], ensure that the consequences of this process extend also to the air of the land. Of course the discovery of this process is very far from enabling us to reach any positive conclusions as to the more immediate future of the atmosphere. It is evident that the mere absorption (in the form of bicarbonates in sea-water) of the extra carbonic acid which is being constantly added to the atmosphere by the respiration of all living things, and also by every kind of combustion initiated by man for his own purposes, is by no means equivalent to an absolute compensation for this process. All that it accomplishes is to hide the consequences of the process.

Tendency of Chemical Change. There is thus raised the further question, which cannot be considered here, as to the ultimate consequences of the fact that the overwhelming tendency of all the chemical processes that occur on the earth is in *one direction* — a direction which is well indicated by the union of carbon and oxygen to form carbonic acid. The essential consequence of this union is the dissipation of the potential chemical energy [see PHYSICS] of the carbon and of the oxygen in the form of heat energy or kinetic energy, which is scattered and, for practical purposes, lost, though, of course, it is not annihilated. Hence, in considering the future of the atmosphere, we are led on to the study of the remarkable and vastly important theory called by its author, Lord Kelvin, the theory of the *dissipation of energy*.

So much, then, for our chemical discussion of the atmosphere, of which, from our point of view, the oxygen is the essential constituent, the carbonic acid a source of some apprehension, and the large proportion of nitrogen merely a means of diluting the oxygen, which would otherwise be too active for our convenience. We have now to remind ourselves that, when the elements are considered in groups, there is good reason for considering sulphur and oxygen together, and we must therefore pass on to discuss this other important element.

ORGANS OF RESPIRATION

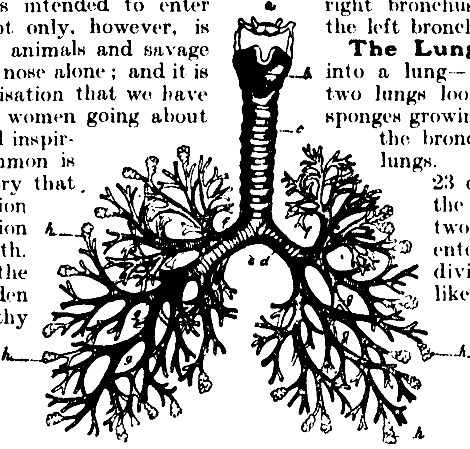
The Nose, Lungs, and Thorax. The Process of Breathing. Inspired and Expired Air. Production of Arterial Blood. Abnormal Breathing

By Dr. A. T. SCHOFIELD

THE respiratory organs include the nose, mouth, larynx, windpipe, lungs, and pleura, with the nerves and blood-vessels belonging to them.

The Nose. We are aware that the nose is not generally included in this category, and the omission has led to serious results. The sense of smell has been considered so exclusively the sole function of the nose that if any child were asked " What is your nose for ? " and it were to answer " To breathe with," the reply would create great astonishment. Yet this is undoubtedly the primary function of the nose, and all inspired air should pass through it. Indeed, it is because it is so designed that the olfactory organ is situated in the upper part to catch the odours the air may carry—a useless position if all the air is intended to enter through the mouth. Not only, however, is this not the case, but all animals and savage men breathe through the nose alone ; and it is only as a product of civilisation that we have the spectacle of men and women going about with the mouth open and inspiring through it. So common is the habit in this country that we found on investigation about half the population inspired through the mouth. Air breathed through the mouth is raw, cold, laden with germs and the filthy dust of streets and rooms, thus drying the tongue, destroying the teeth, causing sore throats and snoring, and clogging and poisoning the lungs.

Air breathed through the nose is warmed, moistened and cleaned so perfectly from all germs and filth, that not one microbe passes down into the lungs.



61. LARYNX, TRACHEA, BRONCHI
a. Hyoid Bone. b. Larynx. c. Trachea. d. Left Bronchus. e. Right Bronchus. f. Larger Bronchial tube. g. Smaller Bronchial tube. h. Cells of Lungs

The nose, therefore, is the first respiratory organ. Its passages are tortuous, and yet free, lined with stiff hairs to intercept foreign bodies, and with ciliated epithelium, that catches all the dust. An abundant blood supply keeps its passages warm, while a free secretion of mucus keeps the air moist. The posterior nostrils are twice the size of the anterior, and through them the air passes behind the soft palate down the larynx. The vocal cords, in a quiescent state, afford a free and silent passage for the air to and fro in breathing ; only when used for vocalisation is the passage of the air obstructed.

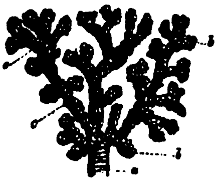
The top of the larynx can be closed tightly by a lid called the epiglottis, but it is never closed save just in the act of swallowing, when it shuts down as the tongue is carried backwards.

The mouth serves for expiration equally well with the nose, the special function of which is inspiration.

Passage of the Air. The air, then, enters by the nostrils (you can see how they act if you watch a horse breathing), and passes backwards through the posterior nares (nostrils) into the throat, and then down through the epiglottis, which is open, into the larynx, or voice box. The air, passing through the larynx, then enters the windpipe, which is called the trachea, because it feels rough outside on account of the 16 to 20 rings of gristle that surround it. This pipe is an inch in diameter, and 4½ in. long. Just behind the breast-bone it divides into the right bronchus (almost horizontal) and the left bronchus (almost vertical) [**61**].

The Lungs. Each *bronchus* runs into a lung—the two bronchi and the two lungs looking just like two huge sponges growing on two stout branches, the bronchi forming stalks to the lungs. The right lung, weighing 23 oz., is in three lobes, and the left, weighing 19 oz., is in two lobes. When the bronchi enter the lungs they rapidly divide and subdivide, exactly like the branches of a tree, until at last the twigs get very small (only one-fortieth of an inch in diameter). Each tiny twig then ends in an air-cell one-fiftieth of an inch in diameter, somewhat the shape of a grape, only the outside is *not smooth*, but like a raspberry or blackberry [**62**]. A bunch of these cells fixed on the little air twigs looks very like a bunch of grapes. When the air gets as far as this, its further progress is stopped. The outer sides of these air-cells are covered with such myriads of blood-capillaries that it is said that if those in the lungs alone were stretched out in one straight line they would reach from here to America. These capillaries differ from those in the body, for those brought food to the cells and took away the refuse ; they gave up all the fresh air from the corpuscles to the body-cells, and took away carbonic acid gas. These bring the bad air and take away the fresh. The red corpuscles that arrive here laden with carbonic acid gas, and of a dark colour, thus have them filled again with oxygen, and changed to a bright red colour. The walls of the capillaries and of the air-cells are so thin that the oxygen from the air can easily pass out of the cells into the blood, and the carbonic acid in the corpuscles can easily pass out of the blood into the air. All animals inspire oxygen and give out carbonic acid gas; and in all there are lungs, or the principle of a lung, which consists essentially of a thin membrane with air on one side, and blood in small thin vessels on the other. The gills of a fish, for instance, are formed on this principle. The water, with air dissolved in it, has free access on one side to a thin membrane on the other side of which the blood circulates.

The blood, thus purified, then returns by the four pulmonary veins to the left auricle of the heart. Both the bronchi, the bronchial tubes, and the windpipe are lined with *ciliated epithelium*, the hairs of which are always waving upwards towards the throat, and so pass up any grains of dust that may be breathed in.



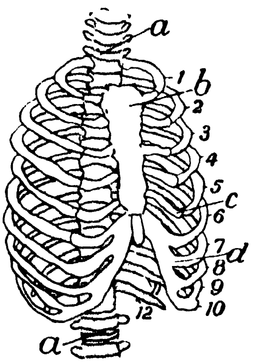
62. TERMINAL AIR CELLS OF LUNG

a. Small air tube. *b*. Terminal air cells. *c*. Smaller air tube

These bunches of air-cells, then, are all matted together by fibrous tissue, blood-vessels, and nerves, into the spongy substance we call lung.

The Pleura and Thorax. Covering each lung with the double folds of an empty bag, after the fashion of the pericardium round the heart, already described, is the pleura, right and left. The outer layer of the bag (the parietal layer) adheres to the inner side of the thorax or chest wall, lining it with a smooth and glistening membrane. The inner layer (the visceral) is equally adherent to the lung, which lies close against the chest wall. Between the two layers is a little fluid that lubricates the two surfaces and enables the one to glide upon the other in the incessant movements of respiration, without friction and without noise, thus performing the work of a universal joint.

So much, then, for the structure of the respiratory organs. The thorax itself [63], which is filled by the heart and lungs, and large vessels, consists of a dome-shaped cavity, closed in at the top by the ribs and fleshy part, the only opening into the lungs being through the windpipe. Its back is formed by the spinal column, its movable sides by the ribs, which are each jointed behind to the backbone, and the upper seven pair in front to the breastbone. The next three are each joined by cartilage to the pair above them, whilst the last two are free in front. The lungs are thus shallow in front (down to the 6th ribs), and deep behind (down to the 11th) The floor of the thorax is formed by a strong muscle (the diaphragm) stretching right across the body, slanting downwards behind, through which the blood-vessels and gullet pass.



63. THE BONES ENCLOSING THE THORAX

a. Vertebral column: 1-12. Ribs. *b*. Sternum. *c*. Costal cartilages. *d*. United cartilages of upper false ribs. 11 and 12. Floating ribs

Mechanism of Respiration. We will now proceed to consider the mechanism, muscular and nervous, of respiration. The force expended in opening the chest in inspiration each day is enough to raise the person the height of St. Paul's, and is thus only about one-sixth of the force spent in the circulation. The surface of blood that is exposed to the air [64] at each breath in the thin film in the capillaries outside the air-cells is equal to about fifty-six square yards.

Breathing consists of two acts—*inspiration* and *expiration*. *Inspiration* is a *forced muscular effort* performed by *three* distinct sets of muscles—those that act on the ribs, those that act between the ribs, and the diaphragm, which is the floor of the thorax.

In inspiration *the chest-cavity* is made broader, longer, and deeper. When at rest, the ribs, hinged behind to the backbone and in front to the breastbone, hang down like the iron handle on the side of a bucket. Now, if you raise such a handle, it not only moves upwards, but outwards. The same takes place with the ribs—and, in addition, the sternum, or breastbone, being movable, rises forwards as well, and thus the chest is made *broader* and *deeper*. It is made *longer* because, when at rest, the diaphragm muscle forms an arched floor, that rises like a dome into the thorax, and on which the lungs rest. As this muscle contracts it flattens the floor, pulls the lungs down, and so makes them longer from top to bottom.

The muscles that raise the ribs are in two sets—those that act on the ribs and those that act between them. The upper ribs are pulled upwards by muscles passing down from the neck.

Between each rib is a double layer of muscles, crossed like an x; they are called the intercostal muscles, because they are between the ribs [65]. The top ribs being fixed as these contract, they tend to raise the lower rib, to which they are attached; and thus, by acting together, all the ribs are elevated.

This constitutes the movement of Inspiration.

In Expiration, *the chest returns to its original size* without effort. This is mainly caused by *elastic recoil*. The lungs are full of elastic tissue, which is stretched when the lungs are expanded; and, as soon as the muscular effort ceases, the elastic force is so great that the lungs pull the ribs down again, and pull up the floor of the diaphragm [66].

You will notice when you draw in a breath that the abdomen swells out. This is caused by the contraction of the diaphragm, which presses all the digestive organs down and makes them bulge out the walls. In expiration the abdomen gets flat again, as the floor rises once more.

The force required to stretch out the elastic tissue in ordinary inspiration is equal to 170 lb.; and the total daily force used in respiration is 21 foot tons.

The Nervous Mechanism. The nervous mechanism of respiration is of great practical interest. There are two great centres in the brain where respiration is controlled—the one in the Conscious region, under the control of the will, and hence voluntary; the other in the Unconscious region, involuntary, and governed by the unconscious mind.

The Muscular Mechanism. The movement of the muscles is controlled from these centres by various nerves, notably the pneumo-gastric.

Practically our breathing is under our own control up to the point where life is involved. We can breathe in any manner and at any rate we please. Were it not so, speaking would become impossible. We can also hold our breath up to a certain point; but when life is beginning to be threatened the other involuntary centre comes into play, and, in spite of the strongest effort of will, forces us to breathe. This is a merciful and necessary provision to safeguard us against our own folly, and is paralleled by many similar facts in protective physiology. As it is, suicides are far too common; but imagine the loss of life, if every time one were vexed or desperate and wished to die one had only to lie back in a chair or bed and hold one' breath! Why, thousands would die every week. But this is not possible on account of the unconscious control of respiration. This control also acts continuously when we we are not thinking of our breath at all. None of the vital processes require our constant attention; yet with some we are allowed to play up to the point of danger, but no farther.

Respiration of Men and Women. We now come to consider different types of respiration, a matter of great interest.

It has always been observed that the sexes breathe differently, and it has been thought, and laid down in text-books, that the difference is a part of the many distinctions between men and women.

Children of both sexes up to puberty were observed to use all their ribs in expansion, and the diaphragm by descending in inspiration. But from this age the types began to diverge. Girls and women breathed increasingly with ribs only, the diaphragm remaining stationary, and very many women with the upper six pairs of ribs only. Men, on the other hand, tended to breathe less with their ribs, and more by descent of the diaphragm.

It is now discovered that this variation is chiefly due to the difference of dress, and that if a woman be always dressed as a man she breathes in the same way. Diaphragmatic breathing involves a change of two or three inches in the circumference of the waist, and when this is enclosed in a rigid dress-band somewhat smaller than the least waist size (to say nothing of corsets), it is evident that movement of the diaphragm becomes impossible. If the corsets be at all rigid, the lower ribs also become fixed, and the whole strain of respiration is then thrown on the upper half and most delicate part of the lungs, the place indeed where consumption almost invariably begins; while the stationary lower half is a favourite seat of congestion. This is bad enough in quiet life, but in active exercise, such as games and dancing, it becomes positively dangerous.

Man, on the other hand, having never had a rigid waistband, breathes abdominally, and does not move the ribs so much, as all hard work with the arms requires the chest wall to be more or less rigid.

Of course the reason why the waist expands so in abdominal respiration is because the descent of the diaphragm presses down the viscera and bulges out the walls. Hence, in those accustomed to breathe thus, when there is any distension in the abdomen, the breath gets embarrassed because the diaphragm cannot descend.

Changes in Respired Air. We must now consider the air that is respired. We only take our solid and liquid meals three or four times a day; our air-meals, or breath, we have to take 17 times a minute! The air we breathe (if pure) consists of one part of oxygen and four parts of nitrogen, with just the least trace only of carbonic acid gas. The nitrogen is only used to *dilute the oxygen*, as water is used to dilute brandy, for the oxygen would be too fiery without it. Oxygen supports combustion, and enables all substances to burn, but will not burn itself. The heat of the body is kept up entirely by a process of slow combustion. Rapid combustion produces a *flame*, as when gas burns in air; slow combustion produces *smouldering*, as in the end of a match or cigar, or a red-hot poker. But there is a slower combustion that only produces *heat*, as when a little sulphuric acid (oil of vitriol) is poured into a glass of water. There is no flame or burning, but the water gets quite warm. This is the sort of combustion that takes place in the body.

Oxygen not only keeps up the fires of life; it also renews the material. All the body-cells continually need it to repair their tissues, and here also it is slowly used up.

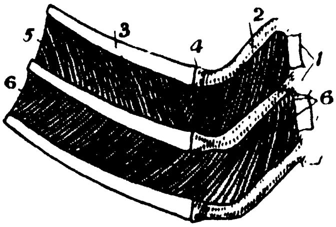
Respiration goes on, however, not only to supply the body with oxygen, but to get rid of the carbonic acid and water that is produced by the combustion and the waste of the cells. The solid part of cell-refuse is called urea, and is carried off in the urine by the kidneys, together with a great deal of the water; but all the gas and part of the water are carried off by the lungs in the process of respiration. The skin does a little respiration also—about $\frac{1}{150}$th part of that done by the lungs.

Good Air. It is of the utmost importance that the air we breathe should be pure. The food we take has often to be brought great distances to get it good and pure, but we are always obliged to breathe the air that is close around us; so we should never live or sleep in close, impure, unventilated rooms. If we do, we cannot be healthy, for we cannot get pure air to breathe.

If we breathe the air in a room where a number of people are crowded together, it is not only full of *poisonous carbonic acid gas* from their breath, but full of *decaying particles of animal matter* given off from the skin and lungs of so many people.

The air we inspire, as a rule, is fairly *dry, cool,* or *cold;* is full of *dust*, and other particles, and is composed of *one part of oxygen and four parts of nitrogen.* The air is drawn into the lungs by their being stretched out and made so much larger by muscular effort that a vacuum is produced, and the air rushes in to fill the space.

The amount of air taken in at an ordinary breath is 20-30 cubic inches. This is called *tidal air*, for it goes in and out like the tide. If you take a very deep breath, you can draw in 100 cubic inches more, which is called *extra*, or *complimental air.* Now, when you have expired this and the tidal air, if you breathe out very hard you can expire another 100 cubic inches of air, called *reserve air*, and then, when the last particle of air has been breathed out, there still remain, far down in the air-cells, 100 cubic inches of fixed or *residual air* that never leaves the lungs.



65. THE INTERCOSTAL MUSCLES

1. Sternum. 2. Cartilages. 3. Ribs. 4. Junction of ribs with cartilages. 5. External intercostal muscles. 6. Internal intercostal muscles (laid bare on the left)

You will easily understand that if the lungs hold ordinarily 230 cubic inches of air, and can be made to hold 330, the 30 we breathe in and out only just moves the air in the larger tubes, and never reaches the air-cells at all.

The wonder, then, is how the fresh oxygen ever gets to the blood if the air-cells and smaller tubes are always filled, as the depths of the ocean are with water, with an air that never moves. This is due to the law of diffusion of gases, by which any two different gases brought together at once change places.

When we draw a breath in, charged with pure oxygen, the fixed air beneath in the cells, full of carbonic acid from the blood, at once gives up this gas in exchange for the oxygen, while the nitrogen never moves at all. Were it not for this law, fresh air would never reach the blood at all. We quite understand that carbonic acid gas is not made in the lungs, but all over the body, and all that takes place in the lungs is its exchange for oxygen.

Expired Air. Expired air differs in every way from inspired air. The analysis of the two is as follows:

Inspired Air:		Expired Air:	
		Ammonia and org. salts	·4
CO_2	·04	CO_2	4·1
N	79·15	N	79·5
O	20·81	O	16
	100·0		100·0

In short, four parts of oxygen are replaced by four of CO_2.

Expired air is *hot*, about blood-heat, *full of water*, contains *no dust*, but much *decaying animal matter*, a considerable amount of *carbonic acid gas, less oxygen, and the same amount of nitrogen.*

You can prove this by experiments:

1. *To show it is hot.* Breathe on the bulb of a thermometer, and you will see it will rise to about blood-heat.

2. *To show it is full of water.* Breathe on a cold looking-glass, or the blade of a steel knife, and you will see it is soon covered with drops of water. When the air is cold, you can actually see the water vapour coming out of your mouth or a horse's nostrils.

3. *To show it contains carbonic gas.* Buy a little lime-water, or make it by mixing quicklime with water, letting it stand, and pouring off the clear fluid, which is lime-water.

If you breathe through a piece of tube into this water it will soon become milky, owing to the forming of chalk, which is carbonate of lime, and is made by the carbonic acid of the breath uniting with the lime in the water.

About half a pint of water and half a pound of solid carbon passes out by expiration each day, as well as a great deal of body heat. These amounts increase during life from 1 to 30, remain stationary from 30 to 50, then slowly decrease. The CO_2 expired varies in proportion to the amount of muscle waste from work done.

With quick breathing, rise of temperature, and in the autumn, the CO_2 is less. In the spring, and under opposite conditions, it is more.

Of 100 parts of CO_2 daily expired, 52 parts are expired in 12 hours during the day, and 48 in 12 hours at night.

Of 100 parts of O inspired, 33 parts are absorbed in 12 hours during the day, and 67 in 12 hours at night. This shows that it is more important that the air breathed at night be pure than the day air, contrary to what is generally supposed. In exercise one-third more air is required.

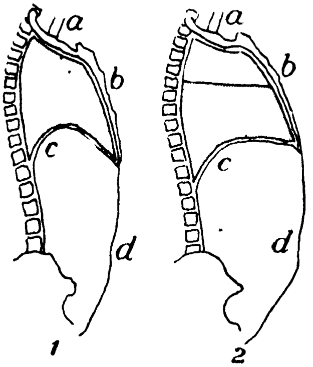
How Arterial Blood is made. We must now describe the changes effected in the blood by respiration.

The venous blood, laden also with organic refuse from the tissues and from the lymphatics, arrives at the lungs through the pulmonary artery from the right heart, and is spread out in the finest capillaries on the outside of all the air-cells. There, not by mere filtration, but by what is believed to be some vital action of the air-cells, a little over 4 per cent. of CO_2 is introduced into the air together with about ·4 of effete animal matter and ammonia out of the blood, while to keep the balance, a corresponding amount of O is introduced with the blood, with the effect of at once making it bright scarlet.

The following experiments will illustrate the way in which the change between the two gases takes place in the lungs:

1. If blood is allowed to run from a vein, and form a clot in a plate or saucer, the outside of it will be seen to become bright red, because the carbonic acid passes into the air, and the oxygen takes its place. But underneath, or inside, it remains quite dark, and if you suddenly turn it over, you see this, though the dark part soon becomes bright when exposed to the air.

2. If you get a little bright blood in a moist bladder and hang it in a jar of carbonic acid gas, it gets purple. If you now hang it in the air in a jar of oxgyen, it gets bright red again, showing that the gases can pass through the walls of the bladder as they pass through the air-cell membrane. Such, then, is the normal process of respiration; but various abnormal processes occur.



66. FORM OF THE STERNUM, DIAPHRAGM, AND ABDOMINAL WALL IN (1) EXPIRATION, (2) INSPIRATION

a. Trachea. b. Sternum. c. Diaphragm. d. Abdominal wall. The dotted portion represents the stationary air

Abnormal Respiration. *Dyspnœa*, or difficulty of breathing, culminating in breathlessness, is due rather to deficient oxygen rather than excess of CO_2, as is shown by experiment. But at times, as in breathlessness caused by excessive exertion, as from running races, it is caused by the CO_2 from the used-up tissues accumulating faster than it can be got rid of.

Apnœa, or ceasing to breathe, occurs at death, and also temporarily after several rapid inspirations.

Asphyxia follows failure in the supply of oxygen. There is first exaggerated breathing, then convulsions, then exhaustion and death. The blood accumulates in the right heart, and becomes venous all over the body.

Excess of CO_2 does not produce asphyxia, but narcotic poisoning.

Ordinary expiration is quite quiet, because the larynx is kept widely open, and the two bands known as the vocal cords are far apart. If they are brought together, however, some sort of sound is made in expiration. Talking and singing, groaning, laughing, coughing, all take place in this way.

Sound is only formed in the larynx, words are made in the mouth. In laughing the breath comes out in a series of explosions; coughing is very similar. The breath seems to burst open the vocal cords. Indeed, the two are so much alike that if a person laughs and coughs at the same time it is hard to tell the one from the other.

Sighing and gaping are two special forms of inspiration we will explain here. If from any cause insufficient oxygen is getting into the blood, as, for instance, when a boy is sitting writing or studying, and breathing very gently for a long time, the nerve-centre that controls the breathing sends an impulse to fill the lungs with fresh air, and he heaves a sigh, which is thus an effort of Nature to get enough oxygen. Panting is an effort made for the same reason.

Yawning is a still more determined effort of Nature to get all possible air into the lungs. The head is thrown back to open the larynx to its fullest extent, the nostrils and mouth are both widely opened, and all the muscles are used; the arms are extended, and the body is thrown back so as to stretch out the lungs to the greatest possible size, and thus supply the blood with plenty of oxygen.

Hiccough, coughing, sneezing, sniffing, sobbing, laughing, sucking, are examples of various forms of inspiration and expiration of special character and for other purposes than ordinary respiration.

POETRY OF THE NINETEENTH CENTURY

1. A Biographical and Critical Survey of the Poets of Last Century before Tennyson, and the Influences on their Work

By J. A. HAMMERTON

THE poetry of the nineteenth century has its roots in the work of the eighteenth century. Its branches stretch forward into the century that is yet in its infancy. In its style, a notable characteristic is a certain reaction against artificiality and mere rhetoric. In the spirit of it is distinguishable the influence of the Germany of Goethe and Schiller; of the France of Rousseau and Victor Hugo; and of the "problem" writers of Norway and Denmark. The movements toward political freedom in France, Italy, and Greece, and the evolution of English democracy have all affected it vitally. Thus, to its understanding must be brought some knowledge of the historic happenings amid which it arose and flourished.

It is possible to take the works of two or more of the greatest poets of the period, and to derive pleasure from the isolated perusal of them. But while there is much to be said for the study of the poetry of any writer for its own sake, too general a neglect of "books about books" is certainly to be avoided. The more we know of the main facts in the life and times of a great writer, the better shall we understand and appreciate what he has written. It is "the man behind the book" we are interested in, as Carlyle pointed out. So far as the poets and poetry of the nineteenth century are concerned, there is no lack of adequate guidance. The field is a wide one, and its flowers and fruits are varied. In all, something like two hundred names claim consideration. Of these, however, three or four are of outstanding importance; and rather less than thirty need engage those to whom poetry does not make a very strong appeal. Before taking up the study of any one of these writers, the reader could hardly do better than glance at the names in such a series as the "English Men of Letters," and, selecting the monograph dealing with the author he purposes taking up, make this the groundwork or starting-point of the study proper.

The Forerunner of Wordsworth. GEORGE CRABBE (b. 1754; d. 1832) is a particularly interesting figure to readers of the SELF-EDUCATOR. He was, to a very considerable extent, self-taught. In his verse, says Canon Ainger, "pity appears, after a long oblivion, as the true antidote to sentimentalism. The reader is not put off with pretty imaginings, but is led up to the object which the poet would show him, and made to feel its horror." The horror Crabbe chose to describe was that of the sordid side of English village life as he witnessed it in his native Suffolk.

Influenced by Gray, Goldsmith, and Pope, Crabbe is spoken of as the chief founder of the rural school, and as the forerunner of Wordsworth. He applied the lash to the ignoble rich as well as depicted with graphic realism the lot of the ignorant poor. We read Crabbe for what he says more than because of his style, which is unequal and frequently faulty. His knowledge of humanity is extensive; but he lacks both fancy and a sense of humour.

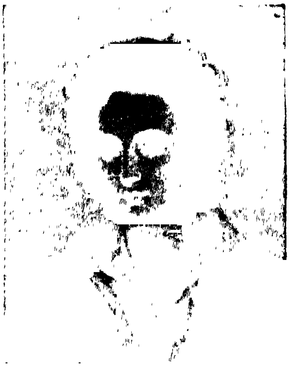
A Group of Lesser Poets. WILLIAM GIFFORD (b. 1756; d. 1826) was a shoemaker's apprentice. A giant, he used his strength like a giant. His two satirical poems, "The Baviad" and "The Mæviad," crushed out of existence the insipid poetry of the so-called "Della Cruscan School"; and to him is generally, but erroneously, attributed the "Quarterly Review's" famous (or infamous) attack on Keats's "Endymion," which was the work of J. W. Croker. He translated "Juvenal" and edited some of the old dramatists. WILLIAM BLAKE (b. 1757; d. 1827) is a link between the Elizabethans and Wordsworth. His love of children speaks to us in his "Songs of Innocence," his feeling of horror at the bitter side of life in his "Songs of Experience." He was a mystic, with something of the contrast of simplicity and subtlety in his work that is characteristic of Browning's poems; and he felt keenly and expressed keenly social wrongs and ecclesiastical tyranny. Like Crabbe, he had to fight poverty, and owed his knowledge to his own efforts towards self-improvement. Like Crabbe, he is again becoming popular; but perhaps his most enduring fame rests upon his skill as an artist. SAMUEL ROGERS (b. 1763; d. 1855), that "grim old *dilettante*, full of sardonic sense," as Carlyle called him, wrote a long poem in heroic metre on "The Pleasures of Memory," and caught, in his blank verse poem, "Italy," some of the beauties of that southern land. He had the wisdom to decline the Laureateship. ROBERT BLOOMFIELD (b. 1766; d. 1823), first a rural "hand" and then a shoemaker, wrote, in a London garret, "The Farmer's Boy," which gives a sympathetic view of the life indicated by its title. He derived his style from Thomson's "Seasons." Another poet of nature and the poor, though on a much higher level, is JAMES HOGG (b. 1770; d. 1835), the "Ettrick Shepherd," who stands next to Burns in the order of Scotland's peasant-poets. He described himself to Scott, to whom he sent contributions for the latter's "Border Minstrelsy," as "King of the Mountain and Fairy School of Poetry," and this piece of self-description is accepted by the critics. "When the Kye Come Hame" and "Kilmeny" (the last-named from "The Queen's Wake," a series of legendary tales and ballads supposed to have been sung by the Royal bards at Holyrood) are among Hogg's most popular, and deservedly popular, compositions. There is more that is enduring in the poetry of Hogg than in that of any of the others we have named since Crabbe, and the general reader, no less than the student, must devote considerable attention to his works, though his prose writings need not engage any but the student.

WILLIAM WORDSWORTH

Wordsworth's Life. WILLIAM WORDSWORTH (b. 1770; d. 1850) is one of the greatest poets of the nineteenth century. Indeed, his influence, which was of slow growth at the outset, is growing yet. He came of an old-established family, and in his early days was greatly influenced by the ideals of French Republicanism and the teaching of William Godwin, the author of "Political Justice," a work basing morals on necessity, who also had a marked influence on Coleridge. When France, having first debased them, forsook her humanistic ideals for dreams of world conquest under Napoleon, the effect on Wordsworth would have been disastrous but for the devotion of his sister Dorothy and the fact that a legacy of £900 left to the brother and a sum of £100 bequeathed to the sister enabled them to settle down quietly, first at Racedown, in Dorset—where Wordsworth's one tragedy, "The Borderers," was written—then to Alfoxden, by the Quantock hills—which district inspired his and Coleridge's contributions to the volume of "Lyrical Ballads"—and, finally, at Grasmere. This was the home of the Wordsworths from 1799 till the poet's death, the three places of residence there being Dove Cottage, Allan Bank, and Rydal Mount respectively. "The Prelude; or, the Growth of a Poet's Mind," an autobiographical poem in blank verse, reflects the influence of Continental travel—Wordsworth visited Germany, Italy, and Switzerland as well as France—and the philosophical views of Godwin. That poem and "The Excursion" are parts of a scheme which was never completed.

JOHN KEATS

LORD BYRON



P. B. SHELLEY

S. T. COLERIDGE

Wordsworth as a Critic. Wordsworth has to be considered in three aspects—as a critic, as a teacher, and as a poet. His critical opinions may be studied in the preface and appendix to the "Lyrical Ballads," the preface to "The Excursion," and in numerous letters. In the preface to the "Lyrical Ballads" he writes as follows: "It may be safely affirmed that there neither is, nor can be, any essential difference between the language of prose and metrical composition. We are fond of tracing the resemblance between poetry and painting, and accordingly we call them sisters; but where shall we find bonds of connection sufficiently strict to typify the affinity betwixt metrical and prose composition? They both speak by and to the same organs; the bodies in which both of them are clothed may be said to be of the same substance, their affections are kindred and almost identical, not necessarily differing even in degree." Pursuing the same idea, he writes in the appendix to the "Lyrical Ballads" that "metre is but adventitious to composition," and that "the phraseology for which that passport is necessary, even where it may be graceful at all, will be little valued by the judicious."

The best proof of the error inherent in the view of poetry thus set forth, which runs counter to all we agreed upon at the outset of this course, is to be found in Wordsworth's own work. Elsewhere, in his intense scorn for the artificial and the meretricious, which were so characteristic of much of the poetry of the eighteenth century, Wordsworth went to the verge of the trivial. But though he raised a storm of criticism, which delayed due recognition of his surpassing genius and is not yet exhausted, it is well to remember with Coleridge, one of the greatest of literary critics, especially where Wordsworth is concerned, that but for the prefaces and appendices much of what has been said against Wordsworth's poems would be reduced to absurdity. The few pages that gave such an opportunity to the pungent parodists of "Rejected Addresses," to Byron, to Leigh Hunt, to Jeffrey, and to others to pour scorn on Wordsworth, would, but for the fear that they represented an intention to overthrow the accepted canons of art, have been "passed over in silence as so much blank paper, or leaves of a bookseller's catalogue," and "only regarded as so many light or inferior coins in a rouleau of gold."

The Teaching of Wordsworth. As a teacher Wordsworth expressed his purpose to be: "To console the afflicted, to add sunshine to daylight by making the happy happier, to teach the young and the gracious of every age to see, to think, and feel, and, therefore, to become more actively and securely virtuous." It will be seen from this he took his vocation seriously. "The poet," he averred, "is a teacher. I wish to be considered as a teacher or as nothing." What did he teach ? George Brimley, in one of the most brilliant of his essays, written in 1851 and still applicable, contends, with reason, that the value of Wordsworth's teaching "lay mainly in the power that was given him of unfolding the glory and the beauty of the material world and in bringing consciously before the minds of men the high moral function that belonged in the human economy to the imagination, and in thereby redeeming the faculties of sense from the comparatively low and servile office of ministering merely to the animal pleasures. . . . He has shown the possibility of combining a state of vivid enjoyment, even of intense passion, with the activity of thought and the repose of contemplation. He has, moreover, done more than any poet of his age to break down and obliterate the conventional barriers that, in our disordered social state, divide rich and poor into two hostile nations ; and he has done this, not by bitter and passionate declamations on the injustice and vices of the rich, and on the wrongs and virtues of the poor, but by fixing his imagination on the elemental feelings, which are the same in all classes, and drawing out the beauty that lies in all that is truly natural in human life."

The Poetry of Wordsworth. Was Wordsworth a poet ? Indubitably ; as Plato and Dante were poets. None but a great poet could have written such lines as these from the poem "Composed a few miles above Tintern Abbey," in 1798 :

"For I have learned
To look on Nature, not as in the hour
Of thoughtless youth ; but hearing oftentimes
The still, sad music of humanity,
Nor harsh, nor grating, though of ample power
To chasten and subdue. And I have felt
A presence that disturbs me with the joy
Of elevated thoughts ; a sense sublime
Of something far more deeply interfused,
Whose dwelling is the light of setting suns,
And the round ocean, and the living air,
And the blue sky, and in the mind of man :
A motion and a spirit, that impels
All thinking things, all objects of all thought,
And rolls through all things."

Let the student who seeks to find Wordsworth at his best also ponder the exquisite ode entitled "Intimations of Immortality from Recollections of Early Childhood." But Wordsworth's claim to rank among the immortals might be based on his sonnets alone. From whatever standpoint it may be looked at, the sonnet "Composed upon Westminster Bridge, September 3rd, 1802," is one of the finest in the language :

"Earth has not anything to show more fair.
Dull would he be of soul who could pass by
A sight so touching in its majesty.
This city now doth, like a garment, wear
The beauty of the morning ; silent, bare,
Ships, towers, domes, theatres, and temples lie
Open unto the fields, and to the sky,
All bright and glittering in the smokeless air.

Never did sun more beautifully steep
In its first splendour, valley, rock, or hill ;
Ne'er saw I, never felt, a calm so deep !
The river glideth at his own sweet will.
Dear God ! the very houses seem asleep ;
And all that mighty heart is lying still ! "

There is nothing in the Elizabethan writers of the sonnet to surpass the above in perfection of form. Tennyson never wrote more truly nor with finer insight than when, in Wordsworthian phrase, he declared that the Laureate's wreath came to him.

"Greener from the brows
Of him who uttered nothing base."

It is unnecessary to urge Wordsworth upon the general reader, for he is so securely a popular classic that his poetry is in no danger of neglect.

Coleridge. Chief of Wordsworth's contemporaries was SAMUEL TAYLOR COLERIDGE (b. 1772 ; d. 1834). Coleridge was a talker, a preacher, a philosopher and a mystic. His best work belongs to his early years, when he was inspired by his love of nature and by the revolutionary idealism of France, and when, with Southey and Robert Lovell, he planned the foundation of a Utopia "in the rich heart of the West." Unhappily, all through his life, plans came more easily to him than performance. His life story is one of the saddest in English literary history. His health was poor, and his habits were worse. It is a notable fact that his ballad epic of "Christabel," though a fragment, exercised in MS. form, some twenty years before it was published, a wonderful influence on Scott and other contemporary English poets. "In this weirdly beautiful creation," says one critic, "the spiritual and material are so exquisitely blended that it is difficult to know where they run into each other." For an explanation of the dreamland beauty of "Christabel" and the "Rime of the Ancient Mariner" recourse must be had to the German philosophers, particularly to Goethe, Herder, Schelling, and others of their school, to whom Coleridge was much indebted. Mr. Swinburne says of "The Ancient Mariner" that it is "perhaps the most wonderful of all poems. In reading it we seem rapt into that paradise revealed by Swedenborg, where music and colour and perfume were one, where you could hear the hues and see the harmonies of heaven. For absolute melody and splendour it were hardly rash to call it the first poem in the language." Even so, Coleridge may prove a difficult poet for all save the advanced student and the genuine lover of poetry.

Scott and Tannahill. Sir WALTER SCOTT (b. 1771 ; d. 1832), on the other hand, is essentially a poet for the young. Repelled by the Revolution from visions of the future, he sought and restored to letters the romance of the past. "The Lay of the Last Minstrel," "Marmion" and "The Lady of the Lake," his best poems, are for the million what "Christabel" and "The Ancient Mariner" are for the comparatively few. For pure joy in nature and love of humanity Scott was not excelled by either Wordsworth or Coleridge, though there is a certain mechanical touch in his verse and a mannerism which prevent its being classed with the greatest English poetry.

Another Scots poet, and one of the greatest of song writers, was ROBERT TANNAHILL (b. 1774 ; d. 1810), a Paisley weaver, whose life was sad and ended tragically. His "Braes o' Gleniffer" and "Jessie, the Flower o' Dunblane" are favourite lyrics with Scotsmen the world over, and are assured of immortality.

Southey and Landor. ROBERT SOUTHEY (b. 1774 ; d. 1843), as a poet, is little honoured to-day, though Mr. Saintsbury boldly champions his cause. His change from a democratic to a Tory standpoint (exemplified in the difference between "Wat Tyler" and "The Vision of Judgment") may have had some influence on popular taste ; but his choice of subjects is perhaps the chief reason of the neglect into which he has fallen. Of his longer works, "Roderick, the Last of the Goths" is the best. The others are "Thalaba, the Destroyer," a rhymed epic of Arabia ; "Madoc," a semi-historical poem, descriptive of the adventures of a Welsh prince ; and "The Curse of Kehama," a poem in irregular rhymes, the theme of which is drawn from Hindu mythology. Southey is better known by such spirited ballads as "The Battle of Blenheim," "The Well of St. Keyne," and "The Inchcape Rock." The name of WALTER SAVAGE LANDOR (b. 1775 ; d. 1864) recalls one of the most touching stories in the romance of reality. It is told with exquisite sympathy by Sir William Hunter in the introductory chapter of his "Thackerays in India." Midway in the impetuous rush of his stormy youth Landor found kindness in the family of Lord Aylmer, with whose gifted daughter Rose he fell in love. The affection was mutual. It was Rose Aylmer who lent him the book which inspired the work—"Gebir"—in which his genius first flashed out into enduring flame. Hope told a flattering tale, and then Rose Aylmer was sent out to relatives in Calcutta, there to find an early grave. For days and nights her image never left Landor's brain. "During hours of sleeplessness he wrote the elegy which enshrines in a casket of pearl the name of Rose Aylmer as long as maiden hearts shall ache and the English language endure" :

> "Ah, what avails the sceptred race ?
> Ah, what the form divine ?
> What every virtue, every grace ?
> Rose Aylmer, all were thine.
> Rose Aylmer, whom these wakeful eyes
> May weep but never see,
> A night of memories and of sighs
> I consecrate to thee."

Landor gave a marked impetus to the Romantic movement, and while he is more for the student than for the general reader, the latter must make some acquaintance with his poetry and his prose. The poems of CHARLES LAMB (b. 1775 ; d. 1834) are chiefly valuable as expressions of his gentle nature.

Campbell and Moore. THOMAS CAMPBELL (b. 1777 ; d. 1844) is, like Southey, best remembered by his lyrical poems—"Hohenlinden," "Ye Mariners of England," "The Soldier's Dream," "Lord Ullin's Daughter" and the "Song of the Evening Star," are among them. His "Pleasures of Hope" is an echo of Thomson and Gray. THOMAS MOORE (b. 1779 ; d. 1852), who wrote "Lalla Rookh" and many songs to old Irish airs, had in abundance the double gift of vocal and poetic melody. His poetry, said Jeffrey, was as the thornless rose ; "its touch of velvet, its hue vermilion, and its graceful form cast in beauty's mould." "To me," said Byron, "some of Moore's last Erin sparks—'As a Beam o'er the Face of the Waters,' 'When he who Adores thee,' 'Oh, Blame not the Bard,' 'Oh, Breathe not his Name,' are worth all the epics that ever were composed." But Moore possesses claims in addition to those dependent on the charm of his "Irish Melodies." His latest critic, Mr. Stephen Gwynn, remarking on the increasing virtuosity shown during the nineteenth century in the management of lyric metres, says : "From Cowper and Crabbe to Mr. Swinburne is a strange distance ; and it has not been sufficiently realised that Moore is very largely responsible for the advance. Many critics have noted the change from the strictly syllabic scansion of Pope's school to metres like those of Tennyson's 'Maud,' and a hundred later poems, in which syllabic measurement is wholly discarded. It has been noted also that, even in the freer metres of the sixteenth and seventeenth centuries, lyric writers confined themselves to variations of the trochee or iambic, and that an anapæstic or dactylic measure is hardly found before Waller. But it has been hardly recognised that till Moore began to use these triple feet no poet used them with dexterity and confidence. . . . It is Moore's great distinction that he brought into English verse something of the variety and multiplicity of musical rhythms." Five other poets call for brief mention here :

Other Contemporaries of Wordsworth. EBENEZER ELLIOTT (b. 1781 ; d. 1849), whose "Corn Law Rhymes" have served to distract attention from his transcripts from Nature ; WILLIAM TENNANT (b. 1784 ; d 1848), whose poem of "Anster [Anstruther] Fair" was modelled on an Italian style, which Byron adopted for "Beppo" and "Don Juan," and thus definitely acclimatised ; LEIGH HUNT (b. 1784 ; d. 1859), whose reputation, largely due to his prose writings, would not be inconsiderable were it based only on "The Story of Rimini," and his other and shorter poems, of which "Abou Ben Adhem," and "Jenny Kissed Me" are most familiar ; THOMAS LOVE PEACOCK (b. 1785 ; d. 1866), who wrote a number of delightful lyrics which are to be found in his novels ; and BRYAN WALLER PROCTER ("Barry Cornwall") (b. 1787 ; d 1874), who, while he is better known for his appreciations of poetry than as a poet himself, wrote at least one good song, "The Sea."
